(b) Yield or tensile strength so determined shall be the average from three or four specimens cut from the part tested after the test is completed. The specimens shall be cut from a location where the stress during the test has not exceeded the yield strength. The specimens shall not be flame cut because this might affect the strength of material. If yield or tensile strength is not determined by test specimens from the pressure part tested, alternative methods are given in NC-6921, NC-6922, NC-6923, and NC-6924 for evaluation of proof test results to establish the Design Pressure.

(c) When excess stock from the same piece of wrought material is available and has been given the same stress relieving heat treatment as the pressure part, the test specimens may be cut from this excess stock. The specimens shall not be removed by flame cutting or any other method involving sufficient heat to affect the properties of the specimen.

NC-6911.9 Design Pressure at Higher Temperatures.

The Design Pressure for components and component parts that are to operate at temperatures at which the allowable stress value of the material is less than at the test temperature shall be determined by the following formula:

$$P_o = P_t \left(\frac{S_o}{S_t} \right)$$

where

P_o	= Design Pressure at the Design Temperature, psig
P_t	= Design Pressure at test temperature, psig
S_o	= maximum allowable stress value at the Design Temperature, psi
S_t	= maximum allowable stress value at test temperature, psi

NC-6912 Retests

A retest shall be allowed on a duplicate component or component part if errors or irregularities are obvious in the test results.

NC-6913 Witnessing of Tests by Inspector

Tests to establish the Design Pressure of components or component parts shall be witnessed and approved by the Inspector.

NC-6914 Safety Precautions

Safety of testing personnel should be given serious consideration when conducting proof tests, and particular care should be taken during bursting tests in NC-6922.

NC-6920 PROCEDURES

NC-6921 Brittle Coating Test Procedure

(a) Subject to the limitations of NC-6911.1(a), this procedure may be used only for components and component parts under internal pressure, constructed of materials having a definitely determinable yield point. The component parts that require proof testing shall be coated with a lime wash or other brittle coating in accordance with NC-6911.6. Pressure shall be applied

in accordance with NC-6911.5. The parts being proof tested shall be examined between pressure increments for signs of yielding as evidenced by flaking of the brittle coating or by the appearance of strain lines. The application of pressure shall be stopped at the first sign of yielding or, if desired, at some lower pressure.

(b) The Design Pressure P in psig at test temperature for components or component parts tested under NC-6921 shall be computed as stipulated in (1) through (4) below:

(1) if the average yield strength is determined in accordance with NC-6911.8:

$$P = 0.5H \left(\frac{Y_s}{Y_a} \right)$$

(2) to eliminate the necessity of cutting tensile specimens and determining the actual yield strength of the material under test, one of the following formulas may be used to determine the Design Pressure:

(a) for carbon steel meeting an acceptable Specification in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1 with a specified minimum tensile strength of not over 70.0 ksi (480 MPa):

$$P = 0.5H \left(\frac{S}{S + 5000} \right) \quad (1)$$

(1)

(b) for any other acceptable material listed in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1:

$$(2) P = 0.4H$$

where

H = hydrostatic test pressure at which the test was stopped, psig

Y_s	= specified minimum yield strength, psi
Y_a	= actual average yield strength from test specimens, psi
S	= specified minimum tensile strength, psi

(3) when Eq. (1) or (2) is used, the material in the pressure part shall have no appreciable cold working or other treatment that would tend to raise the yield strength above the normal value;

(4) the Design Pressure at other temperatures shall be determined as provided in NC-6911.9.

NC-6922 Bursting Test Procedure

(a) This procedure may be used for components or component parts under internal pressure when constructed of any material permitted to be used under the rules of this Subsection. The Design Pressure of any component part proof tested by this method shall be established by a hydrostatic test to failure by rupture of a full size sample of such pressure part. The hydrostatic pressure at which rupture occurs shall be determined.

(b) The Design Pressure P in psig at test temperature for parts tested under NC-6922 shall be computed as stipulated in (1) through (3) below:

(1) parts constructed of materials other than cast materials:

$$P = \frac{B}{5} \times \frac{S}{S_{ave}}$$

or

$$P = \frac{D}{5} \times \frac{S}{S_{\max}} \quad (3)$$

(3)

(2) parts constructed of cast materials, except cast iron and cast nodular iron which are not permitted:

$$P = \frac{Bf}{5} \times \frac{S}{S_{\text{ave}}}$$

or

$$P = \frac{Bf}{5} \times \frac{S}{S_{\max}} \quad (4)$$

(4)

where

B	= bursting test pressure, psig
f	= casting quality factor
S	= specified minimum tensile strength, psi
S_{ave}	= average actual tensile strength of test specimens, psi
S_{max}	= maximum tensile strength of range of specification, psi

(3) the Design Pressure at other temperatures shall be determined as provided in NC-6911.9.

NC-6923 Strain Measurement Test Procedure

(a) Subject to limitations of NC-6911.1(a), this procedure may be used for components or component parts under internal pressure, constructed of any material permitted to be used under the rules of this Subsection. Strains shall be measured in the direction of the maximum stress at the most highly stressed parts (see NC-6911.6) by means of strain gages of any type capable

Page 313

of indicating strains to 0.00005 in./in. (0.005%). Pressure shall be applied as provided in NC-6911.5.

(b) After each increment of pressure has been applied, readings of the strain gages and the hydrostatic pressure shall be taken and recorded. The pressure shall be released and any permanent strain at each gage shall be determined after any pressure increment that indicates an increase in strain for this increment over the previous equal pressure increment. Only one application of each increment of pressure is required.

(c) Two curves of strain against test pressure shall be plotted for each gage line as the test progresses, one showing the strain under pressure and one showing the permanent strain when the pressure is removed. The test may be discontinued when the test pressure reaches the value H which will, by the formula, justify the desired Design Pressure but shall not exceed the pressure at which the plotted points for the most highly strained gage line reach the value given below for the material used:

- (1) 0.2% permanent strain for aluminum-base and nickel-base alloys;
- (2) 0.2% permanent strain for carbon low alloy and high alloy steels;
- (3) 0.5% strain under pressure for copper-base alloys.

(d) The Design Pressure P in psig at test temperature for parts tested under this paragraph, shall be computed as stipulated in (1) through (3) below:

(1) if the average yield strength is determined in accordance with NC-6911.8:

$$P = 0.5H \left(\frac{Y_s}{Y_a} \right) \quad (5)$$

(5)

(2) if the actual average yield strength is not determined by test specimens:

$$P = 0.4H \quad (6)$$

(6)

where

H	= hydrostatic test pressure at which the test was stopped in accordance with (c) above, psig
Y_s	= specified minimum yield strength, psi
Y_a	= actual average yield strength from test specimens, psi

(3) the Design Pressure at other temperatures shall be determined as provided in NC-6911.9.

NC-6924 Displacement Measurement Test Procedure

(a) Subject to the limitations of NC-6911.1(a), this procedure may be used only for components and component parts

under internal pressure, constructed of materials having a definitely determinable yield point. Displacement shall be measured at the most highly stressed parts (NC-6911.6) by means of measuring devices of any type capable of measuring to 0.001 in. (0.02 mm). The displacement may be measured between two diametrically opposed reference points in a symmetrical structure or between a reference point and a fixed base point. Pressure shall be applied as provided in NC-6911.5.

(b) After each increment of pressure has been applied, readings of the displacement and hydrostatic test pressure shall be taken and recorded. The pressure shall be released and any permanent displacement shall be determined after any pressure increment that indicates an increase in measured displacement for this increment over the previous equal pressure increment. Only one application of each increment is required. Care must be taken to ensure that the readings represent only displacements of the parts on which measurements are being made and do not include any slip of the measuring devices or any movement of the fixed base points or of the pressure part as a whole.

(c) Two curves of displacement against test pressure shall be plotted for each reference point as the test progresses, one showing the displacement under pressure and one showing the permanent displacement when the pressure is removed. The application of pressure shall be stopped when it is evident that the curve through the points representing displacement under pressure has deviated from a straight line.

(d) The pressure coincident with the proportional limit of the material shall be determined by noting the pressure at which the curve representing displacement under pressure deviates from a straight line. The pressure at the proportional limit may be checked from the curve of permanent displacement by locating the point where the permanent displacement begins to increase regularly with further increases in pressure. Permanent deformation at the beginning of the curve that results from the equalization of stresses and irregularities in the material may be disregarded.

(e) The Design Pressure P in psig at test temperature for parts tested under this paragraph shall be computed as stipulated in (1) through (4) below:

(1) if the average yield strength is determined in accordance with NC-6911.8:

Page 314

$$P = 0.5H \left(\frac{Y_s}{Y_a} \right) \quad (7)$$

(7)

(2) to eliminate the necessity of cutting tensile specimens and determining the actual yield strength of the material under test, Eq. (8) or (9) may be used to determine the Design Pressure:

(a) for carbon steel, meeting an acceptable specification in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1 with a specified minimum tensile strength of not over 70.0 ksi:

$$P = 0.5H \left(\frac{S}{S + 5000} \right) \quad (8)$$

(8)

(b) for any other acceptable material listed in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1:

$$(9) P = 0.4H$$

where

H	= hydrostatic test pressure coincident with the proportional limit of the weakest element of the component part test, psig
Y_s	= specified minimum yield strength, psi
Y_a	= actual average yield strength from test specimens, psi
S	= specified minimum tensile strength, psi

(3) when Eq. (8) or (9) is used, the material in the pressure part shall have had no appreciable cold working or other treatment that would tend to raise the yield strength above the normal value;

(4) the Design Pressure at other temperatures shall be determined as provided in NC-6911.9.

NC-6930 PROCEDURE FOR COMPONENTS HAVING CHAMBERS OF SPECIAL SHAPE SUBJECT TO COLLAPSE

(a) Pressure chambers of components, portions of which have a shape other than that of a complete circular cylinder or formed head, and, also, jackets of cylindrical vessels which extend over only a portion of the circumference, which are not fully staybolted as required by NC-3133 and NC-3329, shall withstand without excessive deformation a hydrostatic test of not less than 3 times the desired Design Pressure.

(b) The Design Pressure at other temperatures shall be determined as provided in NC-6911.9.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NC-7000

ARTICLE NC-7000 OVERPRESSURE PROTECTION

Page 315

Page 316

NC-7100 GENERAL REQUIREMENTS

NC-7110 SCOPE

(a) A system¹ shall be protected from the consequences arising from the application of conditions of pressure and coincident temperature that would cause either the Design Pressure or the Service Limits specified in the Design Specification to be exceeded.

(b) Pressure relief devices² are required when the operating conditions considered in the Overpressure Protection Report would cause the Service Limits specified in the Design Specification to be exceeded.

(c) Protection of components in the system from the effects of pressure increases of extremely short duration, such as water hammer resulting from the rapid closing of a valve, is beyond the scope of this Article. These effects shall be included in the Design Specification.

NC-7111 Definitions

(a) *Overpressure*, as used in this Article, can consist of either one of the following pressure changes:

(1) an increase in system fluid pressure resulting from thermal imbalances, excess pump flow, and other similar phenomena, capable of causing a system pressure increase of a sufficient duration to be compatible with the dynamic response characteristics of the pressure relief devices listed in this Article; or

¹ Wherever the word system appears in this Article, it refers to the component or group of components for which overpressure protection is provided as described in the Overpressure Protection Report.

² A pressure relief device is designed to open to prevent a rise of internal fluid pressure greater than a specified value, resulting from exposure to pressure transient conditions. It may also be designed to prevent excessive internal vacuum. It may be a pressure relief valve, a nonreclosing pressure relief device, or a vacuum relief valve.

(2) changes in differential pressure resulting from thermal imbalances, vapor condensation, and other similar phenomena, capable of causing an internal or external pressure increase of sufficient duration to be compatible with the dynamic response characteristics of the pressure relief devices listed in this Article.

(b) The basic definitions of pressure relief devices as specified in this Article are in accordance with ASME PTC 25 -1994, Pressure Relief Devices.

(c) *Primary pressure* is the pressure of the fluid at the inlet of the pressure relief device.

(d) *Secondary pressure* is that value of pressure existing in the passage between the actual discharge area and the outlet for which the discharge system of the pressure relief devices shall be designed.

NC-7120 INTEGRATED OVERPRESSURE PROTECTION

Overpressure protection of the system shall be provided by any of the following methods as an integrated overpressure protection:

(a) the use of pressure relief devices and associated pressure sensing elements;

(b) a design without pressure relief devices that does not exceed the Service Limits specified in the Design Specifications [NC-7110(b)].

NC-7130 VERIFICATION OF THE OPERATION OF RECLOSING PRESSURE RELIEF DEVICES

NC-7131 Construction

(a) Reclosing pressure relief devices shall be constructed so that potential impairment of the overpressure protection function from service exposure to fluids can be determined by test or examination.

(b) Reclosing pressure relief devices and their associated pressure sensing elements shall be so constructed that their correct operation can be demonstrated under service or test conditions, as may be required by regulatory and enforcement authorities having jurisdiction at the nuclear power plant site.

NC-7140 INSTALLATION

NC-7141 Pressure Relief Devices

- (a)* Pressure relief devices shall be as close as practicable to the major source of overpressure anticipated to arise within the system under the conditions summarized in the Overpressure Protection Report (NC-7200).
- (b)* The connection between a system and its pressure relief device shall have a minimum inside diameter equal to or greater than nominal inside diameter of the pressure relief device inlet. The opening in the connection shall be designed to provide direct and unobstructed flow between the system and the pressure relief device.
- (c)* The connection between a system and its safety valve shall be not longer than the face-to-face dimension of the corresponding tee fitting of the same dimension and pressure rating listed in ASME B16.5, ASME B16.9, or ASME B16.11. Alternatively, the connection shall not result in accumulative line losses greater than 2% of the relieving pressure.
- (d)* The connection between a system and its safety relief valve or relief valve shall not result in accumulated line losses greater than 3% of the relieving pressure.
- (e)* Safety, safety relief, and relief valves shall be installed in an upright position.
- (f)* The flow area of the discharge piping connected to a pressure relief device shall not be less than the flow area of the device outlets. Back pressure that may exist or develop shall not reduce the relieving capacity of the relieving device(s) below that required to protect the system; potential for flashing shall be considered.
- (g)* Valve installation not in accordance with (c), (d), (e), and (f) above may be used provided:
 - (1)* the NV Certificate Holder confirms that the valve design is satisfactory for the intended installation and satisfies the requirements of the valve Design Specification;
 - (2)* the valves are adjusted for acceptable performance and in conformance with the requirements of the valve Design Specification;
 - (3)* technical justification for the adequacy of the installation is provided in the Overpressure Protection Report, including verification that the requirements of (1) and (2) have been met.

NC-7142 Stop Valves

- (a)* No stop valve or other device shall be placed in such a location, relative to a pressure relief device, that it could reduce the overpressure protection below that required by the rules of this Article, unless such stop valves are constructed and installed with controls and interlocks so that the relieving capacity requirements of NC-7300 are met under all conditions of operation of both the system and the stop valves.
- (b)* Simple administrative control of stop valve position is not acceptable.
- (c)* Stop valves shall have independent and diverse interlocks to prevent valves from being closed during all conditions of system operation when the pressure relief device is needed to meet the requirements of NC-7300.
- (d)* Stop valves shall have independent and diverse interlocks to assure that the valves will automatically open and remain open during all conditions of system operation when the pressure relief device is needed to meet the requirements of NC-7300.
- (e)* Means shall be provided to permit verification of the operation of controls and interlocks.

NC-7143 Draining of Pressure Relief Devices

- (a)* A pressure relief device installation shall be fitted with a drain at its lowest point where liquid or residue can collect if such liquid or residue could interfere with proper relieving operation.
- (b)* If the design of a pressure relief device permits liquid or residue to collect on the discharge side of the disk and could interfere with proper relieving operation, the device shall be fitted with a drain to minimize the collection of liquid or

residue.

NC-7150 ACCEPTABLE PRESSURE RELIEF DEVICES

NC-7151 Pressure Relief Valves³

Pressure relief valves may be used in accordance with NC-7170 and NC-7500.

NC-7152 Vacuum Relief Valves

Vacuum relief valves may be used in accordance with NC-7170 and NC-7500.

NC-7153 Nonreclosing Pressure Relief Devices⁴

Nonreclosing pressure relief devices may be used in accordance with NC-7170 and NC-7600.

3 A pressure relief valve is a pressure relief device which is designed to reclose and prevent the further flow of fluid after normal conditions have been restored.

4 A nonreclosing pressure relief device is a pressure relief device designed to remain open after operation.

Page 323

NC-7160 UNACCEPTABLE PRESSURE RELIEF DEVICES

NC-7161 Deadweight Pressure Relief Valves

Deadweight valves shall not be used.

NC-7170 PERMITTED USE OF PRESSURE RELIEF DEVICES

NC-7171 Safety Valves⁵

Safety valves, meeting the requirements of NC-7510, may be used for:

- (a) steam service;
- (b) air and gas service.

NC-7172 Safety Relief Valves⁶

Safety relief valves, meeting the requirements of NC-7510, may be used for:

- (a) steam service;
- (b) air and gas service;
- (c) liquid service.

NC-7173 Relief Valves⁷

Relief valves, meeting the requirements of NC-7510, may be used for liquid service.

NC-7174 Pilot Operated Pressure Relief Valves⁸

Pilot operated pressure relief valves, meeting the requirements of NC-7520, may be used for:

- (a) steam service;
- (b) air and gas service, provided that the design is such that the main valve will open automatically at not over the set pressure and will not discharge its full rated capacity if some essential part of the actuator should fail;
- (c) liquid service.

5 A safety valve is a pressure relief valve actuated by inlet static pressure and characterized by rapid opening or pop action.

6 A safety relief valve is a pressure relief valve characterized by rapid opening or pop action, or by opening generally proportional to the increase in pressure over the opening pressure.

7 A relief valve is a pressure relief valve actuated by inlet static pressure and having a gradual lift generally proportional to the increase in pressure over the opening pressure.

8 A pilot operated pressure relief valve is a pressure relief valve in which the major relieving device is combined with and controlled by a self-actuated auxiliary pressure relief valve.

NC-7175 Power Actuated Pressure Relief Valves⁹

Power actuated pressure relief valves, meeting the requirements of NC-7530, may be used for:

(a) steam service;

(b) air and gas service, provided that the design is such that the main valve will open automatically at not over the set pressure and will not discharge its full rated capacity if some essential part of the pilot should fail;

(c) liquid service.

NC-7176 Safety Valves With Auxiliary Actuating Devices

Safety valves with auxiliary actuating devices, meeting the requirements of NC-7540, may be used for steam service.

NC-7177 Vacuum Relief Valves¹⁰

Vacuum relief valves, meeting the requirements of NC-7550, may be used for air and gas service.

NC-7178 Nonreclosing Devices

Rupture disk devices¹¹ may be used on air, gas, or steam service, except for main steam service, in accordance with NC-7600.

NC-7200 OVERPRESSURE PROTECTION REPORT

NC-7210 RESPONSIBILITY FOR REPORT

The provisions intended to meet the requirements of this Article shall be the subject of an Overpressure Protection Report prepared by the Owner or his Designee.

9 A power actuated pressure relief valve is a pressure relief valve in which the major relieving device is combined with and controlled by a device requiring an external source of energy.

10 A vacuum relief valve is a pressure relief device designed to admit fluid to prevent an excessive internal vacuum; it is designed to reclose and prevent further flow of fluid after normal conditions have been restored.

11 A rupture disk device is a nonreclosing pressure relief device actuated by inlet static pressure and designed to function by the bursting of a pressure containing disk.

Page 324

NC-7220 CONTENT OF REPORT

The Overpressure Protection Report shall define the protected systems and the integrated overpressure protection provided. As a minimum, the report shall include the following:

(a) identification of specific ASME Section III, Article NC-7000, Edition and Addenda and applicable Code Cases used in the design of the overpressure protection system;

(b) drawings showing arrangement of protected systems including the pressure relief devices;

(c) the analysis of the effect of the range of operating conditions, including the effect of discharge piping back pressure;

(d) an analysis of the conditions that give rise to the maximum pressure or vacuum relieving requirements, except when the basis for establishing relieving capacity is the loss of the heat sink of the protected system when the thermal input to the system is at a maximum;

- (e) the relief capacity required to prevent a pressure or vacuum rise in any component from exceeding the limitations of NC-7300;
- (f) the operating controls or safety controls of the protected system upon which the anticipated required relief capacity of (d) and the maximum pressure, vacuum, and temperature of (c) are predicted;
- (g) the redundancy and independence of the pressure relief devices and their associated pressure or vacuum sensors and controls employed to preclude a loss of overpressure protection in the event of a failure of any pressure relief device, sensing element, associated control, or external power sources;
- (h) the extent that an individual component can be isolated from the overall system overpressure protection and the analysis of the conditions under which additional individual overpressure protection is necessary;
- (i) the design secondary pressure including a justification of the value identified in the Design Specification for pressure relief devices;
- (j) the analysis of pressure transient conditions, including those associated with the response time of pressure or vacuum relief valves, taking into account the effect of liquid and two-phase flow;
- (k) consideration of set pressure and blowdown limitations, taking into account opening pressure tolerances and overpressure of the pressure relief device;
- (l) consideration of burst pressure tolerance and manufacturing design range of the rupture disk device;
- (m) verification that pressure relief devices are not required, if applicable. Verification shall include reference to each component's Design Report and applicable requirements in NC-3000 that demonstrate the calculated stress levels do not exceed the Service Limits specified in the component Design Specification for all system service loadings.

NC-7230 CERTIFICATION OF REPORT

The Report, after it has been reconciled with the requirements of this Article, shall be certified by one or more Registered Professional Engineers competent in the applicable field of design and qualified in accordance with the requirements of Appendix XXIII.

NC-7240 REVIEW OF REPORT AFTER INSTALLATION

- (a) Any modification of the installation from that used for the preparation of the Overpressure Protection Report shall be reconciled with the Overpressure Protection Report.
- (b) Modifications shall be documented in an addendum to the Overpressure Protection Report. The addendum shall contain a copy of the as-built drawing and shall include either:
- (1) a statement that the as-built system meets the requirements of the Overpressure Protection Report; or
 - (2) a revision to the Overpressure Protection Report to make it agree with the as-built system; or
 - (3) a description of the changes made to the as-built system to make it comply with the Overpressure Protection Report.
- (c) The addendum shall be certified by one or more Registered Professional Engineers competent in the applicable field of design and qualified in accordance with the requirements of Appendix XXIII.

NC-7250 FILING OF REPORT

A copy of the Overpressure Protection Report shall be filed at the nuclear power plant site prior to the Inspector signing the Owner's Data Report. The report shall be made available to the Authorized Inspector and the regulatory and enforcement authorities having jurisdiction at the nuclear power plant site.

NC-7300 RELIEVING CAPACITY REQUIREMENTS

NC-7310 EXPECTED SYSTEM PRESSURE TRANSIENT CONDITIONS

[98]

NC-7311 Relieving Capacity of Pressure Relief Devices

(a) The total relieving capacity of the pressure relief devices (certified in accordance with NC-7700, intended for overpressure protection within the scope of this Subsection, and credited in conformance with NC-7500 or NC-7600) shall take into account any losses due to fluid flow through piping and other components.

(b) The total relieving capacity shall be sufficient to prevent a rise in pressure of more than 10% or 3 psi, whichever is greater, above the Design Pressure of any component within the pressure retaining boundary of the protected system under any expected system pressure transient conditions as summarized in the Overpressure Protection Report (NC-7200).

(c) The rated capacity of each vacuum relief valve shall not be less than that required to prevent a differential pressure in excess of the value specified in the Design Specification and in the Overpressure Protection Report.

[98]

NC-7312 Relieving Capacity of Pressure Relief Devices Used With Pressure Reducing Devices

When using pressure reducing devices, the combined relieving capacity of the pressure relief devices shall be sufficient to meet the requirements of NC-7311 when:

(a) pressure reducing devices and their bypass valves are fully open, and;

(b) all discharge paths are blocked on the low pressure side of the pressure reducing device.

NC-7313 Required Number and Capacity of Pressure Relief Devices

(a) The required relieving capacity for main steam and feedwater systems within the scope of this Subsection shall be provided by the use of at least two pressure relief devices.

12 Expected system pressure transient conditions are those associated with normal system transient operation.

(b) Other systems or components requiring individual protection may be served by one or more devices except when power actuated pressure relief valves are used, in which case at least two valves shall be used to contribute to the required relieving capacity.

(c) When more than one device is used, no device shall have a capacity less than 50% of the device with the largest capacity.

NC-7314 Required Number and Capacity of Pressure Relief Devices for Isolatable Components Requiring Overpressure Protection

The required relieving capacity for overpressure protection of an isolatable component shall be provided by the use of at least one pressure relief device meeting the requirements of NC-7500 or NC-7600.

NC-7315 Relieving Capacity of Vacuum Relief Valves

(a) The capacity of each vacuum relief valve shall not be less than that required to prevent a differential pressure in excess of the value specified in the Design Specification.

(b) At least two independent vacuum relief valves shall be provided on each system. The capacity of each vacuum relief valve shall not be less than that required to protect the system.

(c) Systems designed to withstand the maximum differential pressure do not require vacuum relief valves.

NC-7320 UNEXPECTED SYSTEM EXCESS PRESSURE TRANSIENT CONDITIONS¹³

[98]

NC-7321 Relieving Capacity of Pressure Relief Devices

(a) The total relieving capacity of the pressure relief devices (certified in accordance with NC-7700, intended for overpressure protection within the scope of this Subsection, and credited in conformance with NC-7500 or NC-7600) shall take into account any losses due to fluid flow through piping and other components.

13Unexpected system excess pressure transient conditions are those associated with unusual or abnormal system transients, but still considered to be within the design basis.

(b) The total relieving capacity shall be sufficient to prevent a rise in pressure of more than 10% or 3 psi, whichever is greater, above the Design Pressure of any component within the pressure retaining boundary of the protected system under each of the unexpected

Page 326

system excess pressure transient conditions specified in the Overpressure Protection Report.

[98]

NC-7322 Relieving Capacity of Vacuum Relief Valves

(a) The capacity of each vacuum relief valve shall not be less than that required to prevent a differential pressure in excess of the value specified in the Design Specification of the system being protected.

(b) At least two independent vacuum relief valves shall be provided on each system. The capacity of each vacuum relief valve shall not be less than that required to protect the system.

(c) Systems designed to withstand the maximum differential pressure do not require vacuum relief valves.

NC-7330 SYSTEM FAULTED CONDITIONS

This Article does not provide rules for overpressure protection of system faulted conditions.

NC-7400 SET PRESSURES OF PRESSURE RELIEF DEVICES

NC-7410 SET PRESSURE LIMITATIONS FOR EXPECTED SYSTEM PRESSURE TRANSIENT CONDITIONS

The stamped set pressure of at least one of the pressure relief devices connected to the system shall not be greater than the Design Pressure of any component within the pressure retaining boundary of the protected system. Additional pressure relief devices may have higher stamped set pressure settings, but in no case shall these set pressures be such that the total system pressure exceeds the system limitations specified in NC-7310.

NC-7420 SET PRESSURE LIMITATION FOR UNEXPECTED SYSTEM EXCESS PRESSURE TRANSIENT CONDITIONS

The establishment of the stamped set pressure shall take into account the requirements of NC-7320.

NC-7500 OPERATING AND DESIGN REQUIREMENTS FOR PRESSURE AND VACUUM RELIEF VALVES

NC-7510 SAFETY, SAFETY RELIEF, AND RELIEF VALVES

NC-7511 General Requirements

NC-7511.1 Spring Loaded Valves.

Valves shall open automatically by direct action of the fluid pressure as a result of forces acting against a spring.

NC-7511.2 Balanced Valves.

Balanced valves, whose operation is independent of back pressure, may be used if means are provided to verify the integrity of the balancing device.

[98]

NC-7511.3 Antisimmer-Type Valves.

Valves that are fitted with antisimmer devices that serve to raise the set pressure of the valve during normal operation of the system may be used, provided:

(a) the design is such that the valve opens automatically and discharges its certified capacity at 10% or 3 psi, whichever is greater, of the system design pressure in the event any item of the auxiliary loading device should fail;

(b) the operating signal and energy source provisions are such that the valve reverts to its normal set pressure in the event of any failure of signal or loss of energy source;

(c) the auxiliary loading force imposed on such valves does not raise the set pressure of the valve by more than 10% or 3 psi, whichever is greater;

(d) the auxiliary loading force which augments the force exerted by the valve spring is automatically unloaded at a pressure not greater than the set pressure of the valve.

[98]

NC-7512 Safety Valve Operating Requirements

NC-7512.1 Antichattering and Lift Requirements

(a) Safety valves shall be constructed to operate without chattering and to attain rated lift at a pressure which does not exceed the set pressure by more than 3% or 2 psi (13.8 kPa), whichever is greater.

(b) For valves used for main steam service, conformance with (a) above shall be established for each production valve by testing on steam at the stamped set pressure. The test shall take into account valve discharge piping back pressure as specified in the valve Design Specification.

Page 327

NC-7512.2 Set Pressure Tolerance

(a) The set pressure tolerance plus or minus shall not exceed the following: 2 psi (13.8 kPa) for pressures up to and including 70 psi (483 kPa), 3% for pressures over 70 psi (483 kPa) up to and including 300 psi (2070 kPa), 10 psi (69 kPa) for pressures over 300 psi (2070 kPa) up to and including 1000 psi (6900 kPa), and 1% for pressures over 1000 psi (6900 kPa). The set pressure tolerance shall apply unless a greater tolerance is established as permissible in the Overpressure Protection Report (NC-7200) and in the safety valve Design Specification (NCA-3250).

(b) Conformance with the requirements of (a) shall be established for each production valve by test. Steam valves shall be tested on steam.

NC-7512.3 Blowdown

(a) Safety valves shall be adjusted to close after blowing down to a pressure not lower than that specified in the valve Design Specification (NCA-3250) and the basis for the setting is covered in the Overpressure Protection Report (NC-7200).

(b) For valves used for main steam service, conformance with (a) shall be established for each production valve by testing on steam at the stamped set pressure. The test shall take into account valve discharge piping back pressure as specified in the valve Design Specification (NCA-3250).

(c) For valves used for other than main steam service, the adjustment shall be determined by test or proration from the Certificate Holder's blowdown test data.

NC-7513 Safety Relief and Relief Valve Operating Requirements

Safety relief and relief valves shall be constructed to attain rated lift at a pressure which does not exceed the set pressure

by more than 10% or 3 psi (20.6 kPa), whichever is greater.

NC-7513.1 Set Pressure Tolerance

(a) The set pressure tolerance plus or minus from the set pressure of safety relief and relief valves shall not exceed 2 psi (13.8 kPa) for pressures up to and including 70 psi and 3% for pressures above 70 psi (483 kPa).

The set pressure tolerance shall apply unless a greater tolerance is established as permissible in the Overpressure Protection Report (NC-7200) and in the valve Design Specification (NCA-3250).

(b) Conformance with the requirements of (a) shall be established for each production valve by test. Steam valves shall be tested on steam, air or gas valves on air or gas, and liquid valves on liquid.

NC-7513.2 Blowdown.

Safety relief and relief valves shall be adjusted to close after blowing down to a pressure not lower than that specified in the valve Design Specification (NCA-3250) and the basis for the setting shall be covered in the Overpressure Protection Report (NC-7200). The adjustment shall be determined by test or by proration from the Certificate Holder's blowdown test data.

NC-7514 Credited Relieving Capacity

The credited relieving capacity of safety, safety relief, and relief valves shall be based on the certified relieving capacity. In addition, the capacity can be prorated as permitted by NC-7700.

NC-7515 Sealing of Adjustments

Means shall be provided in the design of all valves for sealing all adjustments or access to adjustments which can be made without disassembly of the valve. For a pilot operated pressure relief valve, an additional seal shall be provided to seal the pilot and main valve together. Seals shall be installed by the Certificate Holder at the time of initial adjustment. Seals shall be installed in a manner to prevent changing the adjustment or disassembly of the valve without breaking the seal. The seal shall serve as a means of identifying the Certificate Holder making the initial adjustment.

NC-7520 PILOT OPERATED PRESSURE RELIEF VALVES

NC-7521 General Requirements

Pilot operated pressure relief valves shall operate independently of any external energy source.

NC-7522 Operating Requirements

NC-7522.1 Actuation.

The pilot control device shall be actuated directly by the fluid pressure of the protected system.

NC-7522.2 Response Time.

The Overpressure Protection Report (NC-7200) shall include the effects of divergence between opening (set) and closing (blowdown) pressures of the pilot valve and the pressures at which the main valve attains rated lift and closes. These divergences are caused by the inherent time delay (e.g., response time) between the operation of the pilot and the main valve, and the rate of the system

Page 328

pressure change. The limits for response time shall be specified in the Design Specification (NCA-3250).

NC-7522.3 Main Valve Operation.

The main valve shall operate in direct response to the pilot control device. The valve shall be constructed to attain rated lift under stable conditions at pressures which do not exceed the set pressure by more than 3% or 2 psi (13.8 kPa),

whichever is greater, for steam, and 10% or 3 psi (20.6 kPa), whichever is greater, for air, gas, or liquid service.

NC-7522.4 Sensing Mechanism Integrity.

For other than spring loaded direct acting pilot control devices, means shall be provided to detect failure of the pressure sensing element, such as bellows, when operation of the pilot control device is dependent upon the integrity of a pressure sensing element.

NC-7522.5 Set Pressure Tolerance

- (a) The set pressure tolerance shall apply only to the pilot valve.
- (b) The set pressure tolerance plus or minus shall not exceed the following:
 - (1) 2 psi (13.8 kPa) for pressures up to and including 70 psi (483 kPa);
 - (2) 3% for pressures over 70 psi (483 kPa) up to and including 300 psi (2070 kPa);
 - (3) 10 psi (69 kPa) for pressures over 300 psi (2070 kPa) up to and including 1000 psi (6900 kPa); and
 - (4) 1% for pressures over 1000 psi for steam, air, and gas valves.

The set pressure tolerance as stated shall apply unless a greater tolerance is established as permissible in the Overpressure Protection Report (NC-7200) and the valve Design Specification.

(c) Conformance with the requirements of (b) above shall be established for each production valve by test. Steam valves shall be tested on steam, air or gas valves on air or gas, and liquid valves on liquid.

NC-7522.6 Blowdown

- (a) The blowdown requirements shall only apply to the pilot valve.
- (b) Pilot valves shall be adjusted to close after blowing down to a pressure not lower than that specified in the valve Design Specification (NCA-3250) and the basis for the setting is covered in the Overpressure Protection Report (NC-7200).
- (c) The adjustment shall be determined by test or by proration from the Certificate Holder's blowdown test data.

NC-7523 Credited Relieving Capacity

Except as required in NC-7523.1 and NC-7523.2, the credited relieving capacity of pilot operated pressure relief valves shall be based on the certified relieving capacity. In addition, the capacity may be prorated as permitted in NC-7700.

NC-7523.1 System Upset Conditions.

For system upset conditions in main steam service, the relieving capacity with which these values are credited shall be not more than:

- (a) the stamped relieving capacity of the smaller one when two valves are installed;
- (b) the stamped relieving capacity of the smaller two where three valves are installed;
- (c) three-fourths of the total stamped relieving capacity where more than three valves are installed.

NC-7523.2 System Emergency Conditions.

For system emergency conditions in main steam service, the relieving capacity with which these valves are credited shall be not more than:

- (a) the relieving capacity of the valve with smaller stamped capacity where two valves are installed;
- (b) the relieving capacity of all except the valve with the largest stamped capacity where more than two valves are

installed.

NC-7524 Sealing of Adjustments

The sealing requirements of NC-7515 shall apply.

NC-7530 POWER ACTUATED PRESSURE RELIEF VALVES

NC-7531 General Requirements

Power actuated pressure relief valves, which depend upon an external energy source such as electrical, pneumatic, or hydraulic systems and which respond to signals from pressure or temperature sensing devices, may be used, provided the requirements of this Subsubarticle are met.

NC-7532 Operating Requirements

NC-7532.1 Response Time.

In systems protected by power operated pressure relief valves, consideration shall be given to the time lapse between the signal to open and achieving the fully opened position, and the time lapse between the signal to close and achieving the fully closed position.

Page 329

NC-7532.2 Sensors, Controls, and External Energy Sources

(a) The sensors, controls, and external energy sources for valve operation shall have redundancy and independence at least equal to that required for the control and safety protection systems associated with the system.

(b) The relief valve and its auxiliary devices treated as a combination shall comply with the following requirements.

(1) The valve opening pressure shall be controlled within a tolerance of $\pm 1\%$ of the set pressure when the automatic control is in use.

(2) The valve blowdown shall be controlled to a pressure not lower than that specified in the valve Design Specification (NCA-3250).

NC-7533 Certified Relieving Capacity

The power actuated pressure relief valve certified relieving capacity and the proration of capacity shall be as determined by NC-7700.

NC-7534 Credited Relieving Capacity

NC-7534.1 Expected System Pressure Transient Conditions.

For expected system pressure transient conditions, the relieving capacity with which these valves are credited shall be not more than:

(a) the certified relieving capacity of the smaller one when two valves are installed;

(b) one-half of the total certified relieving capacity when three or more valves are installed.

NC-7534.2 Unexpected System Excess Pressure Transient Conditions.

For unexpected system excess pressure transient conditions, the relieving capacity with which these valves are credited shall not be more than:

(a) the relieving capacity of the valve with the smaller stamped capacity where two valves are installed;

(b) the relieving capacity of all except the valve with the largest certified capacity for valves where three through ten

valves are installed;

(c) the relieving capacity of all except two valves of the largest certified capacity where more than ten valves are installed.

NC-7540 SAFETY VALVES WITH AUXILIARY ACTUATING DEVICES

NC-7541 General Requirements

Safety valves with auxiliary actuating devices which operate independently of the spring loading of the valve may be used, provided the requirements of NC-7510 are met except as modified by this Subsubarticle.

NC-7542 Construction

(a) The construction shall be such that the valve opens automatically by direct action of the fluid at a pressure not higher than the safety valve set pressure and relieves at the relieving capacity in the event of failure of any essential part of the valve's auxiliary devices.

(b) The construction of the auxiliary actuating device shall be such that the safety valve will not be prevented from operating as defined in NC-7510 when the auxiliary actuating device is deenergized.

NC-7543 Expected System Pressure Transient Conditions

For expected system pressure transient conditions, credit for capacity (NC-7546) can be taken for valves opening at the setpoint of the auxiliary actuating device in accordance with (a) and (b) below.

(a) When two valves are installed, the valve of the smaller certified capacity is credited with opening at the setpoint of the auxiliary actuating device. The valve with the larger certified capacity is credited with opening at the safety valve set pressure.

(b) For groups of more than two valves all of the same certified capacity, half the valves in a group containing an even number of valves, or the number of valves in the group minus one and divided by two for a group containing an odd number of valves, are credited with opening at the setpoint of the auxiliary actuating device.

NC-7544 Unexpected System Excess Pressure Transient Conditions

For unexpected system excess pressure transient conditions, credit for capacity may be taken for valves opening at the setpoint of the auxiliary actuating device in accordance with the following.

(a) When two valves are installed, the valve with the smaller certified capacity may be credited with opening at the setpoint of the auxiliary actuating device. The valve with the larger certified capacity shall be credited with opening at the safety valve set pressure.

(b) When three through ten valves are installed, credit may be given for opening at the setpoint of the auxiliary actuating device for all valves except the one with the largest certified capacity. The valve assumed not to open at the setpoint of the auxiliary actuating device

Page 330

shall be credited with opening at the safety valve set pressure.

(c) When more than ten valves are installed, credit may be given for opening at the setpoint of the auxiliary actuating device for all valves except for two of the largest certified capacity. The two valves assumed not to open at the setpoint of the auxiliary actuating device shall be credited with opening at the safety valve set pressure.

NC-7545 Auxiliary Device Sensors and Controls

The sensors, controls, and external energy sources for the auxiliary actuating device shall comply with the requirements of NC-7530.

NC-7546 Certified Relieving Capacity

The certified relieving capacity and proration of capacity for safety valves with auxiliary actuating devices shall be determined by NC-7700.

NC-7547 Credited Relieving Capacity

The relieving capacities with which these valves are credited shall be:

(a) for valves credited with opening at the auxiliary actuating device setpoint, the capacity at the lower relieving pressure as determined by the rules of NC-7700 (this shall specifically include the 90% of average tested capacity inherent in the Code Certification procedure);

(b) for valves credited with opening at the safety valve set pressure, the stamped capacity as determined by the rules of NC-7700.

NC-7548 Response Time

For valves credited with opening at the auxiliary actuating device setpoint, consideration shall be given to the time delay between the signal to open and achieving the fully opened position and the time delay between the signal to close and achieving the fully closed position.

NC-7550 VACUUM RELIEF VALVES

NC-7551 General Requirements

Vacuum relief valves shall meet the construction requirements applicable to Class 2 valves and the additional requirements of this Article.

NC-7552 Types Permitted

(a) Balanced self-actuating horizontally installed swinging disk valves are permitted.

(b) Vertically installed vacuum disk or pallet-type valves are permitted.

(c) All vacuum relief valves shall have provisions for adjustment of the differential pressure.

NC-7553 Operating Requirements

Vacuum relief valves, which are operated by indirect means depending on an external energy source, such as electrical, pneumatic, or hydraulic systems, are not acceptable unless at least two independent external power-operated valves and control systems are employed so that the required relieving capacity is obtained if any one of the valves or systems should fail to operate.

NC-7600 NONRECLOSING PRESSURE RELIEF DEVICES

NC-7610 RUPTURE DISK DEVICES

NC-7611 General Requirements

Rupture disk devices certified in accordance with NC-7720 and NC-7750 are subject to the following:

(a) rupture disk devices may be used as the sole pressure relief devices, except for main steam or liquid service (NC-7625);

(b) rupture disk devices may be used on the inlet side of pressure relief valves only when such valves are of the full bore¹⁴ type (NC-7623);

(c) rupture disk devices may be used in conjunction with pressure relief valves on the outlet side (NC-7624).

¹⁴ A pressure relief valve which has no protrusions in the bore and wherein the valve disk lifts to an extent sufficient for the minimum area, at any section at or below the body seat, to become the

NC-7612 Burst Pressure Tolerance

The burst pressure tolerance at the specified disk temperature¹⁵ shall not exceed ± 2 psi for stamped burst pressure up to and including 40 psi and $\pm 5\%$ for stamped burst pressure above 40 psi as established by the rules of NC-7613, unless other values have

Page 331

been established in the Design Specification and are covered in the Overpressure Protection Report.

NC-7613 Tests to Establish Stamped Burst Pressure

(a) Every rupture disk shall have a stamped burst pressure established by rules of NC-7612 within a manufacturing design range,¹⁶ at a specified disk temperature, and shall be stamped with a lot number.

(b) Each lot of rupture disks¹⁷ shall be tested in accordance with one of the following methods. All tests of disks for a given lot shall be made in a holder of the same form and pressure area dimensions as that being used in service.

(1) At least two sample rupture disks from each lot of rupture disks shall be burst at the specified disk temperature. The stamped burst pressure shall be determined so that the sample rupture disk burst pressures are within the tolerance specified by NC-7612.

(2) At least four sample rupture disks, but not less than 5% from each lot of rupture disks, shall be burst at four different temperatures distributed over the applicable temperature range for which the disks will be used. These data shall be used to establish a smooth curve of burst pressure vs. temperature for the lot of disks. The burst pressure for each data point shall not deviate from the curve more than the burst pressure tolerance specified in NC-7612.

The value for the stamped burst pressure shall be established from the curve for a specified disk temperature.

(3) For prebulged solid metal disks or graphite disks only, at least four sample rupture disks using one size of disk from each lot of material shall be burst at four different temperatures, distributed over the applicable temperature range for which this material will be used. These data shall be used to establish a smooth curve of burst pressure vs. temperature for the lot of material. The burst pressure for each data point shall not deviate from the curve more than the burst pressure tolerance specified in NC-7612.

16 The manufacturing design range is a range of pressure within which the stamped burst pressure must fall. This range is included in the Design Specification and the Overpressure Protection Report.

17 A lot of rupture disks is those disks manufactured of material at one time, of the same size, thickness, type, heat, and manufacturing process including heat treatment.

At least two disks from each lot of disks, made from this lot of material and of the same size as those to be used, shall be burst at the ambient temperature to establish the room rating of the lot of disks. The curve shall be used to establish the stamped rating at the specified disk temperature for the lot of disks.

NC-7614 Burst Pressure in Relation to Pressure Relief Valve Set Pressure

The burst pressure of a rupture disk may be either lower or higher than the set pressure of the associated pressure relief valve, but in no case shall the rupture disk burst pressure and valve set pressure be such that the total accumulated pressure during full capacity relief exceeds the permitted limit (NC-7400).

NC-7620 INSTALLATION REQUIREMENTS

NC-7621 Provisions for Venting or Draining

When a rupture disk is used in conjunction with a pressure relief valve, the space between the rupture disk and the associated pressure relief valve shall be vented and/or drained. This space shall be provided with means to monitor its internal pressure during service periods.

NC-7622 System Obstructions

When the release of rupture disk material may occur, piping and other components downstream of the rupture disk shall be constructed such that no obstruction can be caused nor the function of a pressure relief valve impaired.

NC-7623 Rupture Disk Devices at the Inlet Side of Pressure Relief Valves

A rupture disk device may be installed at the inlet side of a pressure relief valve if the following provisions are met:

- (a) the combination of the pressure relief valve and the rupture disk device capacity shall meet the requirements of NC-7300;
- (b) the stamped burst pressure at the specified disk temperature of the rupture disk does not exceed the limits of NC-7400 ;
- (c) the opening provided through the rupture disk after burst is sufficient to permit a flow equal to the capacity of the valve, and there is no chance of interference with proper functioning of the valve; but in no case shall this area be less than the area of the inlet of the valve unless the capacity and functioning of the specific combination of rupture disk and valve have been established by test in accordance with NC-7700.

Page 332

NC-7624 Rupture Disk Devices at the Outlet Side of Pressure Relief Valves

A rupture disk device may be installed at the outlet side of pressure relief valves if the following provisions are met:

- (a) the set pressure of the valve is independent of back pressure; or for unbalanced valves the set pressure of the valve plus the stamped burst pressure of the rupture disk plus any pressure in the outlet piping does not exceed the limits of NC-7400;
- (b) the relieving capacity meets the requirements of NC-7300;
- (c) the stamped burst pressure of the rupture disk at the specified disk temperature plus any pressure in the outlet piping from the rupture disk device shall not exceed the secondary Design Pressure of the pressure relief valve and the Design Pressure of any pipe or fittings between the valve and the rupture disk device. However, in no case shall the stamped burst pressure of the rupture disk at the operating temperature plus any pressure in the outlet piping from the rupture disk device exceed the limits of NC-7400;
- (d) the opening provided through the rupture disk device after burst is sufficient for the pressure relief valve to flow its certified capacity.

NC-7625 Rupture Disk Devices Used as Sole Pressure Relief Device

Rupture disk devices may be used as the sole pressure relief device if the following provisions are met:

- (a) at least two rupture disk devices are used in series as the sole pressure relief device for services where release of the contents of the protected system is acceptable to the enforcement authorities having jurisdiction at the nuclear power plant site;
- (b) the rupture disk device is sized to meet the requirements of NC-7300;
- (c) the stamped burst pressure at the specified temperature of the rupture disk does not exceed the limits of NC-7400;
- (d) the space between the two rupture disk devices is monitored for pressure buildup, and a means of draining and/or venting is provided to check for rupture disk leakage or burst¹⁸
- (e) the distance between the rupture disks is designed so that the first disk will not contact the second disk at rupture.

¹⁸ Rupture disks will not burst at Design Pressure if back pressure builds up in the space between the two rupture disks. This will occur should leakage develop in the rupture disk due to corrosion or other causes.

NC-7700 CERTIFICATION

NC-7710 RESPONSIBILITY FOR CERTIFICATION OF PRESSURE AND VACUUM RELIEF VALVES

(a) The Certificate Holder shall be responsible for having the relieving capacity of his valves certified as prescribed in this Subarticle.

(b) Capacity certification which is obtained in compliance with other Subsections and which complies with this Subsection may be considered as qualified for capacity certification under the rules of this Subsection, and the valve may be stamped with the appropriate symbol of this Subsection.

NC-7720 RESPONSIBILITY FOR CERTIFICATION OF NONRECLOSING PRESSURE RELIEF DEVICES

When rupture disk devices are used at the inlet of pressure relief valves, the manufacturer of the rupture disk devices or Certificate Holder shall be responsible for having the relieving capacity of the combination determined.

NC-7730 CAPACITY CERTIFICATION OF PRESSURE RELIEF VALVES - COMPRESSIBLE FLUIDS

NC-7731 General Requirements

NC-7731.1 Capacity Certification.

Capacity certification procedures shall be as required in NC-7732 through NC-7737.

NC-7731.2 Test Media

(a) Capacity certification tests of pressure relief valves for steam service shall be conducted with dry saturated steam. For test purposes, the limits of 98% minimum quality and 20°F maximum superheat shall apply. Capacity shall be corrected to the dry saturated condition from within these limits.

(b) Capacity certification tests for pressure relief valves for air and gas service shall be conducted with air, gas, or dry saturated steam.

[98]

NC-7731.3 Test Pressure

(a) Capacity certification tests of pressure relief valves for main steam service shall be conducted at a pressure which does not exceed the set pressure by more than 3% or 2 psi (13.8 kPa), whichever is greater.

Page 333

(b) Capacity certification tests of pressure relief valves with set pressures of 15 psig and higher for air, gas, or steam service other than main steam service shall be conducted at a pressure which does not exceed the set pressure by more than 10% or 3 psi, whichever is greater.

(c) Capacity certification tests for air or gas service with set pressures of 3 psig up to but not including 15 psig shall be conducted in accordance with the requirements of NC-7731 through NC-7734. When tests are performed in accordance with NC-7734, the capacity shall be determined at no more than 2 psi above the actual set pressure.

[98]

[98]

NC-7731.4 Blowdown

(a) Valves set at or above 15 psig, having an adjustable blowdown construction, shall be adjusted prior to capacity certification testing so that the blowdown does not exceed 5% of the set pressure.

(b) Valves set below 15 psig, having adjustable blowdown construction, shall be adjusted prior to capacity certification testing so that blowdown does not exceed 3 psi and shall not be less than 0.5 psi.

[98]

NC-7731.5 Drawings.

Prior to capacity certification tests, the Certificate Holder shall submit drawings showing the valve construction to the Authorized Observer. The Authorized Observer shall submit the drawings and all test results to the ASME designee for review and acceptance.

NC-7731.6 Design Changes.

When changes are made in the design of a pressure relief valve which affect the flow path, lift, or performance characteristics, new tests shall be performed in accordance with this Subarticle.

NC-7732 Flow Model Test Method - Pilot or Power Operated Valves

NC-7732.1 Flow Capacity.

When test facility limitations make it impossible to perform capacity tests of the full-scale pressure relief valves, flow models of three different sizes may be utilized as a basis for capacity certification. Such flow models shall be sized consistent with the capabilities of the accepted test laboratory where the tests will be conducted and shall accurately model those features, such as orifice size, valve lift, and internal flow configuration, which affect flow capacity. The test models need not be functional pressure relief valves, provided that other tests are conducted to demonstrate proper function of the valve design as prescribed in NC-7732.2. The relieving capacity of valve designs certified by use of flow models shall be established by the coefficient of discharge method similar to that outlined in NC-7734. The certified relieving capacity of all sizes and pressures of a given design for which the value of K has been established, based on flow model tests in accordance with the method of NC-7734, shall not exceed the value calculated by the appropriate formula in NC-7734.2 multiplied by the coefficient K .

NC-7732.2 Demonstration of Function.

The function of three valves of the design to be certified shall be demonstrated by tests. Such tests may be performed in conjunction with the capacity certification tests outlined above or as separate tests using production valves. The purpose of these tests is to demonstrate to the satisfaction of an ASME designee that the valve will open at set pressure within the required opening pressure tolerance, will achieve full lift, and will reclose within required blowdown. If required by test facility limitations, these tests may be conducted at reduced flow capabilities. Measurement of valve blowdown may not be possible.

[98]

NC-7733 Slope Method

(a) For pressure relief valves of a specific design, four valves of each combination inlet size and orifice size shall be tested. These four valves shall be set at pressures that will cover the appropriate range of pressures for which the valves are to be used or within the range of the authorized test facility.

(b) The instantaneous slope of each test point shall be calculated and averaged, where slope is defined as follows.

(1) For valves with set pressures of 15 psig and greater, slope is defined as the measured capacity divided by the absolute inlet pressure.

(2) For valves with set pressures of 3 psig up to but not including 15 psig, slope is defined as the measured capacity divided by the quantity,

$$F[(P)(P - P_o)]^{1/2}$$

where

$$F = \sqrt{\left(\frac{k}{k-1}\right) (r^{2/k}) \left[\frac{1 - (r)^{\frac{k-1}{k}}}{1-r} \right]}$$

P = inlet pressure, psi

P_o = discharge pressure, psi

Page 334

k = ratio of specific heats, C_v/C_p

r = pressure ratio, P_o/P

(c) If any of the experimentally determined slopes fall outside of a range of $\pm 5\%$ of the average slope, the unacceptable valves shall be replaced by two valves of the same size and set pressure. Following the test of these valves, a new average slope shall be determined, excluding the replaced valve test results. If any individual slope is now outside of the $\pm 5\%$ range, then the tests shall be considered unsatisfactory and shall be cause for the ASME designee to refuse certification of the particular valve design.

(d) For valves with set pressures of 15 psig and greater, the certified capacity shall be 90% of the average slope multiplied by the flow rating pressure, psia.

(e) For valves with set pressures of 3 psig up to but not including 15 psig, the certified capacity shall be 90% of the average slope multiplied by the quantity,

$$F[(P)(P - P_o)]^{1/2}$$

(f) In addition, demonstration of function tests shall be conducted as prescribed in NC-7732.2.
[98]

NC-7734 Coefficient of Discharge Method

A coefficient K may be established for a specific pressure relief valve design according to the procedure given in the following subparagraphs.

NC-7734.1 Number of Valves to Be Tested.

For each design, at least three valves for each of three different sizes shall be submitted for test. Each valve of a given size shall be set at a different pressure.

size shall be set at a different pressure.

[98]

NC-7734.2 Establishment of Coefficient of Discharge

(a) Tests shall be made on each pressure relief valve to determine its lift, opening and blowdown pressures, and capacity in terms of the fluid used in the test. A coefficient of discharge K_D shall be established for each test run as follows:

$$K_D = \frac{\text{Actual Flow}}{\text{Theoretical Flow}} = \text{Coefficient of Discharge}$$

where Actual Flow is determined quantitatively by test, and Theoretical Flow is calculated by the following formula.

(1) For valves with set pressures of 15 psig and greater. For test with dry saturated steam:

$$W_T = 51.5AP$$

For pressures over 1500 psig (10 MPa) and up to 3200 psig (20 MPa), the value of W_T calculated by the above equation, shall be corrected by being multiplied by the following factor:

$$\frac{(0.1906P - 1000)}{(0.2292P - 1061)}$$

For test with air:

$$W_T = 356AP\sqrt{M/T}$$

For test with gas:

$$W_T = CAP\sqrt{M/ZT}$$

where

W_T	= Theoretical Flow, lb/hr
C	= constant for gas or vapor which is a function of the ratio of specific heats, k
k	= C_p/C_v , ratio of specific heats (see Fig. XVIII-1110-1)
A	= actual discharge area through the valve at developed lift, sq in.
P	= (set pressure $\times$ 1.03) plus atmospheric pressure, psia, or set pressure plus 2 psi plus atmospheric pressure, whichever is greater, for test pressures determined by NC-7731.3(a) = (set pressure $\times$ 1.10) plus atmospheric pressure, psia, or set pressure plus 3 psi plus atmospheric pressure, whichever is greater, for test pressures determined by NC-7731.3(b)
M	= molecular weight
T	= absolute temperature at inlet, $^{\circ}\text{F} + 460$
Z	= compressibility factor corresponding to P and T

The average of the coefficients of discharge K_D of the tests required shall be multiplied by 0.90, and their product shall be taken as the coefficient K of that design. The coefficient of the design shall not be greater than 0.876 (the product of 0.9×0.975).

(2) For valves with set pressures of 3 psig up to but not including 15 psig. The following formula may be used for other than saturated steam flow:

$$W = 735FA \left[\frac{MP(P - P_o)}{T} \right]^{1/2}$$

$$Q = 279,000FA \left[\frac{P(P - P_o)}{MT} \right]^{1/2}$$

[98]

FIG. NC-7734.2(a)-1 VALUES OF F FOR NONCHOKING FLOW

where

$$F = \sqrt{\left(\frac{k}{k-1}\right) (r^{2/k}) \left[\frac{1 - (r)^{\frac{k-1}{k}}}{1-r} \right]}$$

or is obtained from Fig. NC-7754.2(a)-1.

A	= flow area, sq in.
M	= molecular weight
P	= inlet pressure, psi
P_o	= discharge pressure, psi
T	= temperature, deg. Rankin
k	= ratio of specific heats, c_p/c_v
r	= pressure ratio, P_o/P
Q	= cu ft/hr at 14.7 psi and 60°F
W	= lb/hr

The average of the coefficients of discharge K_d of the tests required shall be multiplied by 0.90 and their product shall be the coefficient K of that design. The coefficient of the design shall not be greater than 0.876 (the product of 0.90×0.975).

(b) If any of the experimentally determined coefficients fall outside of a range of $\pm 5\%$ of the average coefficient, the unacceptable valves shall be replaced by two valves of the same size and set pressure. Following the test of these valves, a new average coefficient shall be determined, excluding the replaced valve test results. If any individual coefficient is now outside of the $\pm 5\%$ range, then the test shall be considered unsatisfactory and shall be cause for the ASME designee to refuse certification of the particular valve design.

[98]

NC-7734.3 Calculation of Certified Capacity

(a) The certified capacity of all sizes and pressures of a given design, for which the value of K has been established under the provisions of NC-7734.2 and which are manufactured subsequently, shall not exceed the value calculated by the appropriate formula multiplied by the coefficient K .

(b) The coefficient shall not be applied to valves whose beta ratio (the ratio of valve throat and inlet diameter) lies outside the range of 0.15 to 0.75, unless tests have demonstrated that individual coefficients of discharge, K_d , for valves of the extreme ends of a larger range is within $\pm 5\%$ of the average coefficient, K . For designs where lift is used to determine the flow area, all valves shall have the same nominal lift-to-seat diameter ratio (L/D).

NC-7734.4 Demonstration of Function.

Tests shall be conducted as prescribed in NC-7732.2.

NC-7735 Single Valve Method

NC-7735.1 Valve Capacity Within Test Facility Limits

(a) When a single valve is to be capacity tested, the certified capacity may be based on three separate tests associated with each set pressure for which capacity certification is required.

(b) The certified capacity associated with each set pressure shall not exceed 90% of the average capacity established by the tests. Failure of the individual test capacities to fall within $\pm 5\%$ of the average capacity associated with each set pressure shall be cause for rejection of the test. The reason for the failure shall be determined and the test repeated.

(c) Should additional valves of the same design be constructed at a later date, the results of the tests on the original valve may be included as applicable to the particular test method selected.

NC-7735.2 Valve Capacity in Excess of Test Facility Limits.

For valves whose capacity exceeds that of the test facility, the certified capacity may be based on a flow coefficient K (NC-7734.2) determined from either blocked open flow tests or flow model tests, provided the orifice area is such that choked flow conditions are obtained. The certified capacity shall be calculated as directed in NC-7734.3.

NC-7735.3 Valve Demonstration of Function.

The proper operation of the valve shall be demonstrated as prescribed in NC-7732.2.

NC-7736 Proration of Capacity

(a) The capacity of a pressure relief valve applied to a system may be prorated to an overpressure greater than the overpressure for which the valve design is certified. This overpressure shall be within the allowable limits of the system.

(b) Depending on the method used for the initial capacity certification:

(1) the prorated capacity shall be 90% of the average slope determined in NC-7733 multiplied by the prorated relieving pressure (psia), or;

(2) the prorated capacity shall be calculated using the appropriate formula from NC-7734.2 (where P is the prorated relieving pressure (psia) multiplied by the coefficient K .

NC-7737 Capacity Conversions

The relieving capacity of pressure relief valves for fluids other than the fluid used for certification shall be determined by the method of conversion given in Appendix XVIII-1000, except that valves for steam service shall be tested on steam.

NC-7738 Laboratory Acceptance of Pressure Relieving Capacity Tests

Tests shall be conducted at a place where the testing facilities, methods, procedures, and Authorized Observer (person

supervising the tests) meet the applicable requirements of ASME PTC 25-1994, Pressure Relief Devices. The tests shall be made under the supervision of and certified by an Authorized Observer. The testing facilities, methods, procedures, and qualifications of the Authorized Observer shall be subject to the acceptance of the ASME Boiler and Pressure Vessel Committee on recommendation of an ASME designee. Acceptance of the testing facility is subject to review within each 5 year period. Capacity test data shall be submitted to the ASME designee for review and acceptance.¹⁹

19 Valve capacities are published in "Pressure Relief Device Certifications." This publication may be obtained from the National Board of Boiler and Pressure Vessel Inspectors, 1055 Crupper Avenue, Columbus, OH 43229.

NC-7739 Laboratory Acceptance of Demonstration of Function Tests

The NV Certificate Holder shall assure that the tests are conducted at a place where the testing facilities, methods, and procedures provide for sufficient testing

Page 337

capacity and range of fluid properties so that the testing requirements of NC-7732.2 are met.

NC-7740 CAPACITY CERTIFICATION OF PRESSURE RELIEF VALVES - INCOMPRESSIBLE FLUIDS

NC-7741 General Requirements

NC-7741.1 Capacity Certification.

Capacity certification procedures shall be as required in NC-7742 through NC-7745.

NC-7741.2 Test Medium.

The test medium to be used for capacity certification shall be water at a temperature between 40°F (4°C) and 125°F (52°C).

NC-7741.3 Test Pressure.

Tests shall be conducted at pressures which do not exceed the set pressure by more than 10% or 3 psi (20.6 kPa), whichever is greater.

NC-7741.4 Blowdown.

Blowdown shall be recorded at time of the test.

NC-7741.5 Drawings.

Prior to capacity certification tests, the Certificate Holder shall submit drawings showing the valve construction to the Authorized Observer. The Authorized Observer shall submit the drawings and all test results to the ASME designee for review and acceptance.

NC-7741.6 Design Changes.

When changes are made in the design of a pressure relief valve in such a manner as to affect the flow path, lift, or performance characteristics of the valve, new tests in accordance with this Subarticle shall be performed.

NC-7742 Slope Method

Four valves of each combination of pipe size and orifice size shall be tested. These four valves shall be set at pressures which cover the appropriate range of pressures for which the valves are to be used or within the range of the test facility. The instantaneous slope of each test point shall be calculated and averaged, where slope is defined as the measured capacity divided by the square root of the difference between the flow rating pressure and the valve discharge pressure. If any of the experimentally determined slopes fall outside of a range of $\pm 5\%$ of the average slope, the unacceptable valves shall be replaced by two valves of the same size and set pressure. Following the test of these valves, a new average slope

shall be determined, excluding the replaced valve test results. If any individual slope is now outside of the $\pm 5\%$ range, then the tests shall be considered unsatisfactory and shall be cause for the ASME designee to refuse certification of the particular valve design. The certified capacity shall be 90% of the average slope multiplied by the square root of the difference between the flow rating pressure and the valve discharge pressure.

NC-7743 Coefficient of Discharge Method

Instead of individual capacity tests or the capacity curve method, a coefficient K may be established for a specific pressure relief valve design in accordance with the following subparagraphs.

NC-7743.1 Number of Valves to Be Tested.

For each design, three valves for each of three different sizes shall be tested, for a total of nine valves. Each valve of a given size shall be set at a different pressure.

NC-7743.2 Establishment of Coefficient of Discharge

(a) Tests shall be made on each relief valve to determine its lift, opening and closing pressures, and actual capacity in terms of pounds of water per hour. A coefficient of discharge K_D shall be established for each test run as follows:

$$K_D = \frac{\text{Actual Flow}}{\text{Theoretical Flow}} = \text{Coefficient of Discharge}$$

where Actual Flow is determined quantitatively by test and Theoretical Flow is calculated by the following formula. For test with water:

$$W_t = 2407A \sqrt{(P - P_d)w}$$

where

W_t	= Theoretical Flow, lb/hr
A	= actual minimum discharge area through the valve at developed lift, sq in.
P	= (set pressure $\times 1.10$) plus atmospheric pressure, psia, or set pressure plus 3 psi plus atmospheric pressure, whichever is greater
P_d	= pressure at discharge from valve, psia
w	= density of water at valve inlet conditions, lb/cu ft

The average of the coefficients of discharge K_D of the tests shall be multiplied by 0.90 and the product shall be taken as the coefficient K of the design. The coefficient of the design shall not be greater than 0.876 (the product of 0.9×0.975).

Page 338

(b) If any of the experimentally determined coefficients fall outside of a range of $\pm 5\%$ of the average coefficient, the unacceptable valves shall be replaced by two valves of the same size and set pressure. Following the test of these valves, a new average coefficient shall be determined, excluding the replaced valve test results. If any individual coefficient is

now outside of the $\pm 5\%$ range, then the test shall be considered unsatisfactory and shall be cause for the ASME designee to refuse certification of the particular valve design.

NC-7743.3 Calculation of Certified Capacity

(a) The certified capacity of all sizes and pressures of a given design for which the value of K has been established under the provisions of NC-7744.2 shall not exceed the value calculated by the theoretical formula above multiplied by the coefficient K .

(b) The coefficient shall not be applied to valves whose beta ratio (the ratio of valve throat and inlet diameter) lies outside the range of 0.15 to 0.75, unless tests have demonstrated that individual coefficients of discharge, K_d , for valves of the extreme ends of a larger range is within $\pm 5\%$ of the average coefficient, K . For designs where lift is used to determine the flow area, all valves shall have the same nominal lift-to-seat diameter ratio (L/D).

NC-7744 Single Valve Method

Where a single valve at a single pressure is to be capacity tested, the capacity rating may be based on three separate tests of the single valve at the specified set pressure. The certified capacity rating of the valve shall not exceed 90% of the average capacity established by the tests. Failure of the individual test capacities to fall within $\pm 5\%$ of the average capacity may be cause for rejection of the test. The reason for the failure shall be determined and the test repeated.

Should additional valves of the same design be constructed at a later date, the results of the tests on the original valve may be included as applicable to the particular test method selected.

NC-7745 Laboratory Acceptance of Pressure Relieving Capacity Tests

Tests shall be conducted at a place where the testing facilities, methods, procedures, and Authorized Observer (person supervising the tests) meet the applicable requirements of ASME PTC 25-1994, Pressure Relief Devices. The tests shall be made under the supervision of and certified by an Authorized Observer. The testing facilities, methods, procedures, and qualifications of the Authorized Observer shall be subject to the acceptance of the ASME Boiler and Pressure Vessel Committee on recommendation of an ASME designee. Acceptance of the testing facility is subject to review within each 5 year period. Capacity test data shall be submitted to the ASME designee for review and acceptance.¹⁷

NC-7746 Proration of Capacity

(a) The capacity of a pressure relief valve applied to a system may be prorated to an overpressure greater than the overpressure for which the valve design is certified. This overpressure shall be within the allowable limits of the system.

(b) Depending on the method used for the initial capacity certification:

(1) the prorated capacity shall be 90% of the average slope determined in NC-7742 multiplied by the prorated relieving pressure (psia), or;

(2) the prorated capacity shall be calculated using the appropriate formula from NC-7743.2 [where P is the prorated relieving pressure (psia) multiplied by the coefficient K].

NC-7747 Capacity Conversion

The rated pressure relieving capacity of pressure relief valves for liquids other than the liquids used for certification shall be determined by the method of conversion given in Appendix XVIII-1000. This conversion is not valid for liquid flashing valve operating conditions.

NC-7750 CAPACITY CERTIFICATION OF VACUUM RELIEF VALVES

NC-7751 General Requirements

NC-7751.1 Capacity Certification.

Capacity certification procedures shall be as required in NC-7752 through NC-7755.

NC-7751.2 Test Media.

Capacity certification tests for vacuum relief valves for air and gas service shall be conducted with dry steam, air, or gas. For steam test purposes the limits of 98% minimum quality and 20°F maximum superheat shall apply. Capacity shall be corrected to dry saturated condition from these limits.

NC-7751.3 Test Method and Pressure.

Capacity tests may be conducted by pressurizing the valve instead of using a vacuum, provided the inlet conditions of

Page 339

the valve (not the vessel) are known and the inlet pressure is not greater than 5 psi (35 kPa), and the direction of flow through the valve is the same on pressure as is experienced on vacuum. Tests shall be conducted at twice the set pressure or 1 psi (7 kPa), whichever is greater.

NC-7751.4 Blowdown.

Blowdown shall be recorded at the time of the test.

NC-7751.5 Drawings.

Prior to a test, the Certificate Holder shall submit drawings showing the valve construction to the Authorized Observer. The Authorized Observer shall submit the drawings and test results to the ASME designee for review and acceptance.

NC-7751.6 Design Change.

When changes are made in the design of a vacuum relief valve in such a manner as to affect the flow path, lift, or performance characteristics of the valve, new tests in accordance with this Article shall be performed.

NC-7752 Single Valve Method

(a) When a single valve at a single pressure is to be capacity tested, the capacity rating may be based on three separate and distinct tests of the single valve at the specified set pressure. The certified capacity rating of the valve shall not exceed 90% of the average capacity established by the tests. Failure of the individual test capacities to fall within $\pm 5\%$ of the average capacity shall be cause for rejection of the test. The reason for the failure shall be determined and the test repeated.

(b) Should additional valves of the same design be constructed at a later date, the results of the test on the original valve may be included as applicable to the particular test method selected.

NC-7753 Slope Method

Four valves of each combination of pipe size and orifice size shall be tested. These four valves shall be set at pressures which cover the appropriate range of pressures for which the valves are to be used or set within the range of the test facility. The slope of each test shall be calculated and averaged, where slope is defined as the measured capacity divided by the quantity, $F[(P)(P - P_o)]^{1/2}$

where

$$F = \sqrt{\left(\frac{k}{k-1}\right) (r^{2/k}) \left[\frac{1 - (r)^{\frac{k-1}{k}}}{1-r} \right]}$$

P	= inlet pressure, psi
P_o	= discharge pressure, psi
k	= ratio of specific heats, c_v/c_p
r	= pressure ratio, P_o/P

If any of the experimentally determined slopes fall outside of a range of $\pm 5\%$ of the average slope, the unacceptable valves shall be replaced by two valves of the same size and set pressure. Following the test of these valves, a new average slope shall be determined, excluding the replaced valve test results. If any individual slope is now outside of the $\pm 5\%$ range, then the tests shall be considered unsatisfactory and shall be cause for the ASME designee to refuse certification of the particular valve design. The certified capacity shall be 90% of the average slope multiplied by the quantity, $F[(P)(P - P_o)]^{1/2}$

NC-7754 Coefficient of Discharge Method

A coefficient K may be established for a specific vacuum relief valve design in accordance with NC-7754.1 and NC-7754.2.

NC-7754.1 Number of Valves to Be Tested.

For each design, three valves of three different sizes, a total of nine valves, shall be tested. Each valve of a given size shall be set at a different pressure.

NC-7754.2 Establishment of Coefficient of Discharge

(a) Tests shall be made on each relief valve to determine its lift, opening and closing pressures, and actual capacity. A coefficient of discharge K_D shall be established for each run as follows:

$$K_D = \frac{\text{Actual Flow}}{\text{Theoretical Flow}} = \text{Coefficient of Discharge}$$

where Actual Flow is determined quantitatively by test, and Theoretical Flow is calculated from the appropriate equation for the test fluid. The following formula may be used for other than saturated steam flow:

Page 340

$$W = 735FA \left[\frac{MP(P - P_o)}{T} \right]^{1/2}$$

$$Q = 279,000FA \left[\frac{P(P - P_o)}{MT} \right]^{1/2}$$

where

$$F = \sqrt{\left(\frac{k}{k-1}\right) (r^{2/k}) \left[\frac{1 - (r)^{\frac{k-1}{k}}}{1-r} \right]}$$

or is obtained from Fig. NC-7754.2(a)-1.

A	= flow area, sq in.
M	= molecular weight
P	= inlet pressure, psi
P_o	= discharge pressure, psi
T	= temperature, deg. Rankin
k	= ratio of specific heats, c_v/c_p
r	= pressure ratio, P_o/P
Q	= cu ft/hr at 14.7 psi and 60°F
W	= lb/hr

The average of the coefficients of discharge K_D of the tests required shall be multiplied by 0.90 and their product shall be the coefficient K of that design. The coefficient of the design shall not be greater than 0.876 (the product of 0.9×0.975).

(b) If any of the experimentally determined coefficients fall outside of a range of $\pm 5\%$ of the average coefficient, the unacceptable valves shall be replaced by two valves of the same size and set pressure. Following the test of these valves, a new average coefficient shall be determined, excluding the replaced valve test results. If any individual coefficient is now outside of the $\pm 5\%$ range, then the test shall be considered unsatisfactory and shall be cause for the ASME designee to refuse certification of the particular valve design.

NC-7754.3 Calculation of Relieving Capacity

(a) The certified relieving capacity of all sizes and pressures of a given design, for which the value of K has been established, shall be calculated by the appropriate formula given above multiplied by the coefficient K . Values obtained from pressurized tests may be converted to equivalent vacuum from the above equation.

(b) The coefficient shall not be applied to valves whose beta ratio (the ratio of valve throat and inlet diameter) lies

outside the range of 0.15 to 0.75, unless tests have demonstrated that individual coefficients of discharge, K_d , for valves of the extreme ends of a larger range is within $\pm 5\%$ of the average coefficient, K . For designs where lift is used to determine the flow area, all valves shall have the same nominal lift-to-seat diameter ratio (L/D).

NC-7755 Laboratory Acceptance of Relieving Capacity Tests

Tests shall be conducted at a place where the testing facilities, methods, procedures, and person supervising the tests (Authorized Observer) meet the applicable requirements of ASME PTC 25-1994, Pressure Relief Devices. The tests shall be made under the supervision of and certified by an Authorized Observer. The testing facilities, methods, procedures, and qualifications of the Authorized Observer shall be subject to the acceptance of the ASME Boiler and Pressure Vessel Committee on recommendation of an ASME designee. Acceptance of the testing facility is subject to review within each 5 year period. Capacity test data shall be submitted to the ASME designee for review and acceptance.¹⁷

NC-7760 CAPACITY DETERMINATION OF RUPTURE DISK DEVICES

NC-7761 General Requirements

NC-7761.1 Test Media

(a) Capacity tests of rupture disk devices for steam service shall be conducted with dry saturated steam. For test purposes, the limits of 98% minimum quality and 20°F (-7°C) maximum superheat shall apply. Capacity shall be corrected to the dry saturated condition from within these limits.

(b) Capacity tests for rupture disk devices for air and gas service shall be conducted with air, gas, or dry saturated steam.

NC-7761.2 Test Pressure

(a) Capacity tests of rupture disk devices shall be conducted at a pressure not exceeding 110% of the stamped burst pressure.

(b) Capacity tests of rupture disk devices used at the inlet side of pressure relief valves shall be conducted at a pressure not exceeding 110% of the valve set pressure.

FIG. NC-7754.2(a)-1 VALUES OF F FOR NONCHOKING FLOW

FIG. NC-7754.2(a)-1 VALUES OF F FOR NONCHOKING FLOW

NC-7762 Capacity Determination of Rupture Disk Devices in Combination With Pressure Relief Valves

NC-7762.1 Capacity Determination Without Flow Test

(a) The rated capacity of the combination of a pressure relief valve when installed with a rupture disk device at the inlet side of the valve shall not exceed 80% of the certified capacity of the valve. Alternatively, the capacity of such a combination shall be established in accordance with NC-7762.2.

(b) The rated capacity of the combination of a pressure relief valve when installed with a rupture disk device at the outlet of the valve shall be the certified capacity of the valve.

NC-7762.2 Capacity of Pressure Relief Valves in Combination With a Rupture Disk Device at the Inlet.

For each combination of pressure relief valve design and rupture disk device design, the Certificate Holder or the rupture disk device manufacturer shall have the capacity of the combination determined as prescribed in (a) and (b) below.

(a) The Certificate Holder or the rupture disk device manufacturer shall submit for tests the smallest rupture disk device size with the equivalent size of pressure relief valve that is intended to be used as a combination device. The pressure relief valve to be tested shall have the largest orifice used in the particular inlet size.

(b) Tests shall be performed in accordance with the requirements of (1) through (5) below. The rupture disk device and pressure relief valve combination to be tested shall be arranged to duplicate the combination assembly design.

(1) The test shall be made using the minimum burst pressure of the rupture disk device design that is to be used in combination with the pressure relief valve design. The stamped bursting pressure shall be between 90-100% of the stamped set pressure of the valve.

(2) The test procedure to be used shall be as follows:

Page 342

(a) The pressure relief valve by itself shall be tested for capacity without the rupture disk device at a pressure 10% above the valve set pressure.

(b) The rupture disk device shall then be installed in front of the pressure relief valve and the disk burst to operate the valve. The capacity test shall be performed on the combination at 10% above the valve set pressure duplicating the test of (a) above.

(3) The tests shall be repeated with two additional rupture disks of the same nominal rating for a total of three rupture disks to be tested with the single valve. The results of the test capacity shall fall within a range of 10% of the average capacity of the three tests. Failure to meet this requirement shall be cause to require retest for determination of cause of the discrepancies.

(4) From the results of the tests, a Combination Capacity Factor shall be determined. The Combination Capacity Factor is the ratio of the average capacity which is determined by the combination tests to the capacity which is determined by the test of (a) above. The Combination Capacity Factor shall be used as a multiplier to the certified capacity of the pressure relief valve in all sizes of the design, except when a different factor has been established for larger sizes and other pressures in accordance with NC-7762.3. The value of the Combination Capacity Factor shall not be greater than one. The Combination Capacity Factor shall apply only to combinations of the same design and manufacture of the pressure relief valve and the same design and manufacture of the rupture disk device as those tested.

(5) The test laboratory shall submit the test results to ASME designee for acceptance of the Combination Capacity Factor.

NC-7762.3 Optional Testing of Rupture Disk Devices and Pressure Relief Valves

(a) If desired, a Certificate Holder or a rupture disk manufacturer may conduct tests in the same manner as given in NC-7762.2 using the next two larger sizes of the same design of rupture disk device and pressure relief valve to determine a Combination Capacity Factor applicable to larger sizes. If a greater Combination Capacity Factor is established and can be approved, it may be used for all larger sizes of the combination, but the Factor shall not be greater than one.

(b) If desired, additional tests may be conducted at higher pressures in accordance with NC-7762.2 to establish a maximum Combination Capacity Factor to be used at all pressures higher than the highest tested, but the Factor shall not be greater than one.

NC-7763 Capacity of Rupture Disk Devices

NC-7763.1 Calculated Capacity

(a) The calculated capacity of a rupture disk device shall not exceed a value based on the applicable theoretical formula (Appendix XVIII) for the various media multiplied by a value for K of 0.62. The area A in the theoretical formula shall be the minimum net flow area existing after disk burst.

(b) The minimum net flow area is the calculated net area after a complete burst of the disk, with appropriate allowance for any structural members which may reduce the net flow area through the rupture disk device. The net flow area for sizing purposes shall not exceed the nominal pipe size area of the rupture disk device.

NC-7763.2 Tested Capacity.

A manufacturer may have the capacity of a given rupture disk device design approved for K_D in general accordance with the procedures of NC-7730, as applicable.

NC-7764 Laboratory Acceptance of Pressure Relieving Capacity Tests

Tests shall be conducted at a place where the testing facilities, methods, procedures, and Authorized Observer (person supervising the tests) meet the applicable requirements of ASME PTC 25-1994, Pressure Relief Devices. The tests shall be made under the supervision of and certified by an Authorized Observer. The testing facilities, methods, procedures, and qualifications of the Authorized Observer shall be subject to the acceptance of the ASME Boiler and Pressure Vessel Committee on recommendation of an ASME designee. Acceptance of the testing facility is subject to review within each 5 year period. Capacity test data shall be submitted to the ASME designee for review and acceptance.¹⁷

NC-7800 MARKING, STAMPING, AND DATA REPORTS

NC-7810 PRESSURE AND VACUUM RELIEF VALVES

NC-7811 Marking and Stamping

Each pressure relief valve shall be plainly marked by the Certificate Holder with the required data below in such a way that the marking will not be obliterated in service. The data shall be in characters not less than $\frac{3}{32}$ in. high. The marking shall be placed on the valve or on a nameplate securely fastened to the valve. The Code NV Symbol shall be stamped on the valve or

Page 343

nameplate, but the other required data may be stamped, etched, impressed, or cast. The marking shall include the following:

- (a) name, or an acceptable abbreviation, of the Certificate Holder
- (b) Certificate Holder's design or type number
- (c) size _____ (NPS, the nominal pipe size) of the valve inlet
- (d) set pressure _____ psi
- (e) certified capacity and overpressure in percent or psi in accordance with NC-7700

Pressure Relief Valves:

- lb/hr of saturated steam for valves certified on steam, or
- scfm (standard cubic feet per minute) at 60°F and 14.7 psia of air for valves certified on air or gas, or
- gal/min of water at 70°F for valves certified on water

Vacuum Relief Valves:

- scfh (standard cubic feet per hour) at 60°F and 14.7 psi
- (f) applicable official Code Symbol Stamp, as shown in Table NCA-8100-1

In addition to the above, each pressure relief valve shall have a separate nameplate attached to the component that includes the marking requirements of NCA-8220 and NC-3593.2.

NC-7812 Report Form for Pressure and Vacuum Relief Valves

A Data Report Form NV-1 shall be filled out and signed by the Certificate Holder and signed by the Inspector for each pressure and vacuum relief valve stamped with the Code NV Symbol.

NC-7820 RUPTURE DISK DEVICES

NC-7821 Rupture Disks

Every rupture disk shall be plainly marked by the manufacturer in such a way that the marking will not be obliterated in service. The rupture disk marking may be placed on the flange of the rupture disk or on a metal tab permanently attached thereto.²⁰ The marking shall include the following:

20 In lieu of marking all of the listed items on the flange or tab of each rupture disk, the marking may consist of a manufacturer's coding number sufficient to identify each rupture disk with a certificate or tab which includes the required information and is supplied with each lot of rupture disks.

- (a) name or identifying trademark of the manufacturer
- (b) manufacturer's design or type number
- (c) lot number
- (d) size _____ in.
- (e) stamped bursting pressure _____ psi
- (f) specified disk temperature _____ °F
- (g) capacity _____ lb/hr of saturated steam/hr or standard cu ft/min of air (60°F and 14.7 psia)
- (h) year built

NC-7822 Disk Holders (If Used)

Rupture disk holders shall be marked with the following:

- (a) name or identifying trademark of the manufacturer
- (b) manufacturer's design or type number
- (c) size _____ in.
- (d) year built
- (e) serial number

NC-7830 PRESSURE RELIEF VALVE IN COMBINATION WITH RUPTURE DISK DEVICES

NC-7831 Marking When Capacity Is Approved in Accordance With NC-7762.1

The marking shall be placed either on the valve or the rupture disk holder or on a plate or plates securely fastened to the valve or the rupture disk holder. The marking shall include a Combination Capacity Factor of 0.8.

NC-7832 Marking When Capacity Is Approved in Accordance With NC-7762.2

The following marking shall be in addition to the marking required by NC-7811 and NC-7822. The marking shall be placed on the valve or the rupture disk holder or on a plate or plates securely fastened to the valve or the rupture disk holder. The marking shall include the following:

- (a) name of the Certificate Holder
- (b) design or type or serial number of valve
- (c) name of manufacturer of rupture disk device

(d) design or type designation of rupture disk device

(e) approved Combination Capacity Factor

Page 344

NC-7840 CERTIFICATE OF AUTHORIZATION TO USE CODE SYMBOL STAMP

Each pressure and vacuum relief valve within the scope of this Article shall be constructed by a Certificate Holder possessing a Code NV Symbol Stamp and a valid Certificate of Authorization. Pressure and vacuum relief valves shall have the Code NV Symbol applied in accordance with the rules of NC-8100.

area	square meter	m ²	
volume	cubic meter	m ³	liter (L) for liquid only (use without prefix other than in milliliter, mL)
time	second	s	minute (min), hour (h), day (d), week, and year
Periodic and Related Phenomena			
frequency	hertz	Hz	revolutions per second (r/s)
rotational frequency	revolutions per second	s ⁻¹	revolutions per minute (r/m)
Mechanics			
mass	kilogram	kg	
density	kilogram per cubic meter	kg/m ³	
moment of inertia	kilogram · meter ²	kg · m ²	
force	newton	N	
moment of force (torque)	newton-meter	N · m	
pressure and stress	pascal	Pa	(pascal = newton per square meter)
energy, work	joule	J	kilowatt-hour (kW · h)
power	watt	W	
impact strength	joule	J	
section modulus	meter ³	m ³	
moment of section (second moment of area)	meter ⁴	m ⁴	
fracture toughness	Pa · $\sqrt{m}$		
Heat			
temperature — thermodynamic [Note (2)]	kelvin	K	degree Celsius (°C)
temperature — other than thermodynamic	degree Celsius	°C	kelvin (K)
linear expansion coefficient	meter per meter-kelvin	K ⁻¹	°C ⁻¹
quantity of heat	joule	J	
heat flow rate	watt	W	
thermal conductivity	watt per meter-kelvin	W/(m · K)	W/(m · °C)
thermal diffusivity	square meter per second	m ² /s	
specific heat capacity	joule per kilogram-kelvin	J/(kg · K)	J/(kg · °C)
Electricity and Magnetism			
electric current	ampere	A	
electric potential	volt	V	
current density	ampere per meter ²	A/m ²	
magnetic field strength	ampere per meter	A/m	

NOTES:

- (1) Conversion factors between SI units and U.S. customary are given in SI-1, "ASME Orientation and Guide for Use of SI (Metric) Units," and ASTM E 380.
- (2) Preferred use for temperature and temperature interval is degrees Celsius (°C), except for thermodynamic and cryogenic work where kelvins may be more suitable. For temperature interval, 1 K = 1°C exactly.

NOTES:

- (1) Care should be taken when converting formulas or equations that contain constant terms or factors. The value of these terms must be understood and may also require conversion.
- (2)(a) Relationships that are exact in terms of the base units are followed by a single asterisk.
- (b) The factors are written as a number greater than 1 and less than 10 with 6 or less decimal places. The number is followed by the letter E (for exponent), a plus or minus symbol, and two digits which indicate the power of 10 by which the number must be multiplied to obtain the correct value. For example: 3.523 907 E-02 is $3.523\ 907 \times 10^{-2}$ or 0.035 239 07.

**IMPORTANT INFORMATION ON THE 1998 BOILER AND PRESSURE VESSEL CODE
ADDENDA DISTRIBUTION SCHEDULE**

There is a change in the way the Addenda to the 1998 Edition of the ASME Boiler and Pressure Vessel Code are distributed. The 1998 Edition, published July 1, 1998, incorporates the 1998 Addenda revisions, additions, or deletions. There will be no separate 1998 Addenda issued in a replacement page format. Two additional Addenda to the 1998 Edition, in the form of replacement pages, will be issued on July 1, 1999 and July 1, 2000.

The Summary of Changes published with the 1998 Edition lists and describes the revisions that are part of the 1998 Addenda. These changes are identified with a margin note, **98**, denoting the affected area.

The Addenda for 1999 and 2000 will also have a Summary of Changes and identifiers printed on the replacement pages. The revisions, additions, or deletions will be incorporated directly into the affected pages. It is advisable to retain the title sheets and all replaced pages for reference.

The effective dates for Code Editions and Addenda are described in the Foreword.

This code or standard was developed under procedures accredited as meeting the criteria for American National Standards.

This code or standard was developed under procedures accredited as meeting the criteria for American National Standards. The Standards Committee that approved the code or standard was balanced to assure that individuals from competent and concerned interests have had an opportunity to participate. The proposed code or standard was made available for public review and comment which provides an opportunity for additional public input from industry, academia, regulatory agencies, and the public-at-large.

ASME does not "approve," "rate," or "endorse" any item, construction, proprietary device, or activity.

ASME does not take any position with respect to the validity of any patent rights asserted in connection with any items mentioned in this document, and does not undertake to insure anyone utilizing a standard against liability for infringement of any applicable Letters Patent, nor assume any such liability. Users of a code or standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, is entirely their own responsibility.

Participation by federal agency representative(s) or person(s) affiliated with industry is not to be interpreted as government or industry endorsement of this code or standard.

ASME accepts responsibility for only those interpretations issued in accordance with governing ASME procedures and policies which preclude the issuance of interpretations by individual volunteers.

The footnotes in this document are part of this American National Standard.

ADDENDA

Colored-sheet Addenda, which include additions and revisions to individual Sections of the Code, are published annually and will be sent automatically to purchasers of the applicable Sections up to the publication of the 2001 Code. The 1998 Code is available only in the loose-leaf format; accordingly, the Addenda will be issued in the loose-leaf, replacement-page format.

INTERPRETATIONS

ASME issues written replies to inquiries concerning interpretation of technical aspects of the Code. The Interpretations for each individual Section will be published separately and will be included as part of the update service to that Section. They will be issued semiannually (July and December) up to the publication of the 2001 Code. Interpretations of Section III, Divisions 1 and 2, will be included with the update service to Subsection NCA.

CODE CASES

The Boiler and Pressure Vessel Committee meets regularly to consider proposed additions and revisions to the Code and to formulate Cases to clarify the intent of existing requirements or provide, when the need is urgent, rules for materials or constructions not covered by existing Code rules. Those Cases which have been adopted will appear in the appropriate 1998 Code Cases book: (1) Boilers and Pressure Vessels and (2) Nuclear Components. Supplements will be sent automatically to the purchasers of the Code Cases books up to the publication of the 2001 Code.

Page v

FOREWORD

The American Society of Mechanical Engineers set up a committee in 1911 for the purpose of formulating standard rules for the construction of steam boilers and other pressure vessels. This committee is now called the Boiler and Pressure Vessel Committee.

The Committee's function is to establish rules of safety governing the design, fabrication, and inspection during construction of boilers and pressure vessels, and to interpret these rules when questions arise regarding their intent. In formulating the rules, the Committee considers the needs of users, manufacturers, and inspectors of pressure vessels. The objective of the rules is to afford reasonably certain protection of life and property and to provide a margin for deterioration in service so as to give a reasonably long, safe period of usefulness. Advancements in design and material and the evidence of experience have been recognized.

This Code contains mandatory requirements, specific prohibitions, and nonmandatory guidance for construction,¹ and inservice inspection and testing activities. The Code does not address all aspects of these activities and those aspects which are not specifically addressed should not be considered prohibited. The Code is not a handbook and cannot replace education, experience, and the use of engineering judgment. The phrase *engineering judgment* refers to technical judgments made by knowledgeable engineers experienced in the application of the Code. Engineering judgments must be consistent with Code philosophy and such judgments must never be used to overrule mandatory requirements or specific prohibitions of the Code.

¹ Construction, as used in this Foreword, is an all-inclusive term comprising materials, design, fabrication, examination, inspection, testing, certification, and pressure relief.

The Committee recognizes that tools and techniques used for design and analysis change as technology progresses and expects engineers to use good judgment in the application of these tools. The designer is responsible for complying with Code rules and demonstrating compliance with Code equations when such equations are mandatory. The Code neither requires nor prohibits the use of computers for the design or analysis of components constructed to the requirements of the Code. However, designers and engineers using computer programs for design or analysis are cautioned that they are responsible for all technical assumptions inherent in the programs they use and they are responsible for the application of these programs to their design.

The Code does not fully address tolerances. When dimensions, sizes, or other parameters are not specified with tolerances, the values of these parameters are considered nominal and allowable tolerances or local variances may be considered

acceptable when based on engineering judgment and standard practice as determined by the engineer.

The Boiler and Pressure Vessel Committee deals with the care and inspection of boilers and pressure vessels in service only to the extent of providing suggested rules of good practice as an aid to owners and their inspectors.

The rules established by the Committee are not to be interpreted as approving, recommending, or endorsing any proprietary or specific design or as limiting in any way the manufacturer's freedom to choose any method of design or any form of construction that conforms to the Code rules.

The Boiler and Pressure Vessel Committee meets regularly to consider revisions of the rules, new rules as dictated by technological development, Code Cases, and requests for interpretations. Only the Boiler and Pressure Vessel Committee has the authority to provide official interpretations of this Code. Requests for revisions, new rules, Code Cases, or interpretations shall be addressed to the Secretary in writing and shall give full particulars in order to receive consideration and action (see Mandatory Appendix covering preparation of technical inquiries). Proposed revisions to the Code resulting from inquiries will be presented to the Main Committee for appropriate action. The action of the Main Committee becomes effective only after confirmation by letter ballot of the Committee and approval by ASME.

Proposed revisions to the Code approved by the Committee are submitted to the American National Standards Institute and published in *Mechanical Engineering*

Page viii

to invite comments from all interested persons. After the allotted time for public review and final approval by ASME, revisions are published annually in Addenda to the Code.

Code Cases may be used in the construction of components to be stamped with the ASME Code symbol beginning with the date of their approval by ASME.

Code Editions may be used on or after the date of issue shown in the Edition. After Code revisions are approved by ASME, they may be used beginning with the date of issue shown on the Addenda. Revisions to material specifications are originated by the American Society for Testing and Materials (ASTM) and other recognized national or international organizations, and are usually adopted by ASME. However, those revisions may or may not have any effect on the suitability of material, produced to earlier editions of specifications, for use in ASME construction. ASME material specifications approved for use in each construction Code are listed in the Appendices of Section II, Parts A and B. These Appendices list, for each specification, the latest edition adopted by ASME, and earlier and later editions considered by ASME to be identical for ASME construction.

Owners of nuclear power plants are cautioned that Code Editions, Addenda, and Cases to be used in construction shall be acceptable to the regulatory and enforcement authorities having jurisdiction at the nuclear power plant site.

Each state and municipality in the United States and each province in Canada that adopts or accepts one or more Sections of the Boiler and Pressure Vessel Code is invited to appoint a representative to act on the Conference Committee to the Boiler and Pressure Vessel Committee. Since the members of the Conference Committee are in active contact with the administration and enforcement of the rules, the requirements for inspection in this Code correspond with those in effect in their respective jurisdictions. The required qualifications for an Authorized Inspector under these rules may be obtained from the administrative authority of any state, municipality, or province which has adopted these rules.

The Boiler and Pressure Vessel Committee in the formulation of its rules and in the establishment of maximum design and operating pressures considers materials, construction, method of fabrication, inspection, and safety devices. Permission may be granted to regulatory bodies and organizations publishing safety standards to use a complete Section of the Code by reference. If usage of a Section, such as Section IX, involves exceptions, omissions, or changes in provisions, the intent of the Code might not be attained.

Where a state or other regulatory body, in the printing of any Section of the Boiler and Pressure Vessel Code, makes additions or omissions, it is recommended that such changes be clearly indicated.

The National Board of Boiler and Pressure Vessel Inspectors is composed of chief inspectors of states and municipalities in the United States and of provinces in Canada that have adopted the Boiler and Pressure Vessel Code. This Board, since its organization in 1919, has functioned to uniformly administer and enforce the rules of the Boiler and Pressure Vessel Code. The cooperation of that organization with the Boiler and Pressure Vessel Committee has been extremely helpful.

The Code Committee does not rule on whether a component shall or shall not be constructed to the provisions of the Code. The Scope of each Section has been established to identify the components and parameters considered by the Committee in formulating the Code rules. Laws or regulations issued by municipality, state, provincial, federal, or other enforcement or regulatory bodies having jurisdiction at the location of an installation establish the mandatory applicability of the Code rules, in whole or in part, within their jurisdiction. Those laws or regulations may require the use of this Code for vessels or components not considered to be within its Scope or may establish additions or deletions in that Scope. Accordingly, inquiries regarding such laws or regulations are to be directed to the issuing enforcement or regulatory body.

Questions or issues regarding compliance of a specific component with the Code rules are to be directed to the ASME Certificate Holder (Manufacturer). Inquiries concerning the interpretation of the Code are to be directed to the ASME Boiler and Pressure Vessel Committee. ASME is to be notified should questions arise concerning improper use of an ASME Code symbol.

The specifications for materials given in Section II are identical with or similar to those of specifications published by ASTM, AWS, and other recognized national or international organizations. When reference is made in an ASME material specification to a non-ASME specification for which a companion ASME specification exists, the reference shall be interpreted as applying to the ASME material specification. Not all materials included in the material specifications in Section II have been adopted for use in this Section. Usage is limited to those materials and grades listed in at least one of the tables of Section II, Part D, Subpart 1, identified as applicable to this Section. All materials allowed by this Section and used for construction within the scope of these rules shall be furnished in accordance with material specifications

Page ix

contained in Section II or referenced in Appendices A of Section II, Parts A and B except where otherwise provided in Code Cases or in this Section of the Code. Materials covered by these specifications are acceptable for use in items covered by the Code Sections only to the degree indicated in the applicable Section. Materials for Code use should preferably be ordered, produced, and documented on this basis. Material produced to an acceptable specification with requirements different from the requirements of the corresponding specification listed in Appendix A of Part A or Part B may also be used in accordance with the above, provided the material manufacturer or vessel manufacturer certifies with evidence acceptable to the Authorized Inspector that the corresponding ASME specification requirements of specifications listed in Appendix A of Part A or Part B have been met. Material produced to an acceptable material specification is not limited as to country of origin.

When required by context in this Section, the singular shall be interpreted as the plural, and vice-versa; and the feminine, masculine, or neuter gender shall be treated as such other gender as appropriate.

Publication of the SI (Metric) Edition of the ASME Boiler and Pressure Vessel Code was discontinued with the 1986 Edition. Effective October 1, 1986, the SI Edition was withdrawn as an ASME Boiler and Pressure Vessel Code document.

Page xi

STATEMENT OF POLICY ON THE USE OF CODE SYMBOLS AND CODE AUTHORIZATION IN ADVERTISING

ASME has established procedures to authorize qualified organizations to perform various activities in accordance with the requirements of the ASME Boiler and Pressure Vessel Code. It is the aim of the Society to provide recognition of organizations so authorized. An organization holding authorization to perform various activities in accordance with the requirements of the Code may state this capability in its advertising literature.

Organizations that are authorized to use Code Symbols for marking items or constructions which have been constructed and inspected in compliance with the ASME Boiler and Pressure Vessel Code are issued Certificates of Authorization. It is the aim of the Society to maintain the standing of the Code Symbols for the benefit of the users, the enforcement jurisdictions, and the holders of the symbols who comply with all requirements.

Based on these objectives, the following policy has been established on the usage in advertising of facsimiles of the symbols, Certificates of Authorization, and reference to Code construction. The American Society of Mechanical Engineers does not "approve," "certify," "rate," or "endorse" any item, construction, or activity and there shall be no statements or implications which might so indicate. An organization holding a Code Symbol and/or a Certificate of Authorization may state in advertising literature that items, constructions, or activities "are built (produced or performed) or activities conducted in accordance with the requirements of the ASME Boiler and Pressure Vessel Code," or "meet the requirements of the ASME

Boiler and Pressure Vessel Code."

The ASME Symbol shall be used only for stamping and nameplates as specifically provided in the Code. However, facsimiles may be used for the purpose of fostering the use of such construction. Such usage may be by an association or a society, or by a holder of a Code Symbol who may also use the facsimile in advertising to show that clearly specified items will carry the symbol. General usage is permitted only when all of a manufacturer's items are constructed under the rules.

The ASME logo, which is the cloverleaf with the letters ASME within, shall not be used by any organization other than ASME.

STATEMENT OF POLICY ON THE USE OF ASME MARKING TO IDENTIFY MANUFACTURED ITEMS

The ASME Boiler and Pressure Vessel Code provides rules for the construction of boilers, pressure vessels, and nuclear components. This includes requirements for materials, design, fabrication, examination, inspection, and stamping. Items constructed in accordance with all of the applicable rules of the Code are identified with the official Code Symbol Stamp described in the governing Section of the Code.

Markings such as "ASME," "ASME Standard," or any other marking including "ASME" or the various Code Symbols shall not be used on any item which is not constructed in accordance with all of the applicable requirements of the Code.

Items shall not be described on ASME Data Report Forms nor on similar forms referring to ASME which tend to imply that all Code requirements have been met when, in fact, they have not been. Data Report Forms covering items not fully complying with ASME requirements should not refer to ASME or they should clearly identify all exceptions to the ASME requirements.

CONFERENCE COMMITTEE

D. E. Tanner - Tennessee (*Chair*)

R. D. Reetz - North Dakota (*Vice Chair*)

A. J. Justin - National Board of Boiler and Pressure Vessel Inspectors (*Secretary*)

R. J. Aben, Jr. - Michigan

J. S. Aclaro - Los Angeles, California

E. A. Anderson - Chicago, Illinois

J. Anderson - South Dakota

R. Barkdoll - Washington

F. P. Barton - Virginia

C. Castle - Nova Scotia, Canada

R. R. Cate - Louisiana

L. Chase - Northwest Territories, Canada

R. A. Coomes - Kentucky

J. Corcoran - Connecticut

M. H. Diehl, Jr. - Maryland

D. A. Douin - Illinois

D. Eastman - Newfoundland and Labrador, Canada

G. L. Ebeyer - New Orleans, Louisiana

F. Ellis - New Hampshire

E. Everett - Georgia

P. C. Hackford - Utah

D. Hanrath - North Carolina

J. B. Harlan - Delaware

K. Hynes - Prince Edward Island, Canada

D. T. Jagger - Ohio

D. J. Jenkins - Kansas

M. Kotb - Quebec, Canada

J. P. Larson - Minnesota

K. T. Lau - Alberta, Canada
J. Lemire - California
G. A. Lundberg - Florida
W. C. Lundine - Oregon
M. A. Malek - Maine
I. W. Mault - Manitoba, Canada
H. T. McEwen - Mississippi
A. W. Meiring - Indiana
R. Mile - Ontario, Canada
T. J. Monroe - Oklahoma
Y. Nagpaul - Hawaii
J. D. Payton - Pennsylvania
D. K. Peetz - Missouri
D. C. Price - Yukon Territory, Canada
R. S. Pucek - Wisconsin
T. E. Rennie - Arizona
L. Roussinos - British Columbia, Canada
M. Shuff - West Virginia
R. Snyder - New Jersey
N. Surtees - Saskatchewan, Canada
M. J. Verhagen - Wisconsin
R. B. West - Iowa
M. J. Wheel - Vermont
K. A. White - Nevada
R. K. White - New York
T. F. Wickham - Rhode Island
C. S. Withers - Colorado

SUBCOMMITTEE ON POWER BOILERS (SC I)

J. R. MacKay, *Chair*
M. D. Bernstein, *Vice Chair*
P. D. Stumpf, *Secretary*
D. L. Berger
E. Everett
D. N. French
F. R. Gerety
J. Hainsworth
T. E. Hansen
J. S. Hunter
W. L. Lowry
T. C. McGough
P. A. Molvie
D. K. Parrish
J. T. Pillow
R. G. Presnak
B. W. Roberts
R. D. Schueler, Jr.

Subgroup on Design (SC I)

M. D. Bernstein, *Chair*
R. D. Schueler, Jr., *Vice Chair*
P. A. Molvie, *Secretary*
M. A. Farrugia
J. D. Fishburn
C. F. Jeerings
K. C. Morrison
A. Nassif
N. Surtees
R. V. Wielgoszinski

Subgroup on Fabrication and Examination (SC I)

D. L. Berger, *Chair*
R. E. McLaughlin, *Secretary*
R. W. Boyce
D. N. French
J. Hainsworth
T. E. Hansen
M. H. Iken
J. M. Lyons
J. T. Pillow
M. E. Reese
R. D. Schueler, Jr.

ORGANIZATION OF SECTION III

1. GENERAL

Section III consists of Division 1, Division 2, and Division 3. These Divisions are broken down into Subsections and are designated by capital letters preceded by the letter "N" for Division 1, by the letter "C" for Division 2, and by the letter "W" for Division 3. The following eleven books make up the three Divisions.

Subsection NCA - General Requirements for Division 1 and Division 2

Division 1

Subsection NB - Class 1 Components

Subsection NC - Class 2 Components

Subsection ND - Class 3 Components

Subsection NE - Class MC Components

Subsection NF - Supports

Subsection NG - Core Support Structures

Subsection NH - Class 1 Components in Elevated Temperature Service

Appendices

Division 2 - Code for Concrete Reactor Vessels and Containments

Division 3 - Containment Systems and Transport Packagings for Spent Nuclear Fuel and High Level Radioactive Waste

The Division 2 book includes Subsection CC - Concrete Containments and Division 2 Appendices.

The Division 3 book includes Subsections WA and WB for General Requirements and Class TP (Type B) Containment, respectively.

2. SUBSECTIONS

Subsections are divided into Articles, Subarticles, paragraphs, and, where necessary, subparagraphs and subsubparagraphs.

3. ARTICLES

Articles are designated by the applicable letters indicated above for the Subsections followed by Arabic numbers, such as NB-1000. Where possible, Articles dealing with the same topics are given the same number in each Subsection in accordance with the following general scheme:

Article Number	Title
1000	Introduction or Scope
2000	Material
3000	Design
4000	Fabrication and Installation
5000	Examination
6000	Testing
7000	Overpressure Protection
8000	Nameplates, Stamping, and Reports

The numbering of Articles and the material contained in the Articles may not, however, be consecutive. Due to the fact that the complete outline may cover phases not applicable to a particular Subsection or Article, the rules have been prepared with some gaps in the numbering.

4. SUBARTICLES

Subarticles are numbered in units of 100, such as NB-1100.

5. SUBSUBARTICLES

Subsubarticles are numbered in units of 10, such as NB-2130, and generally have no text. When a number such as NB-1110 is followed by text, it is considered a paragraph.

6. PARAGRAPHS

Paragraphs are numbered in units of 1, such as NB-2121.

7. SUBPARAGRAPHS

Subparagraphs, when they are *major* subdivisions of a paragraph, are designated by adding a decimal followed by one or more digits to the paragraph number, such as B-1132.1. When they are *minor* subdivisions of a paragraph, subparagraphs may be designated by lowercase letters in parentheses, such as NB-2121(a).

8. SUBSUBPARAGRAPHS

Subsubparagraphs are designated by adding lowercase letters in parentheses to the *major* subparagraph numbers, such as NB-1132.1(a). When further subdivisions of *minor* subparagraphs are necessary, subsubparagraphs are designated by adding Arabic numerals in parentheses to the subparagraph designation, such as NB-2121(a)(1).

Page xxiv

9. REFERENCES

References used within Section III generally fall into one of the following four categories.

A. References to Other Portions of Section III

When a reference is made to another Article, Subarticle, or paragraph, all numbers subsidiary to that reference shall be included. For example, reference to NB-3000 includes all material in Article NB-3000; reference to NB-3200 includes all material in Subarticle NB-3200; reference to NB-3230 includes all paragraphs NB-3231 through NB-3236.

B. References to Other Sections

Other Sections referred to in Section III are:

Section II, Materials. When a requirement for a material, or for the examination or testing of a material, is to be in accordance with a specification such as SA-105, SA-370, or SB-160, the reference is to material specifications in Section II.

These references begin with the letter "S."

Section V, Nondestructive Examination. Section V references begin with the letter "T" and relate to the nondestructive examination of material or welds.

Section IX, Welding and Brazing Qualifications. Section IX references begin with the letter "Q" and relate to welding and brazing requirements.

Section XI, Rules for Inservice Inspection of Nuclear Power Plant Components. When a reference is made to inservice inspection, the rules of Section XI shall apply.

C. Reference to Specifications and Standards Other Than Published in Code Sections

(1) Specifications for examination methods and acceptance standards to be used in connection with them are published by the American Society for Testing and Materials. At the time of publication of Section III, some such specifications were not included in Section II of this Code. A reference to ASTM E 71-64 refers to the specification so designated by and published by ASTM, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

² The American National Standards Institute (ANSI) was formerly known as the American Standards Association. Standards approved by the Association were designated by the prefix "ASA" followed by the number of the standard and the year of publication. More recently, the American National Standards Institute was known as the United States of America Standards Institute. Standards were designated by the prefix "USAS" followed by the number of the standard and the year of publication. While the letters of the prefix have changed with the name of the organization, the numbers of the standards have remained unchanged.

(2) Dimensional standards covering products such as valves, flanges, and fittings are sponsored and published by the American Society of Mechanical Engineers and approved by the American National Standards Institute.² When a product is to conform to such a standard, for example ANSI B16.5, the standard is approved by the American National Standards Institute. The applicable year of issue is that suffixed to its numerical designation in Table NB-3132-1, for example ANSI B16.5-1977. Standards published by the American Society of Mechanical Engineers are available from ASME, 22 Law Drive, Box 2300, Fairfield, NJ 07007-2300.

(3) Dimensional and other types of standards covering products such as valves, flanges, and fittings are also published by the Manufacturers Standardization Society of the Valve and Fittings Industry and are known as Standard Practices. When a product is required by these rules to conform to a Standard Practice, for example MSS SP-6, the Standard Practice referred to is published by the Manufacturers Standardization Society of the Valve and Fittings Industry, 127 Park Street, N.E., Vienna, VA 22180. The applicable year of issue of such a Standard Practice is that suffixed to its numerical designation in Table NB-3132-1, for example MSS SP-6-1963.

(4) Specifications for welding and brazing materials are published by the American Welding Society, 550 N.W. LeJeune Road, Miami, FL 33135. Specifications of this type are incorporated in Section II and are identified by the AWS designation with the prefix "SF," for example SFA-5.1.

(5) Standards applicable to the design and construction of tanks and flanges are published by the American Petroleum Institute and have designations such as API-620 and API-2000. When documents so designated are referred to in Section III, they are standards published by the American Petroleum Institute.

D. References to Appendices

Two types of Appendices are used in Section III and are designated Mandatory and Nonmandatory.

(1) Mandatory Appendices contain requirements which must be followed in construction; such references are designated by a Roman numeral followed by Arabic numerals. References to II-1100 or XI-3212, for example, relate to the Mandatory Appendices.

(2) Nonmandatory Appendices provide information or guidance for the use of Section III; such references are designated by a capital letter followed by Arabic numerals. A reference to D-1100, for example, relates to a Nonmandatory Appendix.

July 1, 1998

American Society Of Mechanical Engineers
SEC III D1 ND-1000

ARTICLE ND-1000 INTRODUCTION

Page 1

ND-1100 SCOPE

(a) Subsection ND contains rules for the materials, design, fabrication, examination, testing, overpressure relief, marking, stamping, and preparation of reports by the Certificate Holder of items which are intended to conform to the requirements for Class 3 construction.

(b) The rules of Subsection ND cover the requirements for the strength and pressure integrity of items the failure of which would violate the pressure retaining boundary. The rules cover load stresses, but do not cover deterioration which may occur in service as a result of corrosion, radiation effects, or instability of material. NCA-1130 gives further limits to the rules of this Subsection.

(c) Subsection ND does not contain rules to cover all details of construction of Class 3 vessels and storage tanks. Where complete details are not provided in this Subsection, it is intended that the Certificate Holder, subject to the approval of the Owner or his designee and acceptance by the Inspector, shall provide details of construction which will be consistent with those provided by the rules of this Subsection.

ND-1130 BOUNDARIES OF JURISDICTION APPLICABLE TO THIS SUBSECTION

ND-1131 Boundary of Components

The Design Specification shall define the boundary of a component to which piping or another component is attached. The boundary shall not be closer to a vessel, tank, pump, or valve than:

- (a) the first circumferential joint in welded connections (the connecting weld shall be considered part of the piping);
- (b) the face of the first flange in bolted connections (the bolts shall be considered part of the piping);
- (c) the first threaded joint in screwed connections.

ND-1132 Boundary Between Components and Attachments

ND-1132.1 Attachments

(a) An *attachment* is an element in contact with or connected to the inside or outside of the pressure retaining portion of a component which may have either a pressure retaining or nonpressure-retaining function and either a structural or nonstructural function.

(b) Attachments with a pressure retaining function include items such as stiffeners and branch or vessel opening reinforcement.

(c) Attachments with a nonpressure-retaining function include items such as valve guides, thermal sleeves, turning vanes, and component support load path items such as vessel saddles, support and shear lugs, brackets, pipe clamps, trunnions, and skirts.

(d) Attachments with a structural function (structural attachments) perform a pressure retaining function or are in the component support load path.

(e) Attachments with a nonstructural function (non structural attachments) do not perform a pressure retaining function nor are they in the component support load path. Nonstructural attachments include items such as nameplates, insulation supports, and locating and lifting lugs.

ND-1132.2 Jurisdictional Boundary.

The jurisdictional boundary between a pressure retaining component and an attachment defined in the Design Specification shall not be any closer to the pressure retaining portion of the component than as defined in (a) through (g)

below. Figures ND-1132.2-1 through ND-1132.2-3 are provided as an aid in defining the boundary and construction requirements of this Subsection.

(a) Attachments cast or forged with the component and weld buildup on the component surface shall be considered part of the component.

(b) Attachments, welds, and fasteners having a pressure retaining function shall be considered part of the component.

Page 4

(c) Except as provided in (d) and (e) below, the boundary between a pressure retaining component and an attachment not having a pressure retaining function shall be at the surface of the component.

(d) The first connecting weld of a nonpressure-retaining structural attachment to a component shall be considered part of the component unless the weld is more than $2t$ from the pressure retaining portion of the component, where t is the nominal thickness of the pressure retaining material. Beyond $2t$ from the pressure retaining portion of the component, the first weld shall be considered part of the attachment.

(e) The first connecting weld of a welded nonstructural attachment to a component shall be considered part of the attachment. At or within $2t$ from the pressure retaining portion of the component the first connecting weld shall conform to ND-4430.

(f) Mechanical fasteners used to connect a nonpressure-retaining attachment to the component shall be considered part of the attachment.

(g) The boundary may be located further from the pressure retaining portion of the component than as defined in (a) through (f) above when specified in the Design Specification.

American Society Of Mechanical Engineers

SEC III D1 ND-2000

ARTICLE ND-2000 MATERIAL

Page 9

ND-2100 GENERAL REQUIREMENTS FOR MATERIAL

ND-2110 SCOPE OF PRINCIPAL TERMS EMPLOYED

(a) The term *material* as used in this Subsection is defined in NCA-1220. The term *Material Organization* is defined in NCA-9000.

(b) The term *pressure retaining material* as used in this Subsection applies to items such as vessel shells, heads, and nozzles; pipes, tubes, and fittings; valve bodies, bonnets, and disks; pump casings and covers; and bolting which joins pressure retaining items.

(c) The requirements of this Article make reference to the term *thickness*. For the purpose intended, the following definitions of nominal thickness apply:

(1) *plate* - the thickness is the dimension of the short transverse direction;

(2) *forgings* - the thickness is the dimension defined as follows:

(a) *hollow forgings* - the nominal thickness is measured between the inside and outside surfaces (radial thickness);

(b) *disk forgings* (axial length less than the outside diameter) - the nominal thickness is the axial length;

(c) *flat ring forgings* (axial length less than the radial thickness) - for axial length ≤ 2 in. (51 mm), the axial length is the nominal thickness; for axial length > 2 in. (51 mm), the radial thickness is the nominal thickness;

(d) *rectangular solid forgings* - the least rectangular dimension is the nominal thickness;

(3) *castings*:

(a) thickness t for fracture toughness testing is defined as the nominal pipe wall thickness of the connecting piping;

(b) thickness t for heat treatment purposes is defined as the thickness of the pressure retaining wall of the casting, excluding flanges and sections designated by the designer as nonpressure retaining.

ND-2120 PRESSURE RETAINING MATERIAL

ND-2121 Permitted Material Specifications

(a) Pressure retaining material shall conform to the requirements of one of the specifications for materials listed in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1 and to all of the requirements of this Article which apply to the product form in which the material is used. Attachments which perform a pressure retaining function shall be pressure retaining material.

(b) The requirements of this Article do not apply to material for items not associated with the pressure retaining function of a component, such as shafts, stems, trim, spray nozzles, bearings, bushings, springs, and wear plates, nor to seals, packing, gaskets, valve seats, and ceramic insulating material and special alloys used as seal material in electrical penetration assemblies.

(c) Material made to specifications other than those specified in Tables 1A and 1B, Section II, Part D, Subpart 1 may be used for the following applications:

(1) *Safety valve disks and nozzles* - when the nozzles are internally contained by the external body structure

(2) *Control valve disks and cages* - when valves function for flow control only

(3) *Line valve disks in valves* - whose inlet connections are NPS 2 (DN 50) and smaller.

(d) Material for line fittings, NPS 1 (DN 25) and less, may be of material made to specifications other than those listed in Section II, Part D, provided that the fittings are in conformance with the requirements of ND-3671.4 and the material is determined to be adequate for the service conditions by the piping system designer.

(e) Welding and brazing materials used in manufacture of items shall comply with an SFA specification in Section II, Part C, except as otherwise permitted in Section IX, and shall also comply with the applicable requirements of this Article. The requirements of this

Page 14

Article do not apply to materials used as backing rings or backing strips in welded joints.

(f) The requirements of this Article do not apply to hard surfacing or corrosion resistant weld metal overlay which is 10% or less of the thickness of the base material (ND-3122).

ND-2122 Special Requirements Conflicting With Permitted Material Specifications

Special requirements stipulated in this Article shall apply in lieu of the requirements of the material specifications wherever the special requirements conflict with the material specification requirements [NCA-3856]. Where the special requirements include an examination, test, or treatment which is also required by the material specification, the examination test or treatment need be performed only once. Required nondestructive examinations shall be performed as specified for each product form in ND-2500. Any examination, repair, test, or treatment required by the material specification or by this Article may be performed by the Material Organization or the Certificate Holder as provided in ND-4121.1. Any hydrostatic or pneumatic pressure test required by a material specification need not be performed, provided the material is identified as not having been pressure tested and it is subsequently pressure tested in accordance with ND-6114, except where the location of the material in the component or the installation would prevent performing any nondestructive examination required by the material specification to be performed subsequent to the hydrostatic or pneumatic test.

ND-2124 Material Size Ranges and Tolerances

(a) Material outside the limits of size or thickness given in any specification in Section II may be used if the material is in compliance with the other requirements of the specification and no size limitation is given in this Subsection. In those specifications in which chemical composition or mechanical properties are indicated to vary with size or thickness, any material outside the specification range shall be required to conform to the composition and mechanical properties shown for the nearest specified range [NCA-3856].

(b) Plate material shall be ordered not thinner than the design thickness. Components, except for piping, made of plate furnished with an undertolerance of not more than the smaller value of 0.01 in. (0.3 mm), or 6% of the ordered thickness may be used at the full Design Pressure for the thickness ordered. If the specification to which the plate is ordered allows a greater undertolerance, the ordered thickness of the material shall be sufficiently greater than the design thickness so that the thickness of the material furnished is not more than the smaller of 0.01 in. (0.3 mm) or 6% under the design thickness.

(c) If pipe or tube is ordered by its nominal wall thickness, the manufacturing undertolerance on wall thickness shall be taken into account. The manufacturing undertolerances are given in the several pipe and tube specifications listed in the applicable Tables in Section II, Part D. After the minimum wall thickness is determined (ND-3641.1), it shall be increased by an amount sufficient to provide for the manufacturing undertolerance allowed in the pipe or tube specification.

ND-2125 Materials in Combination¹

A component may be constructed of any combination of materials permitted in ND-2000, provided the applicable rules are followed and the requirements of Section IX for welding dissimilar metals are met.

ND-2126

Integrally finned tubes may be made from tubes that conform to one of the specifications for tubes listed in Tables 1A and 1B, Section II, Part D, Subpart 1 and to all of the special requirements of this Article which apply to that product form. In addition, the following requirements shall apply.

(a) The requirements of ND-2550 shall be met by the tube before finning.

(b) The tubes, after finning, shall conform to the applicable heat treatment requirements of the basic material specification.

(c) The allowable stress values shall be those given in Tables 1A and 1B, Section II, Part D, for the tube material from which the finned tube is made.

(d) After finning, each tube shall be subjected to one of the following tests:

(1) an internal pneumatic pressure test at not less than 250 psi (1720 kPa) without evidence of leakage. The test method, such as immersion of the tube under water during the test, shall permit visual detection of any leakage.

1 Because of the different thermal coefficients of expansion of dissimilar materials, caution shall be exercised in construction under the provisions of this paragraph in order to avoid difficulties inservice under extreme temperature conditions, or with unusual restraint such as may occur at points of stress concentration and also because of metallurgical changes occurring at high temperatures.

Page 15

(2) an individual tube hydrostatic test at 1.25 times the Design Pressure which permits complete examination of the tube for leakage.

(e) A visual examination shall be performed after finning. Material having discontinuities, such as laps, seams, or cracks, is unacceptable.

ND-2128 Bolting Material

(a) Material for bolts and studs shall conform to the requirements of one of the specifications listed in Table 3, Section II, Part D, . Material for nuts shall conform to SA-194 or to the requirements of one of the specifications for nuts or bolting listed in Table 3, Section II, Part D, .

(b) The use of washers is optional. When used, they shall be made of wrought material, with mechanical properties compatible with the nuts with which they are to be employed.

ND-2130 CERTIFICATION OF MATERIAL

All materials used in construction of components shall be certified as required in NCA-3862 and NCA-3861. Certified Material Test Reports are required for pressure retaining material, except as provided by NCA-3861, and for small products as defined in ND-2610(c). A Certificate of Compliance may be provided in lieu of a Certified Material Test Report for all other material. Copies of all Certified Material Test Reports and Certificates of Compliance applicable to material used in a component shall be furnished with the material.

ND-2140 WELDING MATERIAL

For the requirements governing the material to be used for welding, see ND-2400.

ND-2150 MATERIAL IDENTIFICATION

All material shall be marked in accordance with the marking requirements of the material specification. Material for small items shall be controlled during manufacture and installation of the component so that they are identifiable as acceptable material at all times. Welding and brazing material shall be controlled during the repair of material and the manufacture and installation so that they are identifiable as acceptable until the material is actually consumed in the process (ND-4122).

ND-2160 DETERIORATION OF MATERIAL IN SERVICE

Consideration of deterioration of material caused by service is generally outside the scope of this Subsection. It is the responsibility of the Owner to select material suitable for the conditions stated in the Design Specifications (NCA-3250),

with specific attention being given to the effects of service conditions upon the properties of the material.

ND-2170 HEAT TREATMENT TO ENHANCE IMPACT PROPERTIES

Carbon steels, low alloy steels, and high alloy chromium (Series 4XX) steels may be heat treated by quenching and tempering to enhance their impact properties. Postweld heat treatment of the component at a temperature of not less than 1100°F (593°C) may be considered to be the tempering phase of the heat treatment.

ND-2180 PROCEDURES FOR HEAT TREATMENT OF MATERIAL

When heat treating temperature or time is required by the material specification and the rules of this Subsection, the heat treating shall be performed in temperature-surveyed and -calibrated furnaces or the heat treating shall be controlled by measurement of material temperature by thermocouples in contact with the material or attached to blocks in contact with the material or by calibrated pyrometric instruments. Heat treating shall be performed under furnace loading conditions such that the heat treatment is in accordance with the material specification and the rules of this Subsection.

ND-2190 NONPRESSURE-RETAINING MATERIAL

(a) Material in the component support load path and not performing a pressure retaining function (see ND-1130) welded to pressure retaining material shall meet the requirements of NF-2000.

(b) Material not performing a pressure retaining function and not in the component support load path (non structural attachments) welded at or within $2t$ of the pressure retaining portion of the component need not comply with ND-2000 or NF-2000 provided the requirements of ND-4430 are met.

Page 16

(c) Structural steel rolled shapes, which are permitted by this Subsection to be furnished with a Certificate of Compliance, may be repaired by welding using the welders, documentation, and examination requirements specified in SA-6.

ND-2200 MATERIAL TEST COUPONS AND SPECIMENS FOR FERRITIC STEEL MATERIAL

ND-2210 HEAT TREATMENT REQUIREMENTS

ND-2211 Test Coupon Heat Treatment for Ferritic Material²

Where ferritic steel material is subjected to heat treatment during fabrication or installation of a component, the material used for the tensile and impact test specimens shall be heat treated in the same manner as the component, except that test coupons and specimens for P-No. 1 material with a nominal thickness of 2 in. (51 mm) or less are not required to be so heat treated where nominal thickness for flanges refers to the wall thickness at the weld joint to the pipe or component. The Certificate Holder shall provide the Material Organization with the temperature and heating and cooling rate to be used. In the case of postweld heat treatment, the total time at temperature or temperatures for the test material shall be at least 80% of the total time at temperature or temperatures during actual postweld heat treatment of the material, and the total time at temperature or temperatures for the test material, coupon, or specimen may be performed in a single cycle.

ND-2212 Test Coupon Heat Treatment for Quenched and Tempered Material

ND-2212.1 Cooling Rates.

2 Any postweld heat treatment time which is anticipated to be applied to the material or item after it is completed shall be specified in the Design Specification. The Certificate Holder shall include this time in the total time at temperature specified to be applied to the test specimens.

Where ferritic steel material is subjected to quenching from the austenitizing temperature, the test coupons representing those materials shall be cooled at a rate similar to and no faster than the main body of the material except in the case of certain forgings and castings (ND-2223.3 and ND-2226.4). This rule shall apply for coupons taken directly from the material as well as for separate test coupons representing the material, and one of the general procedures described in ND-2212.2 or one of the specific procedures described in ND-2220 shall be used for each product form.

ND-2212.2 General Procedures.

One of the general procedures in (a), (b), and (c) below may be applied to quenched and tempered material or test coupons representing the material, provided the specimens are taken relative to the surface of the product in accordance with ND-2220. Further specific details of the methods to be used shall be the obligation of the Material Organization and the Certificate Holder.

(a) Any procedure may be used which can be demonstrated to produce a cooling rate in the test material that matches the cooling rate of the main body of the product at the region midway between midthickness and the surface ($\frac{1}{4}t$) and no nearer any heat treated edge than a distance equal to the nominal thickness t being quenched within 25°F (14°C) and 20 sec at all temperatures after cooling begins from the austenitizing temperature.

(b) If cooling rate data for the material and cooling rate control devices for the test specimens are available, the test specimens may be heat treated in the device to represent the material provided that the provisions of (a) above are met.

(c) When any of the specific procedures described in ND-2220 are used, faster cooling rates at the edges may be compensated for by:

- (1) taking the test specimens at least t from a quenched edge, where t equals the material thickness;
- (2) attaching a steel pad at least t wide by a partial penetration weld (which completely seals the buffered surface) to the edge where specimens are to be removed; or
- (3) using thermal barriers or insulation at the edge where specimens are to be removed.

It shall be demonstrated (and this information shall be included in the Certified Material Test Report) that the cooling rates are equivalent to (a) or (b) above.

ND-2220 PROCEDURE FOR OBTAINING TEST COUPONS AND SPECIMENS FOR QUENCHED AND TEMPERED MATERIAL

ND-2221 General Requirements

The procedure for obtaining test specimens for quenched and tempered material is related to the product form. Coupon and specimen location shall be as required by the material specification, except as stated in the following paragraphs of this Subarticle. References to dimensions signify nominal values.

Page 17

ND-2222 Plates

ND-2222.1 Orientation and Location of Coupons.

Coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from a rolled surface and with the midlength of the specimen at least t from any heat treated edge, where t is the nominal thickness of the material.

ND-2222.2 Requirements for Separate Test Coupons.

Where a separate test coupon is used to represent the component material, it shall be of sufficient size to ensure that the cooling rate of the region from which the test coupons are removed represents the cooling rate of the material at least $\frac{1}{4}t$ deep and t from any edge of the product. Unless cooling rates applicable to the bulk pieces or product are simulated in accordance with ND-2212.2, the dimensions of the coupon shall be not less than $3t \times 3t \times t$, where t is the nominal material thickness.

ND-2223 Forgings and Forged Bars

ND-2223.1 Location of Test Coupons.

The longitudinal axis of the test specimens shall be located at least $\frac{1}{4}t$ from the nearest surface. The gage length of

4

tension test specimens and the area under the notch of Charpy specimens shall be located at a distance of at least t from any second surface to compensate for faster cooling rates at the edges. t is the maximum nominal heat treated thickness or cross section of the forging. Either of the following methods may be used to obtain the required distance from any second surface.

(a) *Method A.* A thermal buffer ring, at least $t \times t$ in cross section, or sections of such a ring at least $3t$ in length, shall be welded to the test end of a forging prior to heat treatment for mechanical properties. The buffer material may be any weldable carbon or low alloy steel and shall be joined to the forging with a partial penetration-type weld that completely seals the buffered surface. The test coupons shall be removed from the forging in the region buffered by the ring or ring segments. If ring segments are used, the test coupons shall be removed from the forging in the area under the center one-third of the buffer ring segment length. In either case, the longitudinal axis of the test specimens shall be located at a minimum distance of $\frac{1}{2}$ in. (13 mm) from the buffered surface of the forging, and at least $\frac{1}{4}t$ from a quenched surface of the forging.

(b) *Method B.* Thermal insulation or other thermal barriers shall be used during the heat treatment adjacent to the product surface where specimens are to be removed. It shall be demonstrated that the cooling rate of the test specimen location is no faster than that attained by the method described in ND-2223.1, or Method A. Test specimen locations shall be the same as stated for Method A. Details of thermal insulation, including substantiation data, shall be available from the agency performing the heat treatment.

ND-2223.2 Very Thick and Complex Forgings.

For forgings that are very thick and complex (for example, thick tubesheets, flanges, nozzles, pump and valve bodies, and other complex forgings that are contour-shaped or machined essentially to the inservice configuration prior to heat treatment), the purchaser shall specify the surfaces of the finished product subjected to significant tension loading in service. The test specimens shall be removed from a prolongation or other stock from the forging or from a test forging in accordance with ND-2223.4. They shall be taken so that the longitudinal center line is at a distance below the nearest heat treated surface equivalent to at least the greatest distance that the significantly stressed location is from the nearest heat treated surface. The gage length of tension test specimens and the area under the notch of Charpy specimens, shall be located at least twice this distance from any second heat treated surface. These respective locations, however, shall not be closer than $\frac{3}{4}$ in. (19 mm) from the nearest surface and $1\frac{1}{2}$ in. (38 mm) from any second surface.

ND-2223.3 Multiple Forgings

(a) *Multiple Forgings Separated Into Identical Individual Forgings Prior to Quenching and Tempering Treatment.* At least one individual forging from each multiple forging in each heat treating lot shall be tested using the test specimen locations of ND-2223.1 or ND-2223.2 as specified on the purchase order, except that test specimens located at midlength may be closer to the ends of the production forging than the specified distance to the second surfaces. All forgings shall be quenched simultaneously and tempered in the same furnace charge. All forgings from the multiple shall be Brinell hardness tested after heat treatment and forgings not tested for mechanical properties shall have a BHN within 20 points of the BHN of the forging that has been tested for mechanical properties.

(b) *Multiple Forgings Separated After Quench and Temper Treatment.* The multiple forging shall have an integral prolongation and when the heat treated length of the multiple (excluding test metal) exceeds 80 in. (2030 mm), each end shall have an integral prolongation. Test specimen locations shall meet the requirements of ND-2223.1 or ND-2223.2 as specified on the purchase order.

Page 18

ND-2223.4 Forgings Tested With Representative, Separately Forged Test Pieces.

Separately forged test pieces shall be used. Test specimens shall be taken from a representative separate test forging made from the same heat of steel as the production forgings. Separate test forgings shall receive substantially the same reduction and type of hot working as the production forgings, except that a longitudinal forged bar with dimensions not less than $3t \times t$ may be used to represent a ring forging. Test forgings shall be of the same nominal thickness as the as-quenched production forgings, and shall be heat treated in the same furnace charge and under the same conditions as the production forgings. For forgings requiring impact testing, the use of representative separate test pieces shall be

limited to forgings with machined weights of 1,000 lb (454 kg) or less, except in the case of forgings covered by ND-2223.1. Test specimen locations shall meet the requirements of ND-2223.1 or ND-2223.2 as applicable. When destructively tested production forgings are not of sufficient length to obtain the t distance from a second surface, the location from the second surface may be at midlength of the forging.

ND-2223.5 Quenched and Tempered Bars

(a) For bars (other than those used for bolting materials) the coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from the outside or rolled surface. The gage length of tension test specimens and the area under the notch of Charpy specimens shall be indented at least one diameter or thickness from a heat treated end.

(b) *Bars With Thicknesses Exceeding $1\frac{1}{2}$ in. (38 mm).* For bars (other than those used for bolting materials) with diameters or thickness over $1\frac{1}{2}$ in. (38 mm), the coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from the outside or rolled surface. The gage length of tension test specimens and the area under the notch of Charpy specimens shall be located at least one diameter or thickness from a heat treated end.

ND-2224 Bars and Bolting Material

ND-2224.1 Bars With 2 in. (51 mm) Maximum Thickness.

For bars with diameters or thicknesses 2 in. (51 mm) or less, the coupons shall be taken so that specimens shall have their longitudinal axes on a line representing the center of the thickness and with the midlength of the specimens at least one diameter or thickness from a heat treated end.

ND-2224.2 Bars With Thicknesses Exceeding 2 in. (51 mm).

For bars with diameters or thicknesses over 2 in. (51 mm), the coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from the outside or rolled surface and with the midlength of the specimens at least t from a heat treated end, where t is either the bar diameter or thickness.

ND-2224.3 Bolting Material.

For bolting material, the coupons shall be taken in conformance with the applicable material specification and with the midlength of the specimen at least one diameter or thickness from a heat treated end. When the studs, nuts, or bolts are not of sufficient length, the midlength of the specimen shall be at the midlength of the studs, nuts, or bolts. The studs, nuts, or bolts selected to provide test coupon material shall be identical with respect to the quenched contour and size except for length, which shall equal or exceed the length of the represented studs, nuts, or bolts.

ND-2225 Tubular Products

ND-2225.1 Tubular Products With 2 in. (51 mm) Maximum Thickness.

For tubular products with 2 in. (51 mm) maximum wall thickness, the coupons shall be taken so that specimens shall have their longitudinal axes on a surface midway between the outside and inside surfaces and with the midlength of the specimens at least one wall thickness from a heat treated end.

ND-2225.2 Tubular Products Exceeding 2 in. (51 mm) Nominal Thickness.

For tubular products with nominal wall thicknesses exceeding 2 in. (51 mm), the coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from the outside surface and with the midlength of the specimens at least one wall thickness from a heat treated end.

ND-2225.3 Separately Produced Coupons Representing Fittings.

Separately produced test coupons representing fittings may be used. When separately produced coupons are used, the requirements of ND-2223.4 shall be met.

ND-2226 Tensile Test Specimen Location (for Quenched and Tempered Ferritic Steel Castings)

NOTE: Users of this requirement should note that the hardenability of some grades may limit the usable section size.

(a) This section applies only to quenched and tempered ferritic steel castings with a thickness t exceeding 2 in. (51 mm), where t is the thickness of the pressure retaining wall of the casting, excluding flanges and sections designated by the designer as nonpressure-retaining. The order, inquiry, and drawing shall designate what the thickness t is for the casting.

(b) One of the following shall apply.

(1) The longitudinal centering of the thickness of the tension test specimen, shall be taken at least $\frac{1}{4}t$ from the t dimension surface. For cylindrical castings, the longitudinal center line of the specimens shall be taken at least $\frac{1}{4}t$ from the outside or inside surface and the gage length at least t from the as-heat-treated end.

(2) Where separately cast test coupons are used, their dimensions shall be not less than $3t \times 3t \times t$ and each specimen cut from it shall meet the requirements of (b). The test coupon shall be of the same heat of steel and shall receive substantially the same casting practices as the production casting it represents. (Centrifugal castings may be represented by statically cast coupons.) The test coupon shall be heat treated under the same conditions as the production casting(s). The t dimension of the test coupon shall be the same maximum thickness t as defined in (a) above. Where separate test blocks require reheat treatment, thermal buffers in accordance with (b) may be used.

(3) Where specimens are to be removed from the body of the casting, a steel thermal buffer pad $1t \times 1t \times$ at least $3t$ shall be joined to the casting surface by a partial penetration weld completely sealing the buffered surface prior to the heat treatment process. The test specimens shall be removed from the casting in a location adjacent to the center third of the buffer pad. They shall be located at a minimum distance of $\frac{1}{2}$ in. (13 mm) from the buffered surface and $\frac{1}{4}t$ from the other heat treated surfaces.

(4) Where specimens are to be removed from the body of the casting, thermal insulation or other thermal barriers shall be used during the heat treatment process adjacent to the casting edge where specimens are to be removed. It shall be demonstrated that the cooling rate of the test specimen is no faster than that of specimens taken by the method described in (b)(1) above. This information shall be included in the test reports.

(5) Where castings are cast or machined to essentially the finished product configuration prior to heat treatment, the test specimens shall be removed from a casting prolongation or other stock on the product at a location below the nearest heat treated surface indicated on the order. The specimens shall be located with their longitudinal axes a distance below the nearest heat treated surface equivalent to at least the greatest distance that the indicated high tensile stress surface will be from the nearest heat treated surface and with their midlength a minimum of twice this distance from a second heat treated surface. In any case, the longitudinal axes of the test specimens shall be no nearer than $\frac{1}{4}$ in. (6 mm) to a heat treated surface and the midlength shall be at least $1\frac{1}{2}$ in. (38 mm) from a second heat treated surface. The component manufacturer shall specify the surfaces of the finished product subjected to high tensile stress in service.

ND-2300 FRACTURE TOUGHNESS REQUIREMENTS FOR MATERIAL

ND-2310 MATERIAL TO BE IMPACT TESTED

ND-2311 Material for Which Impact Testing Is Required

(a) Pressure retaining material shall be impact tested in accordance with the requirements of ND-2330, except that impact testing of the material described in (1) through (9) below is not a requirement of this Sub-section:

(1) material with a nominal section thickness of $\frac{5}{8}$ in. (16 mm) and less where the thickness shall be taken as defined in (a) through (d) below:

(a) for pumps, valves, and fittings, use the largest nominal pipe wall thickness of the connecting pipes;

(b) for vessels and tanks, use the nominal thickness of the shell or head, as applicable;

(c) for nozzles or parts welded to vessels, use the lesser of the vessel shell thickness to which the item is welded or the maximum radial thickness of the item exclusive of integral shell butt welding projections;

- (d) for flat heads, tubesheets, or flanges, use the maximum shell thickness associated with the butt welding hub;
- (2) bolting, including studs, nuts, and bolts, with a nominal size of 1 in. (25 mm) and less;
- (3) bars with a nominal cross-sectional area of 1 sq in. (645 mm²) and less;

**TABLE ND-2311-1
EXEMPTIONS FROM IMPACT TESTING UNDER ND-2311(a)(8)**

Material	Material Condition [Note (1)]	Lowest Service Temperature for the Thickness Shown			
		Over $\frac{5}{8}$ in. to $\frac{3}{4}$ in., Incl.	Over $\frac{3}{4}$ in. to 1 in., Incl.	Over 1 in. to $1\frac{1}{2}$ in., Incl.	Over $1\frac{1}{2}$ in. to $2\frac{1}{2}$ in., Incl.

NOTES:

(1) Material Condition letters refer to:

N — Normalize

Q & T — Quench and Temper

(2) The lowest service temperature shown in the column Over $1\frac{1}{2}$ in. to $2\frac{1}{2}$ in. may be used for these thicknesses.

(3) Material made to a fine grain melting practice.

TABLE ND-2311-1 EXEMPTIONS FROM IMPACT TESTING UNDER ND-2311(a)(8)

- (4) all thicknesses of material for pipe, tube, fittings, pumps, and valves with a NPS 6 diameter (DN 150) and smaller;
- (5) material for pumps, valves, and fittings with all pipe connections of $\frac{5}{8}$ in. (16 mm) nominal wall thickness and less;
- (6) austenitic stainless steel;
- (7) nonferrous material;
- (8) materials listed in Table ND-2311-1 in the thicknesses shown and for Lowest Service Temperatures³ equal to or more than the tabulated temperatures. This exemption does not exempt either the weld metal (ND-2430) or the welding procedure qualification (ND-4335) from impact testing.
- (9) materials for components for which the Lowest Service Temperature exceeds 100°F (38°C).
- (b) The Design Specification shall state the Lowest Service Temperature for the component.

ND-2320 IMPACT TEST PROCEDURES

ND-2321 Charpy V-Notch Tests

³ Lowest Service Temperature (LST) is the minimum temperature of the fluid retained by the component, or, alternatively, the calculated minimum metal temperature whenever the pressure within the component exceeds 20% of the preoperational system hydrostatic test pressure.

The Charpy V-notch test C_v , when required, shall be performed in accordance with SA-370. Specimens shall be in accordance with SA-370, Fig. 11, Type A. A test shall consist of a set of three full-size 10 mm × 10 mm specimens. The lateral expansion and absorbed energy, as applicable, and the test temperature, as well as the orientation and location of all tests performed to meet the requirements of ND-2330 shall be reported in the Certified Material Test Report.

ND-2322 Test Specimens

ND-2322.1 Location of Test Specimens.

Impact test specimens shall be removed from the locations specified for tensile test specimens in the material specification. For bolting, the C_v impact test specimens shall be taken with the longitudinal axis of the specimen located at least one-half radius or 1 in. (25 mm) below the surface plus the machining allowance per side, whichever is less. The fracture plane of the specimen shall be at least one diameter or thickness from the heat treated end, except when the studs, nuts, or bolts are not of sufficient length, the midlength of the specimen shall be at the midlength of the studs, nuts, or bolts. The studs, nuts, or bolts selected to provide test coupon material shall be identical with respect to the quenched contour and size, except for length, which shall equal or exceed the length of the represented studs, nuts, or bolts.

ND-2322.2 Orientation of Impact Test Specimens.

Specimens for C_v impact tests shall be oriented as

Page 21

required in ND-2200 for the tensile test specimen, or, alternatively, the orientation may be in the direction of maximum stress. The notch of the C_v specimen shall be normal to the surface of the material.

ND-2330 TEST REQUIREMENTS AND ACCEPTANCE STANDARDS

ND-2331 Pressure Retaining Material Other Than Bolting

Pressure retaining material other than bolting for vessels, tanks, piping (pipe and tubes), pumps, valves, and fittings shall be tested as required by (a) and (b) below.

(a) A Charpy V-notch test shall be performed at a temperature lower than or equal to the Lowest Service Temperature. All three specimens shall meet one of the acceptance standards applicable to the specific test method.

(1) *Charpy V-Notch Testing for the Lateral Expansion Values.* The test results of the three specimens, collectively and singly, shall meet the respective requirements of Table ND-2331(a)-1.

(2) *Charpy V-Notch Testing for Absorbed Energy Values.* The test results of the three specimens, collectively and singly, shall meet the respective requirements of Table ND-2331(a)-2.

(b) Apply the procedures of (a) above to:

(1) the base material;

(2) the base material, the heat affected zone, and weld metal from the weld procedure qualification tests in accordance with ND-4330; and

(3) the weld metal of ND-2431.

ND-2333 Bolting Material

For bolting material, including studs, nuts, and bolts, a Charpy V-notch test shall be performed at a temperature equal to or less than the preload temperature or the Lowest Service Temperature, whichever is less. All three specimens shall meet the requirements of Table ND-2333-1.

ND-2340 NUMBER OF IMPACT TESTS REQUIRED

ND-2341 Plates

TABLE ND-2331(a)-1
REQUIRED C_v LATERAL EXPANSION VALUES^{1,2}
FOR PRESSURE RETAINING MATERIAL
(EXCEPT BOLTING)

Nominal Wall Thickness, in. [Note (3)]	Lateral Expansion, mils	
	Average of 3	Lowest 1 of 3
$\frac{5}{8}$ in. or less [Note (4)]	...	...
Over $\frac{5}{8}$ in. to $\frac{3}{4}$ in., incl.	13	10
Over $\frac{3}{4}$ in. to 1 in., incl.	15	10
Over 1 in. to $1\frac{1}{2}$ in., incl.	20	15
Over $1\frac{1}{2}$ in. to $2\frac{1}{2}$ in., incl.	25	20
Over $2\frac{1}{2}$ in.	30	25

NOTES:

- (1) When two base materials having different specified minimum lateral expansion values are joined, the weld impact lateral expansion requirements of the welding procedure qualification (ND-4330) shall conform to the requirements of either of the base materials.
- (2) When the weld metal tests of ND-2400 are performed to these requirements, the impact lateral expansion shall conform to the requirements of either of the base materials being joined.
- (3)(a) For pumps, valves, and fittings, use the largest nominal wall thickness of the connecting pipes.
- (b) For vessels and tanks, use the nominal thickness of the shell or head, as applicable.
- (c) For nozzles or other items welded to vessels, use the lesser of the vessel shell thickness to which the item is welded or the maximum radial thickness of the item exclusive of integral shell butt welding projections.
- (d) For flat heads, tubesheets, or flanges, use the maximum shell thickness associated with the butt welding hub.
- (4) No test required.

TABLE ND-2331(a)-1 REQUIRED C_V LATERAL EXPANSION VALUES^{1,2} FOR PRESSURE RETAINING MATERIAL (EXCEPT BOLTING)

A Charpy V-notch test shall be performed for each plate as heat treated. Where plates are furnished in the unheat-treated condition and qualified by heat treated test specimens, one test shall be made for each plate as-rolled. The term *as-rolled* refers to the plate rolled from a slab or directly from an ingot, not to its heat treated condition.

ND-2342 Forgings and Castings

(a) Where the weight of an individual forging or casting is less than 1000 lb (454 kg), one test shall be made to represent each heat in each heat treatment charge.

(b) When heat treatment is performed in a continuous-type furnace with suitable temperature controls and equipped with recording pyrometers so that complete heat treatment records are available, a heat treatment charge shall be considered as the lesser of a continuous run not exceeding 8 hr duration or a total weight, so treated, not exceeding 2000 lb (907 kg).

(c) One test shall be made for each forging or casting of 1000 lb to 10,000 lb (454 kg to 4540 kg) in weight.

(d) As an alternative to ND-2342(c), a separate test forging or casting may be used to represent forgings

Page 22

or castings of different sizes in one heat and heat treat lot, provided the test piece is a representation of the greatest thickness in the heat treat lot. In addition, test forgings shall have been subjected to substantially the same reduction and working as the forgings represented.

TABLE ND-2331(a)-2
REQUIRED C_V ENERGY VALUES^{1,2} FOR PRESSURE
RETAINING MATERIAL (EXCEPT BOLTING)

Nominal Wall Thickness [Note (3)]	Energy, ft-lb, for Materials of Specified Minimum Yield Strength, ksi					
	40 ksi or Below		Over 40 ksi to 55 ksi		Over 55 ksi to 105 ksi	
	Average of 3	Lowest 1 of 3	Average of 3	Lowest 1 of 3	Average of 3	Lowest 1 of 3
$\frac{5}{8}$ in. or less [Note (4)]	...	...	...	...	...	...
Over $\frac{5}{8}$ in. to $\frac{3}{4}$ in., incl.	13	10	15	10	20	15
Over $\frac{3}{4}$ in. to 1 in., incl.	15	10	20	15	25	20
Over 1 in. to $1\frac{1}{2}$ in., incl.	20	15	25	20	30	25
Over $1\frac{1}{2}$ in. to $2\frac{1}{2}$ in., incl.	25	20	35	30	40	35
Over $2\frac{1}{2}$ in.	30	25	40	35	45	40

NOTES:

- (1) When two base materials having different specified minimum energy values are joined, the weld impact energy requirements of the welding procedure qualification (ND-4330) shall conform to the requirements of either of the base materials.
- (2) When the weld metal tests of ND-2400 are performed to these requirements, the impact energy shall conform to the requirements of either of the base materials being joined.
- (3)(a) For pumps, valves, and fittings, use the largest nominal wall thickness of the connecting pipes.
(b) For vessels and tanks, use the nominal thickness of the shell or head, as applicable.
(c) For nozzles or other items welded to vessels, use the lesser of the vessel shell thickness to which the item is welded or the maximum radial thickness of the item exclusive of integral shell butt welding projections.
(d) For flat heads, tubesheets, or flanges, use the maximum shell thickness associated with the butt welding hub.
- (4) No test required.

TABLE ND-2331(a)-2 REQUIRED C_V ENERGY VALUES^{1,2} FOR PRESSURE RETAINING MATERIAL (EXCEPT BOLTING)

**TABLE ND-2333-1
REQUIRED C_v VALUES FOR
BOLTING MATERIAL**

Nominal Diameter, in.	Lateral Expansion, mils	Absorbed Energy, ft-lb
1 or less	No test required	No test required
Over 1 through 4	15	30
Over 4	20	35

TABLE ND-2333-1 REQUIRED C_v VALUES FOR BOLTING MATERIAL

(e) Forgings or castings larger than 10,000 lb (4540 kg) shall have two tests per part for Charpy V-notch. The location of C_v impact test specimens shall be selected so that an equal number of specimens is obtained from positions in the forging or casting 180 deg apart.

(f) As an alternative to ND-2342(e) for static castings, a separately cast coupon [ND-2226(b)(2)] may be used; one test shall be made for Charpy V-notch.

ND-2343 Bars

One test shall be made for each lot of bars with cross-sectional area greater than 1 sq in. (645 mm²) where a lot is defined as one heat of material heat treated in one charge or as one continuous operation, not to exceed 6000 lb (2720 kg).

ND-2344 Tubular Products and Fittings

On products which are seamless or welded without filler metal, one test shall be made from each lot. On products which are welded with filler metal, one additional test with the specimens taken from the weld area shall also be made on each lot. A lot shall be defined as stated in the applicable material specification, but in no case shall a lot consist of products from more than one heat of material and of more than one diameter, with the nominal thickness of any product included not exceeding that to be impact tested by more than $\frac{1}{4}$ in. (6 mm); such a lot shall be in a single heat treatment load or in the same continuous run in a continuous furnace controlled within a 50°F (28°C) range and equipped with recording pyrometers.

Page 23

ND-2345 Bolting Material

One test shall be made for each lot of material where a lot is defined as one heat of material heat treated in one charge or as one continuous operation, not to exceed in weight the following:

$1\frac{3}{4}$ in. diameter and less	1,500 lb
$1\frac{3}{4}$ in. to $2\frac{1}{2}$ in. diameter	3,000 lb

Over 5 in. diameter

6,000 lb

10,000 lb

ND-2350 RETESTS

ND-2351 Retests for Material Other Than Bolting

(a) For Charpy V-notch tests required by ND-2330, one retest at the same temperature may be conducted, provided:

(1) the average value of the test results meets the average of three requirements specified in Table ND-2331(a)-1 or Table ND-2331(a)-2, as applicable;

(2) not more than one specimen per test is below the lowest one of three requirements specified in Table ND-2331(a)-1 or Table ND-2331(a)-2, as applicable;

(3) the specimen not meeting the requirements is not lower than 5 ft-lb (6.8 J) or 5 mils (0.13 mm) below the lowest one of three requirements specified in Table ND-2331(a)-1 or Table ND-2331(a)-2, as applicable.

(b) A retest consists of two additional specimens taken as near as practicable to the failed specimens. For acceptance of the retests, both specimens shall be equal to or greater than the average of three requirements specified in Table ND-2331(a)-1 or Table ND-2331(a)-2, as applicable.

ND-2352 Retests for Bolting Material

(a) For Charpy V-notch tests required by ND-2330, one retest at the same temperature may be conducted, provided:

(1) not more than one specimen per test is below the acceptance requirements;

(2) the specimen not meeting the acceptance requirements is not lower than 5 ft-lb (6.8 J) or 5 mils (0.13 mm) below the acceptance requirements.

(b) A retest consists of two additional specimens taken as near as practicable to the failed specimens. For acceptance of the retests, both specimens shall meet the specified acceptance requirements.

ND-2360 CALIBRATION OF INSTRUMENTS AND EQUIPMENT

Calibration of temperature instruments and C_v impact test machines used in impact testing shall be performed at the frequency specified in (a) and (b) below.

(a) Temperature instruments used to control test temperature of specimens shall be calibrated and the results recorded to meet the requirements of NCA-3868 at least once in each 3 month interval.

(b) C_v impact test machines shall be calibrated and the results recorded to meet the requirements of NCA-3868. The calibrations shall be performed at least once per year using methods outlined in ASTM E 23-72 and employing standard specimens obtained from the National Institute of Standards and Technology.

ND-2400 WELDING MATERIAL

ND-2410 GENERAL REQUIREMENTS

(a) All welding material used in the construction and repair of components or material, except welding material used for cladding or hard surfacing, shall conform to the requirements of the welding material specification or to the requirements for other welding material as permitted in Section IX. In addition, welding material shall conform to the requirements stated in this Subarticle and to the rules covering identification in ND-2150.

(b) The Certificate Holder shall provide the organization performing the testing with the information listed below, as applicable:

(1) welding process;

- (2) SFA specification and classification;
 - (3) other identification if no SFA specification applies;
 - (4) minimum tensile strength [ND-2431.1(e)] in the as-welded or heat treated condition, or both [ND-2431.1(c)];
 - (5) Charpy V-notch test for material as welded, or heat treated, or both (ND-2331); the test temperature and the lateral expansion or the absorbed energy shall be provided;
 - (6) the preheat and interpass temperature to be used during welding of the test coupon [ND-2431.1(c)];
 - (7) postweld heat treatment time, temperature range, and maximum cooling rate, if the production weld will be heat treated [ND-2431.1(c)];
-

Page 24

- (8) elements for which chemical analysis is required per the SFA specification or WPS, and ND-2432;
- (9) minimum delta ferrite (ND-2433).

ND-2420 REQUIRED TESTS

The required tests shall be conducted for each lot of covered, flux cored, or fabricated electrodes; for each heat of bare electrodes, rod, or wire for use with the OFW, GMAW, GTAW, PAW, and EGW (electrogas welding) processes (Section IX, QW-492); for each heat of consumable inserts; for each combination of heat of bare electrodes and lot of submerged arc flux; for each combination of lot of fabricated electrodes and lot of submerged arc flux; for each combination of heat of bare electrodes or lot of fabricated electrodes and dry blend of supplementary powdered filler metal and lot of submerged arc flux; or for each combination of heat of bare electrodes and lot of electroslag flux. Tests performed on welding material in the qualification of weld procedures will satisfy the testing requirements for the lot, heat, or combination of heat and batch of welding material used, provided the tests required by ND-4000 and this Subarticle are made and the results conform to the requirements of this Article. The definitions in (a) through (h) below apply.

(a) A *dry batch of covering mixture* is defined as the quantity of dry covering ingredients mixed at one time in one mixing vessel; a dry batch may be used singly or may be subsequently subdivided into quantities to which the liquid binders may be added to produce a number of wet mixes.

(b) A *dry blend* is defined as one or more dry batches mixed in a mixing vessel and combined proportionately to produce a uniformity of mixed ingredients equal to that obtained by mixing the same total amount of dry ingredients at one time in one mixing vessel.

(c) A *wet mix* is defined as the combination of a dry batch or dry blend [(a) and (b) above, respectively] and liquid binder ingredients at one time in one mixing vessel.

(d) A *lot of covered, flux cored, or fabricated electrodes* is defined as the quantity of electrodes produced from the same combination of heat of metal and dry batch, dry blend, or chemically controlled mixes of flux or core materials. Alternatively, a lot of covered, flux cored, or fabricated electrodes may be considered one type and size of electrode, produced in a continuous period, not to exceed 24 hr and not to exceed 100,000 lb (45,360 kg), from chemically controlled tube, wire, or strip and a dry batch, a dry blend, or chemically controlled mixes of flux, provided each container of welding materials is coded for identification and trace able to the production period, the shift, line, and the analysis range of both the mix and the rod, tube, or strip used to make the electrode.

(1) *Chemically controlled tube, wire, or strip* is defined as consumable tube, wire, or strip material supplied on coils with maximum of one splice per coil that has been chemically analyzed to assure that the material conforms to the electrode manufacturer's chemical control limits for the specific type of electrode. Both ends of each coil shall be chemically analyzed except that those coils which are splice free need only be analyzed on one end of the coil.

(2) *Chemically controlled mixes of flux* are defined as flux material that has been chemically analyzed to assure that it conforms to the percent allowable variation from the electrode manufacturer's standard for each chemical element for that type electrode. A chemical analysis shall be made on each mix made in an individual mixing vessel after blending.

(e) A *heat of bare electrode, rod, wire, or consumable insert* is defined as the material produced from the same melt of

metal.

(f) Alternatively, for carbon and low alloy steel bare electrode, rod, wire, or consumable inserts for use with SAW, OFW, GMAW, GTAW, PAW, and EGW processes, a heat may be defined as either the material produced from the same melt of metal or the material produced from one type and size of wire when produced in a continuous period [not to exceed 24 hr and not to exceed 100,000 lb (45,360 kg)] from chemically controlled wire, subject to requirements of (1), (2), and (3) below.

(1) For the chemical control of the product of the rod mill, coils shall be limited to a maximum of one splice prior to processing the wire. Chemical analysis shall be made from a sample taken from both ends of each coil of mill coiled rod furnished by mills permitting spliced coil practice of one splice maximum per coil. A chemical analysis need be taken from only one end of rod coils furnished by mills prohibiting spliced coil practice.

(2) Carbon, manganese, silicon, and other intentionally added elements shall be identified to ensure that the material conforms to the SFA or user's material specification.

(3) Each container of wire shall be coded for identification and traceability to the lot, production period, shift, line, and analysis of rod used to make the wire.

(g) A lot of submerged arc or electroslag flux is defined as the quantity of flux produced from the same

Page 25

combination of raw materials under one production schedule.

(h) A dry blend of supplementary powdered filler metal is defined as one or more mixes of material produced in a continuous period, not to exceed 24 hr and not to exceed 20,000 lb (9070 kg) from chemically controlled mixes of powdered filler metal, provided each container of powdered metal is coded for identification and traceable to the production period, the shift, and the mixing vessel. A chemically controlled mix of powdered filler metal is defined as powdered filler metal material that has been chemically analyzed to assure that it conforms to the percent allowable variation from the powdered filler metal manufacturer's standard, for each chemical element, for that type of powdered filler metal. A chemical analysis shall be made on each mix made in an individual mixing vessel after blending. The chemical analysis range of the supplemental powdered filler shall be the same as that of the welding electrode, and the ratio of powder to electrode used to make the test coupon shall be the maximum permitted for production welding.

ND-2430 WELD METAL TESTS

ND-2431 Mechanical Properties Test

Tensile and impact tests shall be made in accordance with this paragraph, of welding materials which are used to join P-Nos. 1, 3, 4, 5, 6, 7, 9, and 11 base materials in any combination, with the exceptions listed in (a) through (d) below:

(a) austenitic stainless steel and nonferrous welding materials;

(b) consumable inserts (backing filler material);

(c) welding material used for GTAW root deposits with a maximum of two layers;

(d) welding material to be used for the welding of base materials exempted from impact testing by ND-2311(a)(1) through (a)(7) or ND-2311(a)(9) shall also be exempted from the impact testing required by this paragraph.

ND-2431.1 General Test Requirements.

The welding test coupon shall be made in accordance with (a) through (f) below using each process with which the weld material will be used in production welding.

(a) Test coupons shall be of sufficient size and thickness such that the test specimens required herein can be removed.

(b) The weld metal to be tested for all processes except electroslag welding shall be deposited in such a manner as to eliminate substantially the influence of the base material on the results of the tests. Weld metal to be used with the electroslag process shall be deposited in such a manner as to conform to one of the applicable Welding Procedure

Specifications (WPS) for production welding, Section IX, QW-201.1. The base material shall conform to the requirements of Section IX, QW-403.1 or QW-403.4, as applicable.

(c) The welding of the test coupon shall be performed within the range of preheat and interpass temperatures that will be used in production welding. Coupons shall be tested in the as-welded condition, or they shall be tested in the applicable postweld heat treated condition when the production welds are to be postweld heat treated. The postweld heat treatment holding time² shall be at least 80% of the maximum time to be applied to the weld metal in production application. The total time for postweld heat treatment of the test coupon may be applied in one heating cycle. The cooling rate from the postweld heat treatment temperature shall be of the same order as that applicable to the weld metal in the component. In addition, weld coupons for weld metal to be used with the electroslag process, which are tested in the as-welded condition or following a postweld heat treatment within the holding temperature ranges of Table ND-4622.1-1 or ND-4622.4(c)-1, shall have a thickness within the range of 0.5 to 1.1 times the thickness of the welds to be made in production. Electroslag weld coupons to be tested following a postweld heat treatment, which will include heating the coupon to a temperature above the Holding Temperature Range of Table ND-4622.1-1 for the type of material being tested, shall have a thickness within the range of 0.9 to 1.1 times the thickness of the welds to be made in production.

(d) Regardless of the welding process or welding material being tested, the tensile specimens and the C_v impact specimens, when required, shall be located and prepared in accordance with the requirements of SFA-5.1, Specification for Mild Steel Covered Electrodes. Drop weight impact test specimens, when required, shall be oriented so that the longitudinal axis is transverse to the weld with the notch in the weld face, or in a plane parallel to the weld face. For impact specimen preparation and testing, the applicable requirements of ND-2321.1 and ND-2321.2 shall apply. The longitudinal axis of the specimen shall be at a minimum depth of $1/4t$ from a surface, where t is the thickness of the test weld.

(e) One all-weld-metal tensile specimen shall be tested and shall meet the specified minimum tensile strength requirements of the base material specification. Where base materials of different specifications are to

Page 26

be welded, the tensile strength results shall conform to either of the base material specifications.

(f) Impact specimens of the weld metal shall be tested when impact tests are required for either of the base materials of the production weld. The weld metal shall conform to the requirements of ND-2330 applicable to the base material. When different requirements exist for the two base materials, the weld metal may conform to either of the two requirements.

[98]

ND-2431.2 Standard Test Requirements.

In lieu of the use of the General Test Requirements specified in ND-2431.1, tensile and impact tests may be made in accordance with this subparagraph when they are required for mild and low alloy steel covered electrodes. The material combinations to require weld material testing as listed in ND-2431 shall apply for this Standard Test Requirements option. The limitations and testing under this Standard Test option shall be in accordance with (a) through (f) below.

(a) Testing to the requirements of this subparagraph shall be limited to electrode classifications included in specifications SFA-5.1 or SFA-5.5.

(b) The test assembly required by SFA-5.1 or SFA-5.5, as applicable, shall be used for test coupon preparation, except that it shall be increased in size to obtain the number of C_v specimens required by ND-2331 when applicable.

(c) The welding of the test coupon shall conform to the requirements of the SFA specification for the classification of electrode being tested. Coupons shall be tested in the as-welded condition and also in the postweld heat treated condition. The PWHT temperatures shall be in accordance with Table ND-4622.1-1 for the applicable P-Number equivalent. The time at PWHT temperature shall be 8 hr (this qualifies PWHT of 10 hr or less). When the PWHT of the production weld exceeds 10 hr, or the PWHT temperature is other than that required above, the general test of ND-2431.1 shall be used.

(d) The tensile and C_v specimens shall be located and prepared in accordance with the requirements of SFA-5.1 or SFA-5.5 as applicable.

(e) One all-weld-metal tensile specimen shall be tested and shall meet the specified minimum tensile strength requirements of the SFA specification for the applicable electrode classification.

(f) The requirements of ND-2431.1(f) shall be applicable to the impact testing of this option.

[98]

ND-2432 Chemical Analysis Test

Chemical analysis of filler metal or weld deposits shall be made in accordance with ND-2420 and as required by the following subparagraphs.

**TABLE ND-2432.1-1
SAMPLING OF WELDING MATERIALS FOR
CHEMICAL ANALYSIS**

	GTAW/PAW	GMAW	All Other Processes
A-No. 8 filler metal	Filler metal or weld deposit	Weld deposit	Weld deposit
All other filler metal	Filler metal or weld deposit	Filler metal or weld deposit	Weld deposit

TABLE ND-2432.1-1 SAMPLING OF WELDING MATERIALS FOR CHEMICAL ANALYSIS

ND-2432.1 Test Method.

The chemical analysis test shall be performed in accordance with this subparagraph and Table ND-2432.1-1, and the results shall conform to ND-2432.2.

(a) A-No. 8 welding material to be used with GTAW and PAW processes and any other welding material to be used with any GTAW, PAW, or GMAW process shall have chemical analysis performed either on the filler metal or on a weld deposit made with the filler metal in accordance with (c) or (d) below.

(b) A-No. 8 welding material to be used with other than the GTAW and PAW processes and other welding material to be used with other than the GTAW, PAW, or GMAW process shall have chemical analysis performed on a weld deposit of the material or combination of materials being certified in accordance with (c) or (d) below. The removal of chemical analysis samples shall be from an undiluted weld deposit made in accordance with (c) below. As an

alternative, the deposit shall be made in accordance with (d) below for material that will be used for corrosion resistant overlay cladding. Where the Welding Procedure Specification or the welding material specification specifies percentage composition limits for analysis, it shall state that the specified limits apply for the filler metal analysis, the undiluted weld deposit analysis, or *in situ* cladding deposit analysis in conformance with the above required certification testing.

(c) The preparation of samples for chemical analysis of undiluted weld deposits shall comply with the method given in the applicable SFA specification. Where a weld deposit method is not provided by the SFA specification, the sample shall be removed from a weld

Page 27

pad, groove, or other test weld⁴ made using the welding process that will be followed when the welding material or combination of welding materials being certified is consumed. The weld for A-No. 8 material to be used with the GMAW or EGW process shall be made using the shielding gas composition specified in the Welding Procedure Specifications that will be followed when the material is consumed. The test sample for ESW shall be removed from the weld metal of the mechanical properties test coupon. Where a chemical analysis is required for a welding material which does not have a mechanical properties test requirement, a chemical analysis test coupon shall be prepared as required by ND-2431.1(c), except that heat treatment of the coupon is not required and the weld coupon thickness requirements of ND-2431.1(c) do not apply.

(d) The alternate method provided in (b) above for the preparation of samples for chemical analysis of welding material to be used for corrosion resistant overlay cladding shall require a test weld made in accordance with the essential variables of the Welding Procedure Specification that will be followed when the welding material is consumed. The test weld shall be made in conformance with the requirements of Section IX, QW-214.1. The removal of chemical analysis samples shall conform with QW-214.3 for the minimum thickness for which the Welding Procedure Specification is qualified.

ND-2432.2 Requirements for Chemical Analysis.

The chemical elements to be determined, the composition requirements of the weld metal, and the recording of results of the chemical analysis shall be in accordance with (a), (b), and (c) below.

(a) Welding material of ferrous alloy A-No. 8 (Section IX, QW-442) shall be analyzed for the elements listed in Table ND-2432.2-1 and any other elements specified in the welding material specification referenced by the Welding Procedure Specification.

⁴ The methods given in the Appendix of SFA 5.9, Specification for Corrosion-Resisting Chromium and Chromium-Nickel Steel Welding Rods and Bare Electrodes, shall be used to establish a welding and sampling method for the pad, groove, or other test weld to ensure that the weld deposit being sampled will be substantially free of base metal dilution.

(b) The chemical composition of the weld metal or filler metal shall conform to the welding material specification for elements having specified percentage composition limits. Where the Welding Procedure Specification contains a modification of the composition limits of SFA or other referenced welding material specifications, or provides limits for additional elements,

these composition limits of the Welding Procedure Specification shall apply for acceptability.

TABLE ND-2432.2-1 WELDING MATERIAL CHEMICAL ANALYSIS

Cr–Ni stainless materials	C, Cr, Mo, Ni, Mn, Si, Cb
---------------------------	------------------------------

TABLE ND-2432.2-1 WELDING MATERIAL CHEMICAL ANALYSIS

(c) The results of the chemical analysis shall be reported in accordance with NCA-3867. Elements listed in Table ND-2432.2-1 but not specified in the welding material specification or Welding Procedure Specification shall be reported for information only.

ND-2433 Delta Ferrite Determination

A determination of delta ferrite shall be performed on A-No. 8 weld material (Section IX, QW-442) backing filler metal (consumable inserts); bare electrode, rod, or wire filler metal; or weld metal, except that delta ferrite determinations are not required for SFA-5.4 Type 16-8-2, or A-No. 8 weld filler metal to be used for weld metal cladding.

ND-2433.1 Method.

Delta ferrite determinations of welding material, including consumable insert material, shall be made using a magnetic measuring instrument and weld deposits made in accordance with (b) below. Alternatively, the delta ferrite determinations for welding materials may be performed by the use of chemical analysis of ND-2432 in conjunction with Fig. ND-2433.1-1.

(a) Calibration of magnetic instruments shall conform to AWS-A4.2-91.

(b) The weld deposit for magnetic delta ferrite determination shall be made in accordance with ND-2432.1(c).

(c) A minimum of six ferrite readings shall be taken on the surface of the weld deposit. The readings obtained shall be averaged to a single Ferrite Number (FN).

ND-2433.2 Acceptance Standards.

The minimum acceptable delta ferrite shall be 5FN. The results of the delta ferrite determination shall be included in the Certified Material Test Report of ND-2130 or ND-4120.

ND-2440 STORAGE AND HANDLING OF WELDING MATERIAL

Suitable storage and handling of electrodes, flux, and other welding material shall be maintained. Precautions

Page 28

Page 29

shall be taken to minimize absorption of moisture by fluxes and cored, fabricated, and coated electrodes.

GENERAL NOTES:

- (a) The actual nitrogen content is preferred. If this is not available, the following applicable nitrogen value shall be used:
 - (1) GMAW welds-0.08%, except that when self shielding flux cored electrodes are used-0.12%.
 - (2) Welds made using other processes-0.06%.
- (b) This diagram is identical to the WRC-1992 Diagram, except that the solidification mode lines have been removed for ease of use.

FIG. ND-2433.1-1 DELTA FERRITE CONTENT

FIG. ND-2433.1-1 DELTA FERRITE CONTENT

ND-2500

ND-2510 PRESSURE RETAINING MATERIAL

Pressure retaining material shall be examined and repaired in accordance with the material specification and as otherwise required by this Subarticle. Pressure retaining material for ASME B16.34 Special Class category valves (NC-3513) shall be examined and repaired in accordance with the requirements therein and as otherwise required by this Subarticle. If the examination and repair requirements of this Subarticle either duplicate or exceed the ASME B16.34 requirements, then only the requirements of this Subarticle need to be met. Size exclusions of this Subarticle shall not be applied so as to reduce the examination requirements of ASME B16.34 for Special Class category valves.

ND-2530 EXAMINATION AND REPAIR OF PLATE

ND-2531 Required Examination

Plates shall be examined in accordance with the requirements of the material specification.

ND-2537 Time of Examination

Acceptance examinations shall be performed at the time of manufacture as required in (a) through (c) below.

(a) Examinations required by the material specification shall be performed at the time of manufacture as specified in the material specification.

(b) Radiographic examination of repair welds, when required, may be performed prior to any required postweld heat treatment.

(c) Magnetic particle or liquid penetrant examination of repair welds shall be performed after any required heat treatment, except for P-No. 1 material which may be examined before or after any required postweld heat treatment.

ND-2538 Elimination of Surface Defects

Surface defects shall be removed by grinding or machining, provided the requirements of (a) and (b) below are met.

(a) The depression, after defect elimination, is blended uniformly into the surrounding surface.

(b) If the elimination of the defect reduces the thickness of the section below the minimum required by the design, the material shall be repaired in accordance with ND-2539.

ND-2539 Repair by Welding

The Material Organization may repair by welding material from which defects have been removed, provided the depth of the repair cavity does not exceed one-third of the nominal thickness and the requirements of the following subparagraphs are met. Prior approval of the Certificate Holder shall be obtained for the repair of plates to be used in the manufacture of vessels.

ND-2539.1 Defect Removal.

The defect shall be removed or reduced to an imperfection of acceptable limit by suitable mechanical or thermal cutting or gouging methods and the cavity prepared for repair (ND-4211.1).

ND-2539.2 Qualification of Welding Procedures and Welders.

The welding procedure and welders or welding operators shall be qualified in accordance with the ND-4000 and Section IX.

ND-2539.3 Blending of Repaired Areas.

After repair, the surface shall be blended uniformly into the surrounding surface.

[98]

ND-2539.4 Examination of Repair Welds.

Each repair weld shall be examined by the magnetic particle method (ND-2545) or by the liquid penetrant method (ND-2546). In addition, when the depth of repair cavities exceeds the lesser of $\frac{3}{8}$ in. (10 mm), or 10% of the section thickness, the repair weld shall be radiographed in accordance with and to the applicable acceptance standards of ND-5320. The penetrameter shall be based upon the section thickness of the repaired area.

[98]

ND-2539.5 Heat Treatment After Repair.

The product shall be heat treated after repair in accordance with the heat treatment requirements of ND-4620.

ND-2539.6 Material Report Describing Defects and Repair.

Each defect repair that is required to be radiographed shall be described in the Certified Material Test Report. The Certified Material Test Report for each piece shall include a chart which shows the

Page 30

location and size of the prepared cavity, the welding material identification, the welding procedure, the heat treatment, and a report of the results of the examinations, including radiographic film.

ND-2540 EXAMINATION AND REPAIR OF FORGINGS AND BARS

ND-2541 Required Examination

Forgings and bars shall be examined in accordance with the requirements of the material specification except when magnetic particle or liquid penetrant examination is specifically required by the rules of this Subsection, in which case the examination shall conform to the requirements of ND-2545 or ND-2546, as applicable.

ND-2545 Magnetic Particle Examination

ND-2545.1 Examination Procedure.

The procedure for magnetic particle examination shall be in accordance with the methods of Section V, Article 7.

ND-2545.2 Evaluation of Indications

(a) Mechanical discontinuities at the surface are revealed by the retention of the examination medium. All indications are not necessarily defects, however, since certain metallurgical discontinuities and magnetic permeability variations may produce similar indications which are not relevant.

(b) Any indication in excess of the ND-2545.3 acceptance standards, which is believed to be nonrelevant, shall be reexamined by the same or other nondestructive examination methods to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. Nonrelevant indications which would mask defects are unacceptable.

(c) Relevant indications are indications which result from imperfections. Linear indications are indications in which the length is more than three times the width. Rounded indications are indications which are circular or elliptical with the length equal to or less than three times the width. Indications resulting from nonmetallic inclusions are not considered relevant indications.

ND-2545.3 Acceptance Standards

(a) Only imperfections producing indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Imperfections producing the following relevant indications are unacceptable:

(1) any linear indications greater than $\frac{1}{16}$ in. (1.6 mm) long for material less than $\frac{5}{8}$ in. (16 mm) thick, greater than $\frac{1}{8}$ in. (3.2 mm) long for material from $\frac{5}{8}$ in. (16 mm) thick to under 2 in. (51 mm) thick, and $\frac{3}{16}$ in. (4.8 mm) long for material 2 in. (51 mm) thick and greater;

(2) rounded indications with dimensions greater than $\frac{1}{8}$ in. (3.2 mm) for thicknesses $\frac{5}{8}$ in. (16 mm) and greater than $\frac{3}{16}$ in. (4.8 mm) for thicknesses $\frac{5}{8}$ in. (16 mm) and greater;

(3) four or more relevant indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more relevant indications in any 6 sq in. (3871 mm²) of area whose major dimension is no more than 6 in. (152 mm) with the dimensions taken in the most unfavorable location relative to the indications being evaluated.

ND-2546 Liquid Penetrant Examination

ND-2546.1 Examination Procedure.

The procedure for liquid penetrant examination shall be in accordance with the methods of Section V, Article 6.

ND-2546.2 Evaluation of Indications

(a) Mechanical discontinuities at the surface are revealed by bleeding out of the penetrant; however, localized surface discontinuities such as may occur from machining marks or surface conditions may produce similar indications which are not relevant.

(b) Any indication in excess of the ND-2546.3 acceptance standards which is believed to be nonrelevant shall be reexamined to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. Nonrelevant indications and broad areas of pigmentation which would mask defects are unacceptable.

(c) Relevant indications are indications which result from imperfections. Linear indications are indications in which the length is more than three times the width. Rounded indications are indications which are circular or elliptical with the length equal to or less than three times the width.

ND-2546.3 Acceptance Standards

(a) Only imperfections producing indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Imperfections producing the following relevant indications are unacceptable:

(1) any linear indications greater than $\frac{1}{16}$ in. (1.6 mm) long for materials less than $\frac{5}{8}$ in. (16 mm) thick, greater than $\frac{1}{8}$ in. (3.2 mm) long for material from $\frac{5}{8}$ in. (16 mm) thick to under 2 in. (51 mm) thick, and $\frac{3}{16}$ in. (4.8 mm) long for material 2 in. (51 mm) thick and greater;

(2) rounded indications with dimensions greater than $\frac{1}{8}$ in. (3.2 mm) for thicknesses less than $\frac{5}{8}$ in. (16 mm) and greater than $\frac{3}{16}$ in. (4.8 mm) for thicknesses $\frac{5}{8}$ in. (16 mm) and greater;

(3) four or more relevant indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more relevant indications in any 6 sq in. (3871 mm²) of area whose major dimension is no more than 6 in. (152 mm) with the dimensions taken in the most unfavorable location relative to the indications being evaluated.

ND-2547 Time of Examination

Acceptance examinations shall be performed as follows.

(a) Magnetic particle or liquid penetrant examination shall be performed in the finished condition.

(b) Forged and rolled bars which are to be bored or turned to form tubular products or fittings shall be examined after boring or turning, except for threaded or drilled holes.

ND-2548 Elimination of Surface Defects

(a) Unacceptable surface defects shall be removed by grinding or machining, provided the requirements of (1) through (4) below are met.

(1) The remaining thickness of the section is not reduced below that required by ND-3000.

(2) The depression, after defect elimination, is blended uniformly into the surrounding surface.

(3) After defect elimination, the area is reexamined by the magnetic particle method in accordance with ND-2545 or the liquid penetrant method in accordance with ND-2546 to ensure that the defect has been removed or the indication reduced to an acceptable size.

(4) Areas ground to remove oxide scale or other mechanically caused impressions for appearance or to facilitate proper ultrasonic testing need not be examined by the magnetic particle or liquid penetrant method.

(b) When the elimination of the defect reduces the thickness of the section below the minimum required to satisfy ND-3000, the product shall be repaired in accordance with ND-2549.

ND-2549 Repair by Welding

The Material Organization may repair by welding material from which defects have been removed, provided the requirements of the following subparagraphs are met.

ND-2549.1 Defect Removal.

The defect shall be removed or indication reduced to an acceptable size by suitable mechanical or thermal cutting or gouging methods and the cavity prepared for repair (ND-4211.1).

ND-2549.2 Qualification of Welding Procedures and Welders.

The welding procedure and welders or welding operators shall be qualified in accordance with ND-4000 and Section IX.

ND-2549.3 Blending of Repaired Areas.

After repair, the surface shall be blended uniformly into the surrounding surface.

ND-2549.4 Examination of Repair Welds.

Each repair weld shall be examined by the magnetic particle method (ND-2545) or by the liquid penetrant method (ND-2546). In addition, when the depth of the repair cavity exceeds the lesser of $\frac{3}{8}$ in. (10 mm) or 10% of the section thickness, the repair weld shall be radio graphed after repair in accordance with ND-5000. The penetrameter and the acceptance standards for radio graphic examination of repair welds shall be based on the section thickness at the repaired area.

ND-2549.5 Heat Treatment After Repairs.

The product shall be heat treated after repair in accordance with the heat treatment requirements of ND-4620.

ND-2549.6 Material Report Describing Defects and Repairs.

Each defect repair exceeding in depth the lesser of $\frac{3}{8}$ in. (10 mm) or 10% of the section thickness shall be described in the Certified Material Test Report. The Certified Material Test Report for each piece shall include a chart which shows the location and size of the prepared cavity, the welding material identification, the welding procedure, the heat treatment, and the examination results, including radiographic film.

ND-2550 EXAMINATION AND REPAIR OF SEAMLESS AND WELDED (WITHOUT FILLER METAL) TUBULAR PRODUCTS AND FITTINGS

ND-2551 Required Examination

Wrought seamless and welded (without filler metal) tubular products and fittings shall comply with the requirements of ND-2557, ND-2558, and ND-2559 in addition to the basic material specification.

Page 32

ND-2557 Time of Examination

(a) Products that are quenched and tempered shall be examined, as required, after the quenching and tempering heat treatment.

(b) Products that are not quenched and tempered shall receive the required examinations as follows.

(1) Magnetic particle or liquid penetrant examination of welds, including repair welds, shall be performed after final heat treatment, except that the examination may be performed prior to postweld heat treatment for P-No. 1 (Section IX of the Code) materials of 2 in. (51 mm) and less nominal thickness.

(2) Forgings and rolled bars which are to be bored and/or turned to form tubular parts or fittings shall be examined after boring and/or turning, except for threading. Fittings shall be examined after final forming.

(3) When surface examination is required all external surfaces and all accessible internal surfaces shall be examined except for bolt holes and threads.

ND-2558 Elimination of Surface Defects

Surface defects shall be removed by grinding or machining, provided the requirements of (a) through (c) below are met:

(a) the depression, after defect elimination, is blended uniformly into the surrounding surface;

(b) after defect elimination, the area is examined by the method which originally disclosed the defect to ensure that the defect has been removed or reduced to an imperfection of acceptable size.

(c) If the elimination of the defect reduces the thickness of the section below the minimum required to satisfy the rules of ND-3000, the product shall be repaired in accordance with ND-2559.

ND-2559 Repair by Welding

Repair of defects shall be in accordance with ND-2539, except repair by welding is not permitted on copper alloy and nickel alloy heat exchanger tubes.

ND-2560 EXAMINATION AND REPAIR OF TUBULAR PRODUCTS AND FITTINGS WELDED WITH FILLER METAL

ND-2561 Required Examinations

(a) Welded (with filler metal) tubular products such as pipe made in accordance with SA-134, SA-358, SA-409, SA-671, SA-672, and SA-691 and fittings made in accordance with the WPW grades of SA-234, SA-403, and SA-420 which are made by welding with filler metal shall be treated as materials; however, inspection by an Inspector and stamping with the NPT symbol shall be in accordance with Section III requirements. In addition to the NPT symbol, the numeral 3 shall be stamped below and outside the official Code symbol.

(b) In addition to the requirements of the material specification, tubular products shall comply with this Article.

(c) Weld joint efficiency factors listed in Tables 1A and 1B, Section II, Part D, shall apply.

(d) Tubular products and fittings which have been radiographed shall be marked to indicate that radiography has been performed. The radiographic film and a radiographic report showing film locations shall be provided with the Certified Material Test Report.

(e) The Authorized Inspector shall certify by signing the Partial Data Report Form NM-1 in accordance with NCA-5290.

ND-2567 Time of Examination

The time of examination shall be in accordance with the requirements of ND-2557.

ND-2568 Elimination of Surface Defects

Unacceptable surface defects shall be removed in accordance with the requirements of ND-2558.

ND-2569 Repair by Welding

When permitted by the basic material specification, base material defects shall be repair welded in accordance with the requirements of ND-2559. Repair welding of weld seam defects shall be in accordance with ND-4450.

ND-2570 EXAMINATION AND REPAIR OF STATICALLY AND CENTRIFUGALLY CAST PRODUCTS

In addition to the requirements of the material specification and of this Article, statically and centrifugally cast products shall comply with the following subparagraphs.

Page 33

ND-2571 Required Examinations

(a) Cast products shall be examined by volumetric and/or surface methods, including repairs, as required for the product form by Table ND-2571-1 Class 3 castings.

(b) For cast valves furnished to ASME B16.34 special class category, examination of castings, including procedure and acceptance requirements, shall be as required by ASME B16.34.

ND-2572 Time of Nondestructive Examination

ND-2572.1 Acceptance Examinations.

Acceptance examinations shall be performed at the time of manufacture as stipulated in the following and Table ND-2571-1.

(a) *Ultrasonic Examination.* Ultrasonic examination, if required, shall be performed at the same stage of manufacture as required for radiography.

(b) *Radiographic Examination.* Radiography may be performed prior to heat treatment and may be performed prior to or after finish machining at the following limiting thicknesses.

(1) For finished thicknesses under $2\frac{1}{2}$ in. (64 mm), castings shall be radiographed within 20% of the finished thickness when Type 2 radiographic film is used or within $\frac{1}{2}$ in. (13 mm) of the finished thickness when Type 1 radiographic film is used. The penetrometer and the acceptance reference radiographs shall be based on the finished thickness.

(2) For finished thickness from $2\frac{1}{2}$ in. (64 mm) up to 6 in. (152 mm), castings shall be radiographed within 20% of the finished thickness. The penetrometer and the acceptance reference radiographs shall be based on the finished thickness.

(3) For finished thicknesses over 6 in. (152 mm), castings shall be radiographed with $\frac{1}{2}$ in. (13 mm) or 15% of the finished thickness, whichever is greater. The penetrometer and the acceptance reference radiographs shall be based on the finished thickness.

(c) Radiography of castings for pumps and valves may be performed in as-cast or rough machined thickness exceeding the limits of (b)(1), (b)(2), or (b)(3) above, subject to the following conditions.

(1) When the thickness of the as-cast or rough machined section exceeds 2 in. (51 mm), acceptance shall be based on

reference radiographs for the next lesser thickness; e.g., if the section being radiographed exceeds $4\frac{1}{2}$ in. (114 mm), use reference radiographs of ASTM E 186-75 (reapproved 1979). The penetrameter shall be based on the thickness of the section being radiographed.

(2) When the thickness of the as-cast or rough machined section is 2 in. (51 mm) or less, the reference radiographs of ASTM E 446-78 shall be used and the penetrameter shall be based on the final section thickness.

(3) Weld ends for a minimum distance of t or $\frac{1}{2}$ in. (13 mm), whichever is less (where t is the design section thickness of the weld) from the final welding end shall be radiographed at a thickness within the limits given in (b)(1), (b)(2), or (b)(3) above as applicable. As an alternative, the weld ends may be radiographed in the as-cast or rough machined thickness in accordance with (c)(1) and (c)(2) above and the penetrameter shall be based on the final section thickness.

(d) *Magnetic Particle or Liquid Penetrant Examination.* Magnetic particle or liquid penetrant examination shall be performed after the final heat treatment required by the material specification. Repair weld areas shall be examined after postweld heat treatment when a postweld heat treatment is performed, except that repair welds in P-No. 1 (see Section IX of the Code) material 2 in. nominal thickness and less may be examined prior to postweld heat treatment. For cast products with machined surfaces, all finished machine surfaces, except threaded surfaces and small deep holes, shall also be examined by magnetic particle or liquid penetrant methods.

ND-2573 Provisions for Repair of Base Material by Welding

The Material Organization may repair, by welding, products from which defects have been removed, provided the requirements of this Article are met.

ND-2573.1 Defect Removal.

The defects shall be removed or reduced to an imperfection of acceptable size by suitable mechanical or thermal cutting or gouging methods, and the cavity prepared for repair. When thermal cutting is performed, consideration shall be given to preheating the material.

ND-2573.2 Repair by Welding.

The Material Organization may repair castings by welding after removing the material containing unacceptable defects. The depth of the repair is not limited. A cored hole or access hole may be closed by the Material Organization by welding in accordance with the requirements of this paragraph provided the hole is closed by filler metal only. If the hole is closed by welding in a metal insert, the welding shall be performed by a holder of a Certificate of Authorization in accordance with the requirements of the Code.

Page 34

Page 35

TABLE ND-2571-1 REQUIRED EXAMINATIONS

Nominal Pipe Size	Item	Applicable Special Requirements for Class 3 Castings
Inlet piping connections of 2 in. and less	Cast Pipe fittings, pump, and valves	None, except for ASME B16.34 special class category valves, which shall be in accordance with ND-2571(b).
	Cast pressure retaining material with a Quality Factor of 0.80, excluding pipe fittings, pumps, and valves	Visual examination required
	Cast pressure retaining material with a Quality Factor of 0.85, excluding pipe fittings, pumps, and valves	Magnetic particle or liquid penetrant examination shall be performed on all external surfaces and on all accessible internal surfaces.
	Cast pressure retaining material with a Quality Factor of 1.00, excluding pipe fittings, pumps, and valves	Radiographic or ultrasonic examination required; magnetic particle or liquid penetrant examination optional
	Repair welds	(a) When magnetic particle or liquid penetrant examination of the casting is required, each repair shall be examined by the magnetic particle method or by the liquid penetrant method. (b) When radiography of the casting is required, repair welds in cavities, the depth of which exceeds the lesser of $\frac{3}{8}$ in. or 10% of the section thickness, shall be radiographed in accordance with ND-2575. (c) When partial radiography of a casting is required, repairs located in an area of the casting which is not covered by radiography need only be examined by the magnetic particle method or by the liquid penetrant method.
Inlet piping connections over 2 in.	Cast valves	None, except for ASME B16.34 special class category valves, which shall be in accordance with ND-2571(b).
	Cast pressure retaining material with a Quality Factor of 0.80, excluding valves	Visual examination required
	Cast pressure retaining material with a Quality Factor of 0.85, excluding valves	Magnetic particle or liquid penetrant examination shall be performed on all external surfaces and on all accessible internal surfaces.
	Cast pressure retaining material with a Quality Factor of 1.00, excluding valves	Radiographic or ultrasonic examination required, magnetic particle or liquid penetrant examination optional
	Repair welds	(a) When magnetic particle or liquid penetrant examination of the casting is required, each repair weld shall be examined by the magnetic particle method or by the liquid penetrant method. (b) When radiography of the casting is required, repair welds in cavities, the depth of which exceeds the lesser of $\frac{3}{8}$ in. or 10% of the section thickness, shall be radiographed in accordance with ND-2575. (c) When partial radiography of a casting is required, repairs located in an area of the casting which is not covered by radiography need only be examined by the magnetic particle method or by the liquid penetrant method.

TABLE ND-2571-1 REQUIRED EXAMINATIONS

ND-2573.3 Qualification of Welding Procedures and Welders.

Each manufacturer is responsible for the welding done by his organization and shall establish the procedures and conduct the tests required by ND-4000 and by Section IX of the Code in order to qualify both the welding procedures and the performance of welders and welding operators who apply these procedures. He is also responsible for the welding performed by his subcontractors and shall assure himself that the subcontractors conduct the tests required by ND-4000 and by Section IX of the Code in order to qualify their welding procedures and the performance of their welders and welding operators.

ND-2573.4 Blending of Repaired Areas.

After repair, the surface shall be blended uniformly into the surrounding surface.

ND-2573.5 Examination of Repair Welds

(a) Each repair weld shall be examined by the magnetic particle method in accordance with the requirements of ND-2577 or by the liquid penetrant method in accordance with the requirements of ND-2576. In addition, when radiography is specified in the order for the original casting, repair cavities, the depth of which exceeds the lesser or $\frac{3}{8}$ in. or 10% of the nominal wall thickness, shall be radiographed after repair, except that weld slag, including elongated slag, shall be considered as inclusions under Category B of the applicable reference radiographs. The total area of all inclusions, including slag inclusions, shall not exceed the limits of the applicable severity level of Category B of the reference radiographs. The penetrometer and the acceptance standards for radiographic examination of repair welds shall be based on the actual section thickness at the repaired area.

(b) Examination of repair welds in P-No. 1 and P-No. 8 material is not required for pumps and valves with inlet piping connections NPS 2 and less.

ND-2573.6 Heat Treatment After Repairs.

The material shall be heat treated after repair in accordance with the heat treatment requirements of ND-4620, except that the heating and cooling rate limitations of ND-4623 do not apply.

ND-2573.7 Elimination of Surface Defects.

Surface defects shall be removed by grinding or machining, provided the requirements of (a) through (c) below are met:

(a) the depression, after defect elimination, is blended uniformly into the surrounding surface;

(b) after defect elimination, the area is reexamined by the magnetic particle method in accordance with ND-2577 or the liquid penetrant method in accordance with ND-2576 to ensure that the defect has been removed or reduced to an imperfection of acceptable size;

(c) if the elimination of the defect reduces the section thickness below the minimum required by the specification or drawing, the casting shall be repaired in accordance with ND-2539.

ND-2573.8 Material Report Describing Defects and Repairs.

Each defect repair exceeding in depth the lesser of $\frac{3}{8}$ in. or 10% of the nominal wall thickness shall be described in the Certified Material Test Report. The Certified Material Test Report for each piece shall include a chart that shows the location and size of the prepared cavity, the welding material identification, the welding procedure, the heat treatment, and the examination results, including radiographic film, when radiography is specified in the order for the original casting.

ND-2574 Ultrasonic Examination of Ferritic Steel Castings

Ultrasonic examination shall be performed in accordance with T-541.4 of Article 5 of Section V. Each manufacturer shall certify that the procedure is in accordance with the requirements of ND-2574 and shall make the procedure available for approval upon request.

ND-2574.1 Acceptance Standards

(a) The Quality Levels of SA-609 as shown in Section V shall apply for the casting thicknesses indicated:

- (1) Quality Level 1 for thicknesses up to 2 in.;
- (2) Quality Level 3 for thicknesses 2 to 4 in.;
- (3) Quality Level 4 for thicknesses greater than 4 in.

(b) In addition to the Quality Level requirements stated in (a) above, the requirements in (1) through (5) below shall apply for both straight beam and angle beam examination.

(1) Areas giving indications exceeding the Amplitude Reference Line with any dimension longer than those specified in the following tabulation are unacceptable:

Page 36

UT Quality Level	Longest Dimension of Area ⁵⁶⁷
1	1.5 in.
2	2.0 in.
3	2.5 in.
4	3.0 in.

(2) Quality Level 1 shall apply for the volume of castings within 1 in. of the surface regardless of the overall thickness.

(3) Discontinuities indicated to have a change in depth equal to or greater than one-half the wall thickness or 1 in. (whichever is less) are unacceptable.

(4) Two or more imperfections producing indications in the same plane with amplitudes exceeding the Amplitude Reference Line and separated by a distance less than the longest dimension of the larger of the adjacent indications are unacceptable if they cannot be encompassed within an area less than that of the Quality Level specified in (b)(1) above.

(5) Two or more imperfections producing indications greater than permitted for Quality Level 1 for castings less than 2 in. in thickness, greater than permitted for Quality Level 2 for thicknesses 2 in. through 4 in., and greater than permitted for Quality Level 3 for thicknesses greater than 4 in., separated by a distance less than the longest dimension of the larger of the adjacent indications are unacceptable, if they can not be encompassed in an area less than that of the Quality Level requirements stated in (a) above.

ND-2575 Radiographic Examination

ND-2575.1 Examination.

Cast pressure retaining materials shall be examined by the radiographic method when specified in the order for the original castings, except that cast ferritic steels may be examined by either radiographic or ultrasonic methods, or a combination of both methods. Castings or sections of castings that have coarse grains or configurations that do not yield meaningful examination results by ultrasonic methods shall be examined by the radiographic method.

⁵ The areas for the Ultrasonic Quality Levels in SA-609 refer to the surface area on the casting over which a continuous indication exceeding the transfer corrected distance amplitude curve is maintained.

⁶ Areas are to be measured from dimensions of the movement of the search unit, using the center of the search unit as the reference point.

⁷ In certain castings, because of very long metal path distances or curvature of the examination surfaces, the surface area over which a given discontinuity is detected may be considerably larger or

smaller than the actual area of the discontinuity in the casting; in such cases, other criteria which incorporate a consideration of beam angles or beam spread must be used for realistic evaluation of the discontinuity.

ND-2575.2 Extent.

Radiographic examination shall be performed on pressure retaining castings such as vessel heads and flanges, valve bodies, bonnets and disks, pump casings and covers, and piping and fittings. The extent of radiographic coverage shall be of the maximum feasible volume and, when the shape of the casting precludes complete coverage, the coverage shall be at least as exemplified in the typical sketches as shown in Fig. ND-2575.2-1.

ND-2575.3 Examination Procedure.

The radiographic examination shall be performed in accordance with Article 2 of Section V, with the following modifications.

(a) *Film Selection.* Only Types 1, 2, and 3 are permitted.

(b) *Radiographic Density.* The transmitted film density through the radiographic image of the body of the appropriate penetrameter and the area of interest shall be 1.3 minimum for single film viewing. For composite viewing of multiple film exposures, each film of the composite set shall have a minimum density of 1.0. The maximum density shall be 4.0 for either single or composite viewing. A tolerance of 0.05 in density is allowed for variations between densitometer readings.

(c) The requirements of T-274 and T-285 of Article 2 of Section V need not be met.

(d) *Image Quality Indicator (IQI) Design.* Penetrameters shall be manufactured and identified in accordance with the requirements or alternatives allowed in SE-142 and Appendices.

(e) *Image Quality Indicator (IQI) Selection.* The radio graphic quality level shall be 2-4 T for section thicknesses up to and including $\frac{3}{4}$ in. and 2-2 T for section thicknesses greater than $\frac{3}{4}$ in. Radiographic quality is defined in Note 2 of SE-94.

(f) When radiographing weld ends of cast valves, NPS 4 and less, double-wall radiography may be used subject to the conditions of (1) and (2) below.

(1) The penetrameter thickness shall be based on the design section thickness of the double wall, excluding the weld preparation lip.

(2) Acceptance standards shall be based on nominal single-wall thickness.

ND-2575.4 Procedure Requirements.

Radiographic examination shall be performed in accordance with a written procedure. Each manufacturer shall certify that the procedure is in accordance with the requirements of NB-2575. The procedure shall be available for the interpretation of the films and shall be submitted together with the radiographs. Each procedure shall include at least the following information:

(a) the type of material to be radiographed;

Page 37

(b)

Page 39

Pages 38-38

(a) Typical Volute-Type Pump Case

GENERAL NOTES:

- (a) Radiographic examination areas shall be indicated by a circle at each change of direction. The examination symbol for radiography shall be indicated as RT.
- (b) For nondestructive examination areas of revolution, the area shall be indicated by the examine-all-around symbol: — RT — ⌀
- (c) The sketches are typical and are to be used as a guide for minimum required coverage. Even though a sketch may be titled, "pump" or "valve," the coverage shown by the configurations may be applied interchangeably.

(b) Typical Diffuser-Type Pump Case

(c) Typical Diffuser-Type Pump Case Detail

(g) Typical Globe Valve

FIG. ND-2575.2-1 TYPICAL PRESSURE RETAINING PARTS OF PUMPS AND VALVES (CONT'D)

FIG. ND-2575.2-1 TYPICAL PRESSURE RETAINING PARTS OF PUMPS AND VALVES (CONT'D)

(b) the material thickness ranges to be radiographed;

(c) the type of radiation source, actual or maximum source size or focal spot, and X-ray equipment voltage rating and manufacturer. The equipment manufacturer's or supplier's publications, such as technical manuals, decay curves, or written statements documenting the actual or maximum source size or focal spot, shall be acceptable as source size verification. For X-ray machines 320 KV and less, the focal spot size may be determined by the pinhole method⁸

(d) type and thickness of intensifying screens and filters;

(e) minimum source-to-film distance.

ND-2575.5 Radiographic Setup Information.

To aid in proper interpretation of radiographs, details of the radiographic examination setup used shall accompany each group of radiographs. As a minimum, the information shall include:

(a) film brand and the type and number of films in the cassette;

(b) for multiple film technique, state whether viewing is to be single or superimposed;

(c) blocking or masking technique, if used;

(d) isotope or X-ray voltage used;

(e) source to film distance used;

(f) distance between film and object when film/cassette is not in contact with object;

(g) geometric arrangement for the radiograph(s) (sketch);

(h) orientation of location markers;

(i) description of how internal markers, when used, locate area of interest;

(j) Location markers, such as lead numbers or letters, which shall appear as radiographic images on the film, shall be permanently stamped on the surface of the casting being radiographed in a manner permitting the area of interest on a radiograph to be accurately located on the casting and providing evidence on the radiograph that the extent of coverage required by ND-2575.2 has been obtained. On castings or sections of castings where stamping is not feasible, the radiographic procedure shall so state, in which case a radiographic film location map shall be provided.

⁸ Nondestructive Testing Handbook, Volume I, First Edition, pp. 14.32, 14.33, "Measuring Focal-Spot Size." Also, pp. 20, 21 of Radiography in Modern Industry, Fourth Edition.

ND-2575.6 Acceptance Criteria.

Castings shall meet the acceptance requirements of Severity Level 2 of ASTM E 446-72, E 446-75, or E 446-78, Reference Radiographs for Steel Castings up to 2 in. in Thickness, ASTM E 186-67, E 186-73, or E 186-75, Reference Radiographs for Heavy-Walled (2 to 4½ in.) Steel Castings, or ASTM E 280-68, E 280-72, or E 280-75, Reference Radiographs for Heavy Walled (4½ to 12 in.) Steel Castings, as applicable for the thickness being radiographed, except Category D, E, F, or G defects are not acceptable. The requirements of ASTM E 280-68, E 280-72, or E 280-75 shall apply for castings over 12 in. in thickness.

ND-2576 Liquid Penetrant Examination

(a) Castings shall be examined, if required, on all accessible surfaces by the liquid penetrant method in accordance with Section V of the Code.

(b) *Evaluation of Indications.* All indications shall be evaluated in terms of the acceptance standards. Mechanical discontinuities intersecting the surface are indicated by bleeding out of the penetrant; however, localized surface discontinuities as may occur from machining marks, scale, or dents may produce indications which are not relevant. Any indication in excess of the acceptance standards believed to be nonrelevant shall be reexamined to verify whether actual

defects are present. Surface conditioning may precede the reexamination. Nonrelevant indications and broad areas of pigmentation that would mask indications of defects are unacceptable. Relevant indications are those which result from imperfections and have a major dimension greater than $\frac{1}{16}$ in. Linear indications are those whose length is more than three times the width. Rounded indications are those which are circular or elliptical with the length less than three times the width.

(c) *Acceptance Standards.* The following relevant indications are unacceptable:

(1) linear indications greater than $\frac{1}{16}$ in. (1.6 mm) long for materials less than $\frac{5}{8}$ in. (16 mm) thick, greater than $\frac{1}{8}$ in. (3.2 mm) long for materials from $\frac{5}{8}$ in. (16 mm) thick to under 2 in. (51 mm) thick, and $\frac{3}{16}$ in. (4.8 mm) long for materials 2 in. (51 mm) thick and greater;

(2) rounded indications with dimensions greater than $\frac{1}{8}$ in. (3.2 mm) for thicknesses less than $\frac{5}{8}$ in. (16 mm) and greater than $\frac{3}{16}$ in. (4.8 mm) for thicknesses $\frac{5}{8}$ in. (16 mm) and greater;

(3) four or more indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more indications in any 6 sq in. (3871 mm²) of surface with the major dimension of this area not to exceed 6 in. (152 mm) taken in the most unfavorable orientation relative to the indications being evaluated.

Page 40

ND-2577 Magnetic Particle Examination (for Ferritic Steel Products Only)

(a) Castings of magnetic material shall be examined, if required, on all accessible surfaces by a magnetic particle method in accordance with Section V of the Code.

(b) *Evaluation of Indications.* All indications shall be evaluated in terms of the acceptance standards. Mechanical discontinuities intersecting the surface are indicated by retention of the examination medium. All indications are not necessarily defects since certain metallurgical discontinuities and magnetic permeability variations may produce indications that are not relevant. Any indication in excess of the acceptance standards believed to be nonrelevant shall be reexamined to verify whether actual defects are present. Nonrelevant indications which would mask indications of defects are unacceptable. Surface conditioning may precede the reexamination. Relevant indications are those which result from imperfections and have a major dimension greater than $\frac{1}{16}$ in. (1.6 mm). Linear indications are those whose length is more than three times the width. Rounded indications are those which are circular or elliptical with the length less than three times the width.

(c) *Acceptance Standards.* The following relevant indications are unacceptable:

(1) linear indications greater than $\frac{1}{16}$ in. (1.6 mm) long for materials less than $\frac{5}{8}$ in. (16 mm) thick, greater than $\frac{1}{8}$ in. (3.2 mm) long for materials from $\frac{5}{8}$ in. (16 mm) thick to under 2 in. (51 mm) thick, and $\frac{3}{16}$ in. (4.8 mm) long for materials 2 in. (51 mm) thick and greater;

(2) rounded indications with dimensions greater than $\frac{1}{8}$ in. (3.2 mm) for thicknesses less than $\frac{5}{8}$ in. (16 mm) and greater than $\frac{3}{16}$ in. (4.8 mm) for thicknesses $\frac{5}{8}$ in. (16 mm) and greater;

(3) four or more relevant indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more relevant indications in any 6 sq in. (3871 mm²) of surface with the major dimension of this area not to exceed 6 in. (152 mm) taken in the most unfavorable orientation relative to the indications being evaluated.

ND-2580 EXAMINATION OF BOLTS, STUDS, AND NUTS

ND-2581 Requirements

All bolting materials shall be visually examined in accordance with ND-2582.

ND-2582 Visual Examination

Visual examination shall be applied to the areas of threads, shanks, and heads of final machined parts. Harmful

discontinuities such as laps, seams, or cracks that would be detrimental to the intended service are unacceptable.

ND-2600 MATERIAL ORGANIZATIONS' QUALITY SYSTEM PROGRAMS

ND-2610 DOCUMENTATION AND MAINTENANCE OF QUALITY SYSTEM PROGRAMS

(a) Except as provided in (b) below, Material Organizations shall have a Quality System Program or an Identification and Verification Program, as applicable, which meets the requirements of NCA-3800.

(b) The requirements of NCA-3862 shall be met as required by ND-2130. The other requirements of NCA-3800 need not be used by Material Organizations for small products, as defined in (c) below, for brazing material, and for material which is allowed by this Subsection to be furnished with a Certificate of Compliance. For these products, the Certificate Holder's Quality Control System (NCA-8120) shall include measures to provide assurance that the material is furnished in accordance with the material specification and with the applicable requirements of this Subsection.

(c) For the purpose of this paragraph, small products are defined as given in (1) through (5) below:

- (1) pipe, tube (except heat exchanger tube), pipe fittings, and flanges NPS 2 (DN 50) and less;
- (2) bolting material, including studs, nuts, and bolts of 1 in. (25 mm) nominal diameter and less;
- (3) bars with a nominal cross-sectional area of 1 sq in. (645 mm²) and less;
- (4) material for pumps and valves with inlet pipe connections of NPS 2 (DN 50) and less;
- (5) material exempted by ND-2121(c).

ND-2700 DIMENSIONAL STANDARDS

Dimensions of standard items shall comply with the standards and specifications of Table ND-3132-1.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 ND-3000

ARTICLE ND-3000 DESIGN

Page 41

Page 42

ND-3100 GENERAL DESIGN

ND-3110 LOADING CRITERIA

ND-3111 Loading Conditions

The loadings that shall be taken into account in designing a component shall include, but are not limited to, those in (a) through (h) below:

- (a) internal and external pressure;
- (b) impact forces caused by either external or internal conditions;
- (c) impact loads, including rapidly fluctuating pressures;
- (d) weight of the component and normal contents under operating or test conditions, including additional pressure due to static and dynamic head of liquids;
- (e) superimposed loads such as other components, operating equipment, insulation, corrosion resistant or erosion

resistant linings, and piping;

(f) wind loads, snow loads, vibrations, and earth quake loads where specified;

(g) reactions of supporting lugs, rings, saddles, or other types of supports;

(h) temperature effects.

ND-3112 Design Loadings

The Design Loadings shall be established in accordance with NCA-2142.1 and the following subparagraphs.

ND-3112.1 Design Pressure.

The specified internal and external Design Pressures to be used in this Subsection shall be established in accordance with NCA-2142.1(a).

ND-3112.2 Design Temperature.

The specified Design Temperature shall be established in accordance with NCA-2142.1(b). It shall be used in conjunction with Design Pressure. If necessary, the metal temperature shall be determined by computation using accepted heat transfer procedures or by measurement from equipment in service under equivalent operating conditions.

In no case shall the temperature at the surface of the metal exceed the maximum temperature listed in Tables 1A and 1B, Section II, Part D, Subpart 1 nor exceed the temperature limitations specified elsewhere in this Subsection.

ND-3112.3 Design Mechanical Loads.

The specified Design Mechanical Loads shall be established in accordance with NCA-2142.1(c). They shall be used in conjunction with the Design Pressure.

ND-3112.4 Design Allowable Stress Values

(a) Allowable stresses for design for material are listed in Tables 1A and 1B, Section II, Part D, Subpart 1. The material shall not be used at metal and design temperatures above those for which stress values are given. The values in the Tables may be interpolated for intermediate temperatures.

(b) The maximum allowable compressive stress to be used in the design of cylindrical shells subjected to loadings that produce longitudinal compressive stress in the shell shall be the smaller of the following values:

(1) the maximum allowable tensile stress value permitted in (a) above;

(2) the value of the factor B determined from ND-3133.6(b).

(c) The wall thickness of a component computed by the rules of this Subsection shall be determined so that the general membrane stress, due to any combination of mechanical loadings listed in ND-3111 which are expected to occur simultaneously during a condition of loading for which Service Level A is designated for the component, does not exceed¹ the maximum allowable stress value permitted at the Design Temperature unless specifically permitted in other paragraphs of this Subsection. These allowable stress values may be interpolated for intermediate Design Temperatures.

¹ It is recognized that high localized and secondary stresses may exist in components designed and fabricated in accordance with the rules of this Subsection; however, insofar as practical, design rules for details have been written to hold such stresses at a safe level consistent with experience.

(d) When welding or brazing is performed on nonferrous material having increased tensile strength produced by hot or cold working, the allowable stress value for the material in the annealed condition shall be used for the joint design. One piece heads and seamless shells may be designed on the basis of the actual temper of the material.

(e) When welding or brazing is done on nonferrous material having increased tensile strength produced by heat treatment, the allowable stress value for the material in the annealed condition shall be used for the joint design unless the stress values for welded construction are given in the Tables 1A and 2B, Section II, Part D, Subpart 1 or unless the

finished construction is subjected to the same heat treatment as that which produced the temper in the *as-received* material, provided the welded joint and the base metal are similarly affected by the heat treatment.

ND-3113 Service Conditions

(a) Each condition to which the components may be subjected shall be classified in accordance with NCA-2142(b) designated in the Design Specifications in such detail as will provide a complete basis for design in accordance with this Article.

(b) When any Level B, Level C, or Level D Conditions are specified in the Design Specifications, they shall be evaluated in accordance with NCA-2140 and in compliance with the applicable design rules and stress limits of this Article.

ND-3115 Casting Quality Factors

A casting quality factor shall be applied to the allowable stress values for cast material given in Tables 1A, 1B, 2B, and 3, Section II, Part D, Subpart 1.

ND-3120 SPECIAL CONSIDERATIONS

ND-3121 Corrosion

(a) Materials subject to thinning by corrosion, erosion, mechanical, or other environmental effects shall have provision made for these effects in the Design Specifications by indicating the increase in the thickness of the material over that determined by the design equations. Other suitable methods of protection may be used. Material added for these purposes need not be of the same thickness for all areas of the component if different rates of attack are expected for the various areas.

(b) Except as required in (c) below, no additional thickness need be provided when previous experience in like service has shown that corrosion does not occur or is of only a superficial nature.

(c) Vessels constructed of materials listed in Tables 1A and 2B, Section II, Part D, Subpart 1 with a required minimum thickness of less than $\frac{1}{4}$ in. (6 mm) that are to be used in compressed air service, steam service, or water service shall be provided with a corrosion allowance on the metal surface in contact with such substance of not less than one-sixth of the calculated plate thickness.

(d) Telltale holes may be used to provide some positive indication when the thickness has been reduced to a minimum. When telltale holes are provided, they shall be at least $\frac{3}{16}$ in. (4.8 mm) in diameter and have a depth not less than 80% of the thickness required for a section of like dimensions. These holes shall be provided in the surface opposite to that where deterioration is expected.

ND-3122 Cladding

The rules of this paragraph apply to the design of clad components constructed of material permitted in Tables 1A and 2B, Section II, Part D, Subpart 1.

ND-3122.1 Stresses.

No structural strength shall be attributed to the cladding.

ND-3122.2 Design Dimensions.

The dimensions given in (a) and (b) below shall be used in the design of the component.

(a) For components subjected to internal pressure, the inside diameter shall be taken at the nominal inner face of the cladding.

(b) For components subjected to external pressure, the outside diameter shall be taken at the outer face of the base metal.

ND-3123 Welds Between Dissimilar Metals

In satisfying the requirements of this Article, caution shall be exercised in construction involving dissimilar metals having different chemical compositions, mechanical properties, and coefficients of thermal expansion in order to avoid difficulties in service.

ND-3125 Configuration

Accessibility to permit the examinations required by the Edition and Addenda of Section XI as specified in the Design Specification for the component shall be provided in the design of the component.

Page 55

ND-3130 GENERAL DESIGN RULES

ND-3131 General Requirements

The design shall be such that the design rules of this Article are satisfied for all configurations and loadings using the maximum allowable stress values S of Tables 1A, 1B, and 3, Section II, Part D, Subpart 1 in the various equations and including the use of the standard products listed in Table ND-3132-1.

ND-3131.1 Design Reports.

The N Certificate Holder is required to provide a Design Report as part of the responsibility for achieving structural integrity of the component. The Design Report shall be certified when required by NCA-3550.

ND-3131.2 Proof Tests to Establish Maximum Allowable Pressure.

When the configuration of a component is such that the stresses resulting from internal or external pressure cannot be determined with adequate accuracy by the rules of this Article, the maximum allowable pressure shall be determined by proof testing in accordance with the rules of ND-6900, except for piping as otherwise provided in this Article.

ND-3132 Dimensional Standards for Standard Products

Dimensions of standard products shall comply with the standards and specifications listed in Table ND-3132-1 when the standard or specification is referenced in the specific design Subarticle. However, compliance with these standards does not replace or eliminate the requirements for stress analysis when called for by the design Subarticle for a specific component.

ND-3133 Components Under External Pressure

ND-3133.1 General.

Rules are given in this paragraph for determining the thickness under external pressure loading in spherical shells, conical sections, cylindrical shells with or without stiffening rings, formed heads, and tubular products consisting of pipes, tubes, and fittings. Charts for determining the stresses in shells and hemispherical heads are given in Section II, Part D, Subpart 3.

ND-3133.2 Nomenclature.

The symbols used in this paragraph are defined as follows:

A	= factor determined from Fig. G, Section II, Part D, Subpart 3 and used to enter the applicable material chart in Section II, Part D, Subpart 3. For the case of cylinders having D_o/T values less than 10, see ND-3133.3(b). Also, factor determined from the applicable chart in Section II, Part D, Subpart 3 for the material used in a stiffening ring, corresponding to the factor B
-----	---

and the design metal temperature for the shell under consideration.

A_s	= cross-sectional area of a stiffening ring, sq in.
B	= factor determined from the applicable chart in Section II, Part D, Subpart 3 for the material used in a shell or stiffening ring at the design metal temperature, psi
D_o	= outside diameter of the cylindrical shell course, head skirt, or tube under consideration, in.
D_s	= outside diameter at small end of conical section under consideration, in.
D_L	= outside diameter at large end of conical section under consideration, in.
$D_o/2h_o$	= ratio of the major to the minor axis of ellipsoidal heads, which equals the outside diameter of the head skirt divided by twice the outside height of the head (see Table ND-3332.2-1)
E	= modulus of elasticity of material at Design Temperature, psi. For external pressure and axial compression design in accordance with this Section the modulus of elasticity to be used shall be taken from the applicable materials chart in Section II, Part D, Subpart 3. (Interpolation may be made between lines for intermediate temperatures.) The modulus of elasticity values shown in Section II, Part D, Subpart 3 for material groups may differ from those values listed in Table TM, Section II, Part D, Subpart 2 for specific materials. Section II, Part D, Subpart 3 values shall be applied only to external pressure and axial compression design.
h_o	= one-half of the length of the outside minor axis of the ellipsoidal head, or the outside height of the ellipsoidal head measured from the tangent line (head-bend line), in.
I	= available moment of inertia of the stiffening ring about its neutral axis, parallel to the axis of the shell, in. ⁴
I'	= available moment of inertia of the combined ring-shell cross section about its neutral axis, parallel to the shell, in. ⁴ The width of the shell which is taken as contributing to the combined moment of inertia shall not be greater than $1.10\sqrt{D_o \bar{T}_n}$ and shall be taken as lying one-half on each side of the centroid of the ring. Portions of shell plates shall not be considered as contributing to more than one stiffening ring.

I'_s	= required moment of inertia of the combined ring-shell section about its neutral axis parallel to the axis of the shell, in. ⁴
I_s	= required moment of inertia of the stiffening ring about its neutral axis parallel to the axis of the shell, in. ⁴

K_1	= factor depending on the ellipsoidal head proportions $D_o/2h_o$ (see Table ND-3332.2-1)
L	= total length of a tube between tubesheets, or the design length of a vessel section, taken as the largest of the following: (1) the distance between head tangent lines plus one-third of the depth of each head if there are no stiffening rings (excluding conical heads and sections); (2) the distance between cone-to-cylinder junctions for vessels with a cone or conical head if there are no stiffening rings; (3) the greatest center-to-center distance between any two adjacent stiffening rings; (4) the distance from the center of the first stiffening ring to the head tangent line plus one-third of the depth of the head
	Page 57
	(excluding conical heads and sections), all measured parallel to the axis of the vessel;
	(5) the distance from the first stiffening ring in the cylinder to the cone-to-cylinder junction; or
	(6) the axial length of the conical heads and sections as given in ND-3133.4(e), and Appendix XXII.
L_e	= equivalent length of conical section, in. $= (L/2)(1 + D_s/D_L)$
L_s	= one-half of the distance, in., from the center line of the stiffening ring to the next line of support on one side, plus one-half of the center line distance to the next line of support on the other side of the stiffening ring, both measured parallel to the axis of the component. A line of support is: (1) a stiffening ring that meets the requirements of this paragraph; (2) a circumferential line on a head at one-third the depth of the head from the head tangent line; (3) a circumferential connection to a jacket for a jacketed section of a cylindrical shell; or (4) a cone-to-cylinder junction.
P	= external Design Pressure, psi (gage or absolute, as required)
P_a	= allowable external pressure, psi (gage or absolute, as required)
R	= inside radius of cylindrical shell or tubular product in the corroded condition, in.
R_o	= for hemispherical heads, the outside radius in the corroded condition, in. = for ellipsoidal heads, the equivalent outside spherical radius taken as $K_1 D_o$ in the corroded condition, in. = for torispherical heads, the outside radius of the crown portion of the head in the corroded condition, in.

S	= the lesser of twice the allowable stress at design metal temperature from Tables 1A and 1B, Section II, Part D, Subpart 1, or 0.9 times the tabulated yield strength at design metal temperature from Tables Y-1, Section II, Part D, Subpart 2, psi
T	= minimum required thickness of cylindrical shell or tube, spherical shell, or formed head after forming, in the corroded condition, in.
T_e	= effective thickness of conical section, in. = $T \cos \alpha$
T_n	= nominal thickness used, less corrosion allowance, of a cylindrical shell or tube, in.
α	= one-half the apex angle in conical heads and sections, deg

TABLE ND-3132-1 DIMENSIONAL STANDARDS

ND-3133.3 Cylindrical Shells and Tubular Products.

The thickness of cylinders under external pressure shall be as determined by the procedure given in (a) or (b) below.

(a) Cylinders having D_o/T values ≥ 10 :

Step 1: Assume a value for T and determine the ratios L/D_o and D_o/T .

Step 2: Enter Fig. G, Section II, Part D, Subpart 3 at the value of L/D_o determined in Step 1. For values of L/D_o greater than 50, enter the chart at a value of $L/D_o = 50$. For values of $L/D_o < 0.05$, enter the chart at a value of L/D_o of 0.05.

Step 3: Move horizontally to the line for the value of D_o/T determined in Step 1. Interpolation may be made for intermediate values of D_o/T . From this point of intersection move vertically downward to determine the value of factor A .

Step 4: Using the value of A calculated in Step 3, enter the applicable material chart in Section II, Part D, Subpart 3 for the material under consideration. Move vertically to an intersection with the material/temperature line for the Design Temperature. Interpolation may be made between lines for intermediate temperatures. In cases where the value of A falls to the right of the end of the material/temperature line, assume an intersection with the horizontal projection of the upper end of the material/temperature line. For values of A falling to the left of the material/temperature line, see Step 7.

Step 5: From the intersection obtained in Step 4, move horizontally to the right and read the value of B .

Step 6: Using this value of B , calculate the value of the maximum allowable external pressure P_a using the following equation:

$$P_a = \frac{4B}{3(D_o/T)}$$

Step 7: For values of A falling to the left of the applicable material/temperature line, the value of P_a can be calculated using the following equation:

$$P_a = \frac{2AE}{3(D_o/T)}$$

Step 8: Compare P_a with P . If P_a is smaller than P , select a larger value for T and repeat the design procedure until a value of P_a is obtained that is equal to or greater than P .

(b) Cylinders having D_o/T values < 10:

Step 1: Using the same procedure as given in (a) above, obtain the value of B . For values of D_o/T less than 4, the value of factor A can be calculated using the following equation:

$$A = \frac{1.1}{(D_o/T)^2}$$

For values of A greater than 0.10, use a value of 0.10.

Step 2: Using the value of B obtained in Step 1, calculate a value P_{a1} using the following equation:

$$P_{a1} = \left[\frac{2.167}{(D_o/T)} - 0.0833 \right] B$$

Step 3: Calculate a value P_{a2} using the following equation:

$$P_{a2} = \frac{2S'}{(D_o/T)} \left[1 - \frac{1}{(D_o/T)} \right]$$

Step 4: The smaller of the values of P_{a1} calculated in Step 2 or P_{a2} calculated in Step 3 shall be used for the maximum allowable external pressure P_a . Compare P_a with P . If P_a is smaller than P , select a larger value for T and repeat the design procedure until a value for P_a is obtained that is equal to or greater than P .

ND-3133.4 Spherical Shells and Formed Heads

(a) *Spherical Shells*. The minimum required thickness of a spherical shell under external pressure, either seamless or of built-up construction with butt joints, shall be determined by the procedure given in Steps 1 through 6.

Step 1: Assume a value for T and calculate the value of factor A using the following equation:

$$A = \frac{0.125}{(R_o/T)}$$

Step 2: Using the value of A calculated in Step 1, enter the applicable material chart in Section II, Part D, Subpart 3 for the material under consideration. Move vertically to an intersection with the material/temperature line for the Design Temperature. Interpolation may be made between lines for intermediate temperatures. In cases where the value at A falls to the right of the end of the material/temperature line, assume an intersection with the horizontal projection of the upper end of the material/temperature line. For values at A falling to the left of the material/temperature line, see Step 5.

Step 3: From the intersection obtained in Step 2, move horizontally to the right and read the value of factor B .

Step 4: Using the value of B obtained in Step 3, calculate the value of the maximum allowable external pressure P_a using the following equation:

$$P_a = \frac{B}{(R_o/T)}$$

Step 5: For values of A falling to the left of the applicable material/temperature line for the Design Temperature, the value of P_a can be calculated using the following equation:

$$P_a = \frac{0.0625E}{(R_o/T)^2}$$

Step 6: Compare P_a obtained in Steps 4 or 5 with P . If P_a is smaller than P , select a larger value for T and repeat the design procedure until a value for P_a is obtained that is equal to or greater than P .

(b) *Hemispherical Heads*. The required thickness of a hemispherical head having pressure on the convex side shall be determined in the same manner as outlined in (a) above for determining the thickness for a spherical shell.

(c) *Ellipsoidal Heads*. The required thickness of an ellipsoidal head having pressure on the convex side, either seamless or of built-up construction with butt joints, shall not be less than that determined by the following procedure.

Step 1: Assume a value for T and calculate the value of factor A using the following equation:

Page 59

$$A = \frac{0.125}{(R_o/T)}$$

Step 2: Using the value of A calculated in Step 1, follow the same procedure as that given for spherical shells in (a) above, Steps 2 through 6.

(d) *Torispherical Heads*. The required thickness of a torispherical head having pressure on the convex side, either seamless or of built-up construction with butt joints, shall not be less than that determined by the same design procedure as is used for ellipsoidal heads given in (d) above, using the appropriate value for R_o .

(e) *Conical Heads and Sections*. The required thickness of a conical head or section under pressure on the convex side, either seamless or of built-up construction with butt joints, shall be determined in accordance with the following subparagraphs.

(1) When α is equal to or less than 60 deg

(a) Cones having D_L/T_e values ≥ 10 :

Step 1: Assume a value for T_e and determine the ratios L/D_L and D_L/T_e .

Step 2: Enter Fig. G, Section II, Part D, Subpart 3 at a value of L/D_o equivalent to the value of L/D_L determined in Step 1. For values of L/D_L greater than 50, enter the chart at a value of $L/D_L = 50$.

Step 3: Move horizontally to the line for the value of D_o/T equivalent to the value of D_L/T_e determined in Step 1. Interpolation may be made for intermediate values of D_L/T_e . From this point of intersection move vertically downward to determine the value of factor A .

Step 4: Using the value of A calculated in Step 3, enter the applicable material chart in Section II, Part D, Subpart 3 for the material under consideration. Move vertically to an intersection with the material/temperature line for the design temperature (see ND-3112.2). Interpolation may be made between lines for intermediate temperatures. In cases where the value of A falls to the right of the end of the material/temperature line, assume an intersection with the horizontal projection of the upper end of the material/temperature line. For values of A falling to the left of the material/temperature line, see Step 7.

Step 5: From the intersection obtained in Step 4, move horizontally to the right and read the value of factor B .

Step 6: Using this value of B , calculate the value of the maximum allowable external pressure P_a using the following formula:

$$P_a = \frac{4B}{3(D_L / T_e)}$$

Step 7: For values of A falling to the left of the applicable material/temperature line, the value of P_a can be calculated using the following formula:

$$P_a = \frac{2AE}{3(D_L / T_e)}$$

Step 8: Compare the calculated value of P_a obtained in Steps 6 or 7 with P . If P_a is smaller than P , select a larger value for T and repeat the design procedure until a value of P_a is obtained that is equal to or greater than P .

Step 9: Provide adequate reinforcement of the cone-to-cylinder juncture according to Appendix XXII.

(b) Cones having D_L/T_e values < 10:

Step 1: Using the same procedure as given in (e)(1)(a) above, obtain the value of B . For values of D_L/T_e less than 4, the value of factor A can be calculated using the following formula:

$$A = \frac{1.1}{(D_L / T_e)^2}$$

For values of A greater than 0.10, use a value of 0.10.

Step 2: Using the value of B obtained in Step 1, calculate a value P_{a1} using the following formula:

$$P_{a1} = \left[\frac{2.167}{(D_L/T_e)} - 0.0833 \right] B$$

Step 3: Calculate a value P_{a1} using the following formula:

$$P_{a2} = \frac{2S'}{D_L/T_e} - \frac{1}{D_L/T_e}$$

Step 4: The smaller of the values of P_{a1} calculated in Step 2, or P_{a2} calculated in Step 3 shall be used for the maximum allowable external pressure P_a . Compare P_a with P . If P_a is

Page 60

smaller than P , select a larger value for T and repeat the design procedure until a value for P_a is obtained that is equal to or greater than P .

Step 5: Provide adequate reinforcement of the cone-to-cylinder juncture according to Appendix XXII.

(2) When α of the cone is greater than 60 deg, the thickness of the cone shall be the same as the required thickness for a flat head under external pressure, the diameter of which equals the largest diameter of the cone (see ND-3325).

(3) The thickness of an eccentric cone shall be taken as the greater of the two thicknesses obtained using both the smallest and largest α in the calculations.

(f) The required thickness of a toriconical head having pressure on the convex side, either seamless or of built-up construction with butt joints within the head, shall not be less than that determined from (e) above with the exception that L_e shall be determined as follows.

(1) For sketch (c) in Fig. ND-3133.4-1:

$$L_e = r_1 \sin \theta_1 + \frac{L}{2} \left(\frac{D_L + D_s}{D_{Ls}} \right)$$

(2) For sketch (d) in Fig. ND-3133.4-1:

$$L_e = r_2 \frac{D_{ss}}{D_L} \sin \theta_2 + \frac{L}{2} \left(\frac{D_L + D_s}{D_L} \right)$$

(3) For sketch (e) in Fig. ND-3133.4-1:

$$L_e = r_1 \sin \theta_1 + r_2 \frac{D_{ss}}{D_{Ls}} \sin \theta_2 + \frac{L}{2} \frac{(D_L + D_s)}{D_{Ls}}$$

(g) When lap joints are used in formed head construction or for longitudinal joints in a conical head under external pressure, the thickness shall be determined by the rules in this paragraph, except that $2P$ shall be used instead of P in the calculations for the required thickness.

(h) The required length of skirt on heads convex to pressure shall comply with the provisions of ND-3324.5(c) and (i) for heads concave to pressure.

(i) Openings in heads convex to pressure shall comply with the requirements of ND-3330.

(j) When necessary, provisions shall be made to vessels and heads to prevent overstressing and excessive distortion due to external loads other than pressure and temperature (see ND-3111).

ND-3133.5 Stiffening Rings for Cylindrical Shells

(a) The required moment of inertia of a circumferential stiffening ring shall be not less than that determined by one of the following two equations:

$$I_s = \frac{D_o^2 L_s (T + A_s / L_s) A}{14}$$

$$I_s' = \frac{D_o^2 L_s (T + A_s / L_s) A}{10.9}$$

If the stiffeners should be so located that the maximum permissible effective shell sections overlap on either or both sides of a stiffener, the effective shell section for that stiffener shall be shortened by one-half of each overlap. Stiffening rings shall be designed to preclude lateral buckling.

(b) The available moment of inertia I or I' for a stiffening ring shall be determined by the following procedure.

Step 1: Assuming that the shell has been designed and D_o , L_s , and T_n are known, select a member to be used for the stiffening ring and determine its cross-sectional area A_s . Then calculate factor B , psi, using the following equation:

$$B = 3/4 \left(\frac{PD_o}{T_n + A_s/L_s} \right)$$

Step 2: Enter the right-hand side of the applicable material chart in Section II, Part D, Subpart 3 for the material under consideration at the value of B determined by Step 1. If different materials are used for the shell and stiffening ring, use the material chart resulting in the larger value of A in Step 4 or 5 below.

Step 3: Move horizontally to the left to the material/temperature line for the design metal temperature. For values of B falling below the left end of the material/temperature line, see Step 5.

Step 4: Move vertically to the bottom of the chart and read the value of A .

Step 5: For values of B falling below the left end of the material/temperature line for the Design Temperature, the value of A can be calculated using the equation:

FIG. ND-3133.4-1 LENGTH L OF SOME TYPICAL CONICAL SECTIONS

FIG. ND-3133.4-1 LENGTH L OF SOME CONICAL SECTIONS

$$A = 2B/E$$

Step 6: Compute the value of the required moment of inertia from the equations for I_s or I'_s above.

Step 6

Step 7: Calculate the available moment of inertia I or I' of the stiffening ring using the section corresponding to that used

in Step 6.

Step 8: If the required moment of inertia is greater than the moment of inertia for the section selected in Step 1, a new section with a larger moment of inertia must be selected and a new moment of inertia determined. If the required moment of inertia is smaller than the moment of inertia for the section selected in Step 1, that section should be satisfactory.

(c) For fabrication and installation requirements for stiffening rings, see ND-4430.

ND-3133.6 Cylinders Under Axial Compression.

The maximum allowable compressive area to be used in the design of cylindrical shells and tubular products subjected to loadings that produce longitudinal compressive stresses in the shell or wall shall be the lesser of the values given in (a) and (b) below:

Page 62

(a) the S value for the applicable material at Design Temperature given in Tables 1A and 1B, Section II, Part D, Subpart 1;

(b) the value of the factor B determined from the applicable chart in Section II, Part D, Subpart 3. The value of B shall be determined from the applicable chart contained in Section II, Part D, Subpart 3 as given in Steps 1 through 5.

Step 1: Using the selected values of T and R , calculate the value of factor A using the following equation:

$$A = \frac{0.125}{(R/T)}$$

Step 2: Using the value of A calculated in Step 1, enter the applicable material chart in Section II, Part D, Subpart 3 for the material under consideration. Move vertically to an intersection with the material/temperature line for the Design Temperature. Interpolation may be made between lines for intermediate temperatures. In cases where the value at A falls to the right of the end of the material/temperature line, assume an intersection with the horizontal projection of the upper end of the material/temperature line. For values of A falling to the left of the material/temperature line, see Step 4.

Step 3: From the intersection obtained in Step 2, move horizontally to the right and read the value of factor B . This is the maximum allowable compressive stress for the values of T and R used in Step 1.

Step 4: For values of A falling to the left of the applicable material/temperature line, the value of B shall be calculated using the following equation:

$$B = \frac{AE}{2}$$

Step 5: Compare the value of B determined in Steps 3 or 4 with the computed longitudinal compressive stress in the cylindrical shell or tube, using the selected values of T and R . If the value of B is smaller than the computed compressive stress, a greater value of T must be selected and the design procedure repeated until a value of B is obtained which is greater than the compressive stress computed for the loading on the cylindrical shell or tube. The joint efficiency for butt welded joints may be taken as unity.

ND-3133.7 Tubes and Pipes When Used as Tubes.

The required wall thickness for tubes and pipe under external pressure shall be determined in accordance with Fig. ND-3133.7-1.

ND-3135 Attachments

(a) Except as in (c) and (d) below, attachments and connecting welds within the jurisdictional boundary of the component as defined in ND-1130 shall meet the stress limits of the component.

(b) The design of the component shall include consideration of the interaction effects and loads transmitted through the attachment to and from the pressure retaining portion of the component.

(c) Beyond $2t$ from the pressure retaining portion of the component, where t is the nominal thickness of the pressure retaining material, the appropriate design rules of NF-3000 may be used as a substitute for the design rules of ND-3000 for portions of attachments which are in the component support load path.

(d) Nonstructural attachments shall meet the requirements of ND-4435.

ND-3300 VESSEL DESIGN

ND-3310 GENERAL REQUIREMENTS

Class 3 vessel requirements as stipulated in the Design Specifications (NCA-3250) shall conform to the design requirements of this Article.

ND-3320 DESIGN CONSIDERATIONS

ND-3321 Stress Limits for Design and Service Loadings

Stress² limits for Design and Service Loadings are specified in Table ND-3321-1. The symbols used in Table ND-3321-1

are defined as follows:

σ_m

= general membrane stress, psi. This stress is equal to the average stress across the solid section under consideration. It excludes discontinuities and concentrations, and is produced only by pressure and other mechanical loads.

σ_L

= local membrane stress, psi. This stress is the same as σ_m , except that it includes the effect of discontinuities.

2 Stress means the maximum normal stress

Page 63

Page 64

FIG. ND-3133.7-1 CHART FOR DETERMINING WALL THICKNESS OF TUBES UNDER EXTERNAL PRESSURE

FIG. ND-3133.7-1 CHART FOR DETERMINING WALL THICKNESS OF TUBES UNDER EXTERNAL PRESSURE

σ_b	= bending stress, psi. This stress is equal to the linear varying portion of the stress across the solid section under consideration. It excludes discontinuities and concentrations, and is produced only by pressure and other mechanical loads.
S	= allowable stress value given in Tables 1A and 1B, Section II, Part D, Subpart 1, psi. The allowable stress shall correspond to the highest metal temperature at the section under consideration during the condition under consideration.

**TABLE ND-3321-1
STRESS LIMITS FOR DESIGN AND
SERVICE LOADINGS¹**

p

Service Limit	Stress Limits [Note (2)]
Design and Level A	$\sigma_m \leq 1.0S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.5S$
Level B	$\sigma_m \leq 1.10S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.65S$
Level C	$\sigma_m \leq 1.5S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.8S$
Level D	$\sigma_m \leq 2.0S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 2.4S$

NOTES:

(1) See ND-3321.1 for definitions of symbols.

(2) These limits do not take into account either local or general buckling which might occur in thin wall vessels.

TABLE ND-3321-1 STRESS LIMITS FOR DESIGN AND SERVICE LOADINGS¹

Typical examples of locations for which σ_m , σ_L , and σ_b are applicable are shown in Table ND-3321-2.

ND-3322 Special Considerations

The provisions of ND-3120 apply.

ND-3323 General Design Rules

The provisions of ND-3130 apply except as modified by the rules of this Subarticle. In case of conflict, this Subarticle governs the design of vessels.

ND-3324 Components Under Internal Pressure

ND-3324.1 General Requirements.

Equations are given for determining the minimum thicknesses under internal pressure loading in cylindrical and spherical shells and ellipsoidal, torispherical, conical, toriconical, and hemispherical heads. Provision shall be made for any of the other loadings listed in ND-3111 when such loadings are specified.

[98]

ND-3324.2 Nomenclature.

The symbols used in this paragraph and Fig. ND-3324.2-1 are defined as follows:

t	= minimum required thickness of shell or head after forming, exclusive of corrosion allowance, in.
P	= Design Pressure, psi
R	= inside radius of the shell course under consideration before corrosion allowance is added, in.
R_o	= outside radius of the shell course under consideration, in.
S	= maximum allowable stress value, psi (Tables 1A and 1B, Section II, Part D, Subpart 1)
D	= inside diameter of the head skirt; or inside length of the major axis of an ellipsoidal head; or inside diameter of a conical head at the point under consideration, measured perpendicular to the longitudinal axis, in.
D_o	= outside diameter of the head skirt; or outside length of the major axis of an ellipsoidal head; or outside diameter of a conical head at the point under consideration, measured perpendicular to the longitudinal axis, in.
D_1	= inside diameter of the conical portion of a toriconical head at its point of tangency to the knuckle, measured perpendicular to the axis of the cone, in.
L	= inside spherical or crown radius for torispherical and hemispherical heads, in.
L	= $K_1 D$ for ellipsoidal heads in which K_1 is obtained from Table ND-3332.2-1
L_o	= outside spherical or crown radius, in.
r	= inside knuckle radius, in.
h	= one-half of the length of the minor axis of the ellipsoidal head or the inside depth of the ellipsoidal head measured from the tangent line (head-bend line), in.

K

= a factor in the equations for ellipsoidal heads depending on the head proportion $D/2h$ (Table ND-3324.2-1)

$D/2h$

= ratio of the major to the minor axis of ellipsoidal heads, which equals the inside diameter of the skirt of the head divided by twice the inside height of the head and is used in Table ND-3324.2-1

α

= one-half of the included apex angle of the cone at the center line of the head

E

= joint efficiency for, or the efficiency of, appropriate joint in the shell or head; for hemispherical heads this includes head-to-shell joints. For welded construction use the value of E specified in ND-3352. For seamless heads use $E = 1$, except for hemispherical heads furnished without a skirt, in which case the head-to-shell joint must be considered.

[98]

Pages 66-66

TABLE ND-3321-2
CLASSIFICATION OF STRESS IN VESSELS FOR SOME TYPICAL CASES¹

Vessel Part	Location	Origin of Stress	Type of Stress	Classification
Cylindrical or spherical shell	Shell plate remote from discontinuities	Internal pressure	General membrane Gradient through plate thickness	σ_m Q
		Axial thermal gradient	Membrane Bending	Q Q
	Junction with head or flange	Internal pressure	Membrane Bending	σ_L Q [Note (2)]
Any shell or head	Any section across entire vessel	External load or moment, or internal pressure	General membrane averaged across full section. Stress component perpendicular to cross section.	σ_m
		External load or moment	Bending across full section. Stress component perpendicular to cross section.	σ_m
	Near nozzle or other opening	External load or moment, or internal pressure	Local membrane Bending Peak (fillet or corner)	σ_L Q F
	Any location	Temperature difference between shell and head	Membrane Bending	Q Q
Dished head or conical head	Crown	Internal pressure	Membrane Bending	σ_m σ_b
	Knuckle or junction to shell	Internal pressure	Membrane Bending	σ_L [Note (3)] Q
Flat head	Center region	Internal pressure	Membrane Bending	σ_m σ_b
	Junction to shell	Internal pressure	Membrane Bending	σ_L [Note (2)] Q
Perforated head or shell	Typical ligament in a uniform pattern	Pressure	Membrane (averaged through cross section) Bending (averaged through width of ligament, but gradient through plate) Peak	σ_m σ_b F
	Isolated or atypical ligament		Membrane Bending Peak	Q F F

TABLE ND-3321-2 (CONT'D)
CLASSIFICATION OF STRESS IN VESSELS FOR SOME TYPICAL CASES¹

Vessel Part	Location	Origin of Stress	Type of Stress	Classification
Nozzle	Within the limits of reinforcement defined by ND-3334	Pressure and external loads and moments, including those attributable to restrained free end displacements of attached piping	General membrane	σ_m
			Bending (other than gross structural discontinuity stresses) averaged through nozzle thickness	σ_m
	Outside the limits of reinforcement defined by ND-3334	Pressure and external axial, shear, and torsional loads other than those attributable to restrained free end displacements of attached piping	General membrane stresses	σ_m
		Pressure and external loads and moments other than those attributable to restrained free end displacements of the attached piping	Membrane	σ_L
			Bending	σ_b
	Nozzle wall	Pressure and all external loads and moments	Membrane	σ_L
			Bending	Q
			Peak	F
Cladding	Any	Differential expansion	Local membrane	σ_L
			Bending	Q
Any	Any	Radial temp. distribution [Note (4)]	Peak	F
			Membrane	Q
			Bending	F
Any	Any	Any	Nonlinear portion of stress distribution	F
			Stress concentration (notch effect)	F

NOTES:

- (1) Q and F classifications of stresses refer to other than Design Condition.
- (2) If the bending moment at the edge is required to maintain the bending stress in the middle within acceptable limits, the edge bending is classified as σ_b . Otherwise, it is classified as Q .
- (3) Consideration must also be given to the possibility of wrinkling and excessive deformation in vessels with a large diameter-thickness ratio.
- (4) Consider possibility of thermal stress ratchet.
- (5) Equivalent linear stress is defined as the linear distribution which has the same net bending moment as the actual stress distribution.

TABLE ND-3321-2 (CONT'D) CLASSIFICATION OF STRESS IN VESSELS FOR SOME TYPICAL CASES¹

FIG. ND-3324.2-1 PRINCIPAL DIMENSIONS OF TYPICAL HEADS

TABLE ND-3324.2-1 VALUES OF FACTOR K

ND-3324.3 Cylindrical Shells.

The minimum thickness of cylindrical shells shall be the greater thickness as given by (a) through (d) below.

(a) *Circumferential Stress (Longitudinal Joints).* When the thickness does not exceed one-half of the inside radius, or P does not exceed $0.385SE$, the following equations shall apply:

$$t = \frac{PR}{SE - 0.6P} \quad \text{or} \quad P = \frac{SEt}{R + 0.6t}$$

(b) *Longitudinal Stress (Circumferential Joints)*. When the thickness does not exceed one-half of the inside radius, or P does not exceed $1.25SE$, the following equations shall apply:

Page 68

$$t = \frac{PR}{2SE + 0.4P} \quad \text{or} \quad P = \frac{2SEt}{R - 0.4t}$$

(c) *Thickness of Cylindrical Shells*. The following equations, in terms of the outside radius, are equivalent to and may be used instead of those given in (a) above:

$$t = \frac{PR_o}{SE + 0.4P} \quad \text{or} \quad P = \frac{SEt}{R_o - 0.4t}$$

(d) *Thick Cylindrical Shells*

(1) *Circumferential Stress (Longitudinal Joints)*. When the thickness of the cylindrical shell under internal pressure exceeds one-half of the inside radius or when P exceeds $0.385SE$, the following equations shall apply. When P is known and t is desired:

$$t = R (Z^{1/2} - 1) = R_o \frac{Z^{1/2} - 1}{Z^{1/2}}$$

where

$$Z = \frac{SE + P}{SE - P}$$

When t is known and P is desired:

$$P = SE \left(\frac{Z - 1}{Z + 1} \right)$$

where

$$Z = \left(\frac{R + t}{R} \right)^2 = \left(\frac{R_o}{R} \right)^2 = \left(\frac{R_o}{R_o - t} \right)^2$$

(2) *Longitudinal Stress (Circumferential Joints)*. When the thickness of the cylindrical shell under internal pressure exceeds one-half of the inside radius or when P exceeds $1.25SE$, the following equations shall apply. When P is known and t is desired:

$$t = R(Z^{1/2} - 1) = R_o \left(\frac{Z^{1/2} - 1}{Z^{1/2}} \right)$$

where

where

$$Z = \frac{P}{SE} + 1$$

When t is known and P is desired:

$$P = SE(Z - 1)$$

where

$$Z = \left(\frac{R + t}{R} \right)^2 = \left(\frac{R_o}{R} \right)^2 = \left(\frac{R_o}{R_o - t} \right)^2$$

ND-3324.4 Spherical Shells

(a) When the thickness of the shell of a spherical vessel does not exceed $0.356R$ or P does not exceed $0.665S$, the following equations shall apply. Any reduction in thickness within a shell course of a spherical shell shall be in accordance with ND-3361.

$$t = \frac{PR}{2SE - 0.2P} \quad \text{or} \quad P = \frac{2SEt}{R + 0.2t}$$

(b) The following equations, in terms of the outside radius, are equivalent and may be used instead of those given in (a) above:

$$t = \frac{PR_o}{2SE + 0.8P}$$

$$P = \frac{2SEt}{R_o - 0.8t}$$

(c) When the thickness of the shell of a spherical vessel under internal pressure exceeds $0.356R$ or when P exceeds $0.665SE$, the following equations shall apply. When P is known and t is desired:

$$t = R (Y^{1/3} - 1) = R_o \left(\frac{Y^{1/3} - 1}{Y^{1/3}} \right)$$

where

$$Y = \frac{2(SE + P)}{2SE - P}$$

When t is known and P is desired:

$$P = 2SE \left(\frac{Y - 1}{Y + 2} \right)$$

where

$$Y = \left(\frac{R + t}{R} \right)^3 = \left(\frac{R_o}{R_o - t} \right)^3$$

ND-3324.5 Formed Heads, General Requirements.

Formed heads shall meet the requirements of (a) through (i) below.

(a) All formed heads, thicker than the shell and concave to pressure, for butt welded attachment, shall have a skirt length sufficient to meet the requirements of Fig. ND-3358.1(a)-1 when a tapered transition is required.

(b) Any taper at a welded joint within a formed head shall be in accordance with ND-3361. The taper at a circumferential welded joint connecting a formed head to a main shell shall meet the requirements of ND-3358 for the respective type of joint shown therein.

(c) All formed heads concave to pressure and for butt welded attachment need not have an integral skirt when the thickness of the head is equal to or less than the thickness of the shell. When a skirt is provided, its thickness shall be at least that required for a seamless shell of the same diameter.

(d) The inside crown radius to which an unstayed head is dished shall be not greater than the outside diameter of the skirt of the head. The inside knuckle radius of a torispherical head shall be not less than 6% of the outside diameter of the skirt of the head but in no case less than three times the head thickness.

(e) When an ellipsoidal, torispherical, hemispherical, conical, or toriconical head is of a lesser thickness than required by the rules of ND-3324.5, it shall be stayed as a flat surface according to the rules of ND-3329.

(f) If a torispherical, ellipsoidal, or hemispherical head is formed with a flattened spot or surface, the diameter of the flat spot shall not exceed that permitted for flat heads as given by Eq. (4) or (5) of ND-3325.2 using $C = 0.25$.

(g) Openings in formed heads under internal pressure shall comply with the requirements of ND-3330.

(h) A dished head with a reversed skirt may be used in a component, provided the maximum allowable pressure for the head is established in accordance with the requirements of ND-6900.

(i) Heads concave to pressure, intended for attachment by brazing, shall have a skirt length sufficient to meet the requirements for circumferential joints (ND-4500).

ND-3324.6 Ellipsoidal Heads

(a) *2:1 Ellipsoidal Heads*. The required thickness of a dished head of semiellipsoidal form, in which one-half the minor axis (inside depth of the head minus the skirt) equals one-fourth the inside diameter of the head skirt, shall be determined by:

$$t = \frac{PD}{2SE - 0.2P} \quad \text{or} \quad P = \frac{2SEt}{D + 0.2t}$$

(b) *Ellipsoidal Heads of Other Ratios*. The minimum required thickness of an ellipsoidal head of other than a 2:1 ratio shall be determined by:

$$t = \frac{PDK}{2SE - 0.2P} \quad \text{or} \quad P = \frac{2SEt}{KD + 0.2t}$$

$$t = \frac{PD_o K}{2SE + 2P(K - 0.1)}$$

or

$$P = \frac{2SEt}{KD_o - 2t(K - 0.1)}$$

where

$$K = \frac{1}{6} \left[2 + \left(\frac{D}{2h} \right)^2 \right]$$

Numerical values of the factor K are given in Table ND-3324.2-1.

ND-3324.7 Hemispherical Heads

(a) When the thickness of a hemispherical head does not exceed $0.356L$ or P does not exceed $0.665SE$, the following equations shall apply:

$$t = \frac{PL}{2SE - 0.2P} \quad \text{or} \quad P = \frac{2SEt}{L + 0.2t}$$

(b) When the thickness of the hemispherical head under internal pressure exceeds $0.356L$ or when P exceeds $0.665SE$, the following equations shall apply:

$$t = L(Y^{1/3} - 1) = L_o \left(\frac{Y^{1/3} - 1}{Y^{1/3}} \right)$$

where

$$Y = \frac{2(SE + P)}{2SE - P}$$

or

$$P = 2S \left(\frac{Y - 1}{Y + 2} \right)$$

where

$$Y = \left(\frac{L + t}{L} \right)^3 = \left(\frac{L_o}{L_o - t} \right)^3$$

ND-3324.8 Torispherical Heads

(a) *Torispherical Heads With 6% Knuckle Radius.* The required thickness of a torispherical head in which the knuckle radius is 6% of the inside crown radius shall be determined by:

$$t = \frac{0.885PL}{SE - 0.1P} \quad \text{or} \quad P = \frac{SEt}{0.885L + 0.1t}$$

(b) *Torispherical Heads of Other Proportions.* The required thickness of a torispherical head in which the knuckle radius is other than 6% of the crown radius shall be determined by:

$$t = \frac{PLM}{2SE - 0.2P} \quad \text{or} \quad P = \frac{2SEt}{LM + 0.2t}$$

$$t = \frac{PL_oM}{2SE + P(M - 0.2)} \quad (1)$$

(1)

or

$$P = \frac{2SEt}{ML_o - t(M - 0.2)} \quad (2)$$

(2)

where

$$M = \frac{1}{4} \left(3 + \sqrt{\frac{L}{r}} \right) \quad (3)$$

(3)

Numerical values of the factor M are given in Table ND-3324.8(b)-1.

(c) Torispherical heads made of material having a specified minimum tensile strength exceeding 80.0 ksi (552 MPa) shall be designed using a value of S equal to 20.0 ksi (138 MPa) at room temperature and reduced in proportion to the reduction in maximum allowable stress values at temperature for the material as shown in Tables 1A and 1B, Section II, Part D, Subpart 1.

ND-3324.9 Conical Heads Without Transition Knuckle.

The required thickness of conical heads or conical shell sections that have a half-apex angle α not greater than 30 deg shall be determined by:

$$t = \frac{PD}{2 \cos \alpha (SE - 0.6P)} \quad \text{or} \quad P = \frac{2SEt \cos \alpha}{D + 1.2t \cos \alpha}$$

For α greater than 30 deg, see ND-3324.11(b)(5). A compression ring shall be provided when required by the rule in ND-3324.11(b).

ND-3324.10 Toriconical Heads.

Toriconical heads in which the inside knuckle radius is neither less than 6% of the outside diameter of the head skirt nor less than three times the knuckle thickness shall be used when the angle α exceeds 30 deg except when the design complies with ND-3324.11. The required thickness of the knuckle shall be determined by the first equation of ND-3324.8(b) in which:

$$L = \frac{D_1}{2 \cos \alpha}$$

The required thickness of the conical portion shall be determined by the equation in ND-3324.9, using D_1 in place of D .

ND-3324.11 Reducer Sections

(a) General Requirements

(1) The rules of ND-3324.11(a) apply to concentric reducer sections.

(2) The symbols used are defined as follows:

D_1	= inside diameter of reducer section at point of tangency to the knuckle or reverse curve, in.
A	= required area of reinforcement, sq in.
A_e	= effective area of reinforcement, due to excess metal thickness, sq in.
Δ	= value to indicate need for reinforcement at cone-to-cylinder intersection having a half-apex angle $\alpha \leq 30$ deg. When $\Delta \geq \alpha$, no reinforcement at the junction is required [Tables ND-3324.11(b)(2)-1 and ND-3324.11(b)(3)-1]
m	= the lesser of $(t_s/t) \cos (\alpha - \Delta)$ or

$$\frac{[t_c \cos \alpha \cos (\alpha - \Delta)]}{t}$$

R_L	= inside radius of larger cylinder, in.
R_s	= inside radius of smaller cylinder, in.
r_L	= inside radius of knuckle at larger cylinder, in.

r_s

= radius to the inside surface of flare at the small end, in.

 t_s

= nominal thickness of cylinder at cone-to-cylinder junction, exclusive of corrosion allowance, in.

Page 71

 t_c

= nominal thickness of cone at cone-to-cylinder junction, exclusive of corrosion allowance, in.

 t_e = the smaller of $(t_s - t)$ or $[t_c - (t/\cos \alpha)]$, in.

TABLE ND-3324.8(b)-1
VALUES OF FACTOR M
 Use Nearest Value of L/r ; Interpolation Unnecessary

L/r	1.0	1.25	1.50	1.75	2.00	2.25	2.50	2.75	3.00	3.25	3.50
M	1.00	1.03	1.06	1.08	1.10	1.13	1.15	1.17	1.18	1.20	1.22
L/r	4.0	4.5	5.0	5.5	6.0	6.5	7.0	7.5	8.0	8.5	9.0
M	1.25	1.28	1.31	1.34	1.36	1.39	1.41	1.44	1.46	1.48	1.50
L/r	9.5	10.00	10.5	11.0	11.5	12.0	13.0	14.0	15.0	16.0	16.67 [Note (1)]
M	1.52	1.54	1.56	1.58	1.60	1.62	1.65	1.69	1.72	1.75	1.77

NOTE:(1) Maximum ratio allowed by ND-3324.5(d) when L equals the outside diameter of the skirt of the head.

TABLE ND-3324.8(b)-1 VALUES FOR FACTOR M

(3) The thickness of each element of a reducer, as defined in (4) below, under internal pressure shall not be less than that computed by the applicable equation. In addition, provisions shall be made for any of the other loadings listed in ND-3111 when such loadings are expected.

(4) A transition section reducer consisting of one or more elements may be used to join two cylindrical shell sections of different diameters but with a common axis, provided the requirements of (a) and (b) below are met.

(a) *Conical Shell Section.* The required thickness of a conical shell section or the allowable pressure for such a section of given thickness shall be determined by the equations given in ND-3324.9.

(b) *Knuckle Tangent to the Larger Cylinder.* Where a knuckle is used at the large end of a reducer section, its shape shall be that of a portion of an ellipsoidal, hemispherical, or torispherical head. The thickness and other dimensions shall satisfy the requirements of ND-3324.

(5) When elements of (4) above having different thicknesses are combined to form a reducer, the joints, including the plate taper required by ND-3361, shall lie entirely within the limits of the thinner element being joined.

(6) A reducer may be a simple conical shell section [Fig. ND-3324.11(a)(6)-1 sketch (a)] without knuckle provided the half apex angle α is not greater than 30 deg, except as provided for in (b) below. A reinforcement ring shall be provided at either or both ends of the reducer when required by (b) below.

(7) A toriconical reducer [Fig. ND-3324.11(a)(6)-1 sketch (b)] may be shaped as a portion of a toriconical shell, a portion of a hemispherical head plus a conical section, or a portion of an ellipsoidal head plus a conical section provided the half apex angle α is not greater than 30 deg, except as provided for in (b) below. A reinforcement ring shall be provided at the small end of a conical reducer element when required by (b) below.

(8) Reverse curve reducers [Fig. ND-3324.11(a)(6)-1 sketches (c) and (d)] may be shaped of elements other than those as illustrated.

(b) Supplementary Requirements for Reducer Sections and Conical Heads Under Internal Pressure

(1) The equations of (2) and (3) below provide for the design of reinforcement, if needed, at the cone-to-cylinder junctions for reducer sections and conical heads where all the elements have a common axis and the half apex angle $\alpha \leq 30$ deg. In (5) below, provision is made for special analysis in the design of cone-to-cylinder intersections with or without reinforcing rings where α is greater than 30 deg.

(2) Reinforcement shall be provided at the junction of the cone with the large cylinder for conical heads and reducers without knuckles when the value of Δ , obtained from Table ND-3324.11(b)(2)-1, using the appropriate ratio P/SE , is less than α . Interpolation may be made in the Table.

(a) The cross-sectional area of the reinforcement ring shall be at least equal to that indicated by the following equation:

$$A = \frac{P(R_L)^2}{2SE} \left(1 - \frac{\Delta}{\alpha} \right) \tan \alpha$$

(b) When the thickness, less corrosion allowance, of both the reducer and cylinder exceeds that

GENERAL NOTES:

- (1) r_L shall not be less than the smaller of $0.12 (R_L + t)$ or $3t$
- (2) r_s has no dimensional requirement

FIG. ND-3324.11(a)(6)-1 LARGE HEAD OPENINGS, REVERSE CURVE, AND CONICAL SHELL REDUCER SECTIONS

FIG. ND-3324.11(a)(6)-1 LARGE HEAD OPENINGS, REVERSE CURVE, AND CONICAL SHELL REDUCER SECTIONS

required by the applicable design equations, the minimum excess thickness may be considered to contribute to the required reinforcement ring in accordance with the following equation:

**TABLE ND-3324.11(b)(2)-1
VALUES OF Δ FOR JUNCTIONS AT THE
LARGE CYLINDER FOR $\alpha \leq 30$ deg**

<i>P/SE</i>	0.001	0.002	0.003	0.004	0.005
Δ, deg	11	15	18	21	23
<i>P/SE</i>	0.006	0.007	0.008	0.009 [Note (1)]	...
Δ, deg	25	27	28.5	30	...

NOTE:

(1) $\Delta = 30$ deg for greater values of P/SE .

TABLE ND-3324.11(b)(2)-1 VALUES OF Δ FOR JUNCTIONS AT THE LARGE CYLINDER FOR $\alpha \leq 30$ deg

$$A_e = 4t_e \sqrt{R_{Ls} t_s}$$

(c) Any additional area of reinforcement which is required shall be situated within a distance of $\sqrt{R_{Ls} t_s}$ from the junction of the reducer and the cylinder. The centroid of the added area shall be within a distance of $0.5\sqrt{R_{Ls} t_s}$ from the junction.

(3) Reinforcement shall be provided at the junction of the conical shell of a reducer without a flare and the small cylinder when the value of Δ obtained from

**TABLE ND-3324.11(b)(3)-1
VALUES OF Δ FOR JUNCTIONS AT THE
SMALL CYLINDER FOR $\alpha \leq 30$ deg**

P/SE	0.002	0.005	0.010	0.02
Δ, deg	4	6	9	12.5
P/SE	0.04	0.08	0.10	0.125 [Note (1)]
Δ, deg	17.5	24	27	30

NOTE:

(1) $\Delta = 30$ deg for greater values of P/SE .

TABLE ND-3324.11(b)(3)-1 VALUES OF Δ FOR JUNCTIONS AT THE SMALL CYLINDER FOR $\alpha \leq 30$ deg

Table ND-3324.11(b)(3)-1, using the appropriate ratio P/SE , is less than α .

(a) The cross-sectional area of the reinforcement ring shall be at least equal to that indicated by the following equation:

$$A = \frac{PR_s^2}{2SE} \left(1 - \frac{\Delta}{\alpha} \right) \tan \alpha$$

(b) When the thickness, less corrosion allowance, of either the reducer or cylinder exceeds that required by the applicable design equation, the excess thickness may be considered to contribute to the required reinforcement ring in

$$A_e = m \sqrt{R_s t} [t_c - (t / \cos \alpha) + (t_s - t)]$$

(c) Any additional area of reinforcement which is required shall be situated within a distance of $\sqrt{R_s t_s}$ from the junction, and the centroid of the added area shall be within a distance of $0.5\sqrt{R_s t_s}$ from the junction.

(4) Reducers not described in ND-3324.11(a)(3), such as those made up of two or more conical frustums having different slopes, may be designed in accordance with (5) below.

(5) When the half apex angle α is greater than 30 deg, cone-to-cylinder junctions without a knuckle may be used, with or without reinforcing rings, if the design is based on stress analysis. When such an analysis is made, the calculated localized stresses at the discontinuity shall not exceed the following values.

(a) Membrane hoop stress plus average discontinuity hoop stress shall not be greater than $1.5 SE$.

(b) Membrane longitudinal stress plus discontinuity longitudinal stress due to bending shall not be greater than $4SE$, where the average discontinuity hoop stress is the average hoop stress across the wall thickness due to the discontinuity at the junction, disregarding the effect of Poisson's ratio times the longitudinal stress at the surfaces.

(c) The angle joint between the cone and cylinder shall be designed equivalent to a double butt welded joint, and, because of the high bending stress, there shall be no weak zones around the angle joint. The thickness of the cylinder may have to be increased to limit the difference in thickness so that the angle joint has a smooth contour.

ND-3324.12 Nozzles

(a) The wall thickness of a nozzle or other connection shall not be less than the nominal thickness of the connecting piping. In addition, the wall thickness shall not be less than the thickness computed for the applicable loadings in ND-3111 plus the thickness added for corrosion allowance. Except for access openings and openings for inspection only, the wall thickness shall not be less than the smaller of (1) and (2) below:

(1) the required thickness of the shell or head to which the connection is attached plus the corrosion allowance provided in the shell or head adjacent to the connection;

³ The minimum thickness for all pipe materials is the nominal wall thickness listed in Table 2 of ANSI B36.10 less $12\frac{1}{2}\%$. For diameters other than those listed in the table, this shall be based on the next larger pipe size.

(2) the minimum thickness³ of standard wall pipe plus the corrosion allowance on the connection; for nozzles larger than the largest pipe size included in ANSI B36.10, the wall thickness of that largest size plus corrosion allowance.

(b) The allowable stress value for shear in a nozzle neck shall be 70% of the allowable tensile stress for the vessel material.

ND-3324.13 Nozzle Piping Transitions.

The stress limits of Table ND-3321-1 shall apply to all portions of nozzles which lie within the limits of reinforcement given in ND-3334, except as provided for in ND-3324.14. Stresses in the extension of any nozzle beyond the limits of reinforcement shall be subject to the stress limits of ND-3600.

ND-3324.14

(a) Where a nozzle-to-shell junction is reinforced in accordance with the rules of ND-3334, the stresses in this region due to internal pressure may be considered to satisfy the limits of Table ND-3321-1. Under these conditions no analysis is required to demonstrate compliance for pressure induced stresses in the nozzle region.

(b) Where external piping loads are specified, membrane plus bending stresses due to these loads shall be calculated in the nozzle, and membrane stresses shall be calculated in the local nozzle-to-shell region. These stresses, in conjunction with pressure induced stresses, shall meet the limits of Table ND-3321-1 for $(\sigma_m \text{ or } \sigma_L) + \sigma_b$. In this case the pressure induced stresses in the $(\sigma_m \text{ or } \sigma_L) + \sigma_b$ category may be assumed to be no greater than the limit for σ_m in Table ND-3321-1 for a given condition.

ND-3324.15 Other Loadings.

When necessary, vessels shall be provided with stiffeners or other additional means of support to prevent overstress or large distortions under the external loadings listed in ND-3111 other than pressure and temperature.

ND-3325 Flat Heads and Covers

4 Special consideration shall be given to the design of shells, nozzle neck, or flanges to which noncircular heads or cover are attached.

The minimum thickness of unstayed flat heads, cover plates, and blind flanges shall conform to the requirements given in this paragraph. These requirements apply to both circular and noncircular⁴ heads and covers. Some acceptable types of flat heads and covers are shown in Fig. ND-3325-1. In this figure, the dimensions of the component parts and the dimensions of the welds

Page 74

are exclusive of extra metal required for corrosion allowance.

ND-3325.1 Nomenclature.

The symbols used are defined as follows:

C	= a factor depending upon the method of attachment of head, shell dimensions, and other items as listed in ND-3325.3, dimensionless
D	= long span of noncircular heads or covers measured perpendicular to short span, in.
d	= diameter, or short span, measured as indicated in Fig. ND-3325-1, in.
h_G	= gasket moment arm, equal to the radial distance from the center line of the bolts to the line of the gasket reaction, as shown in Table XI-3221.1-2, in.
L	= perimeter of noncircular bolted head measured along the centers of the bolt holes, in.
l	= length of flange of flanged heads, measured from the tangent line of knuckle, as indicated in Fig. ND-3325-1 sketches (a) and (c), in.
m	= the ratio t_r/t_s
P	= Design Pressure, psi
r	= inside corner radius on a head formed by flanging or forging, in.
S	= maximum allowable stress value, psi, from Tables 1A and

1B, Section II, Part D, Subpart 1

t	= minimum required thickness of flat head or cover, exclusive of corrosion allowance, in.
t_f	= actual thickness of the flange on a forged head, at the large end, exclusive of corrosion allowance, as indicated in Fig. ND-3325-1 sketches (b-1) and (b-2), in.
t_h	= actual thickness of flat head or cover, exclusive of corrosion allowance, in.
t_p	= the smallest dimension from the face of the head to the edge of the weld preparation, in.
t_r	= required thickness of seamless shell, for pressure, in.
t_s	= actual thickness of shell, exclusive of corrosion allowance, in.
t_w	= thickness through the weld joining the edge of a head to the inside of a vessel, as indicated in Fig. ND-3325-1 sketch (g), in.
t_1	= throat dimension of the closure weld, as indicated in Fig. ND-3325-1 sketch (r), in.
W	= total bolt load, lb, given for circular heads for Formulas (3) and (4), XI-3223
Z	= a factor of noncircular heads and covers that depends on the ratio of short span to long span (ND-3325.2), dimensionless

ND-3325.2 Thickness.

The thickness of unstayed flat heads, covers, and blind flanges shall conform to one of the following four requirements.⁵

(a) Circular blind flanges of ferrous materials conforming to ANSI B16.5 shall be acceptable for the diameters and pressure-temperature ratings in Tables 2 to 8 of that Standard, when of the types shown in Fig. ND-3325-1 sketches (j) and (k).

(b) The minimum required thickness of flat unstayed circular heads, covers, and blind flanges shall be calculated by Eq. (4):

$$(4) t = d \sqrt{CP/S}$$

except when the head, cover, or blind flange is attached by bolts causing an edge moment [Fig. ND-3325-1 sketches (j) and (k)], in which case the thickness shall be calculated by Eq. (5):

$$(5) t = d \sqrt{CP/S + 1.9 W h_G / S d^3}$$

When using Eq. (5), the thickness t shall be calculated for both Service Loadings and gasket seating and the greater of the two values shall be used. For Service Loadings, the value of P shall be the Design Pressure and the values of S at the Design Temperature and W from Eq. (3) of XI-3223(c) shall be used. For gasket seating, P equals zero and the values of S at atmospheric temperature and W from Eq. (4) of XI-3223 shall be used.

(c) Flat unstayed heads, covers, or blind flanges may be square, rectangular, elliptical, obround, segmental, or otherwise noncircular. Their required thickness shall be calculated by Eqs. (6) and (7):

$$(6) t = d \sqrt{ZCP/S}$$

where

(7)

with the limitation that Z need not be greater than 2.5.

5 The equation provide safe construction as far as stress is concerned. Greater thicknesses may be necessary if deflection would cause leakage at threaded or gasketed joints.

(d) Equation (6) does not apply to noncircular heads, covers, or blind flanges attached by bolts causing a bolt edge moment [Fig. ND-3325-1 sketches (j) and (k)]. For noncircular heads of this type, the required thickness shall be calculated by the following equation:

Page 75

Page 76

FIG. ND-3325-1 SOME ACCEPTABLE TYPES OF UNSTAYED FLAT HEADS AND COVERS
The Above Illustrations Are Diagrammatic Only. Other Designs That Meet The Requirements of ND-3325 Are Acceptable.

FIG. ND-3325-1 SOME ACCEPTABLE TYPES OF UNSTAYED FLAT HEADS AND COVERS

$$(8) t = d \sqrt{ZCP/S + 4 W h_G / S L d^2}$$

When using Eq. (8), the thickness t shall be calculated in the same way as specified above for Eq. (5).

ND-3325.3 Values of C .

For the types of construction shown in Fig. ND-3325-1, the minimum values of C to be used in Eqs. (4), (5), (6), and (8) are given in (a) through (n) below.

(a) In sketch (a), $C = 0.17$ for flanged circular and noncircular heads forged integral with or butt welded to the vessel with an inside corner radius not less than three times the required head thickness, with no special requirement with regard to length of flange.

(1) $C = 0.10$ for circular heads, when the flange length for heads of the above design is not less than:

$$l = \left(1.1 - 0.8 \frac{t_s^2}{t_h^2} \right) \sqrt{d t_h}$$

(2) $C = 0.10$ for circular heads, when the flange length l is less than the requirement in (a)(1) above but the shell thickness is not less than:

$$t_s = 1.12 t_h \sqrt{1.1 - l / \sqrt{d t_h}}$$

for a length of at least $2\sqrt{d t_s}$.

(3) When $C = 0.10$ is used, the taper shall be 1:4.

(b) In sketch (b-1), $C = 0.17$ for forged circular and noncircular heads integral with or butt welded to the vessel, where the flange thickness is not less than two times the shell thickness, the corner radius on the inside is not less than three times the flange thickness, and the welding meets all the requirements for circumferential joints given in ND-4000.

(c) In sketch (b-2), $C = 0.33m$ but not less than 0.3 for forged circular and noncircular heads integral with or butt welded to the vessel, where the flange thickness is not less than the shell thickness, the corner radius on the inside is not less than 1.5 times the flange thickness, and the welding meets all the requirements for circumferential joints given in ND-4000. [See Fig. ND-4243.1-1 sketches (a) and (b) for the special case where t_f equals t_s .]

(d) In sketch (c), $C = 0.13$ for circular heads lap-welded or brazed to the shell with corner radius not less than $3t$ and l not less than required by (a)(1) above and the requirements of ND-3358 are met.

(1) $C = 0.20$ for circular and noncircular lap-welded or brazed construction as above but with no special requirement with regard to l .

(2) $C = 0.20$ for circular flanged plates screwed over the end of the vessel with inside corner radius not less than $3t$, in which the design of the threaded joint against failure by shear, tension, or compression, resulting from the end force due to pressure, is based on a factor of safety of at least 4 and the threaded parts are at least as strong as the threads for standard piping of the same diameter. Seal welding may be used, if desired.

(e) In sketch (d), $C = 0.13$ for integral flat circular heads when the dimension d does not exceed 24 in., the ratio of thickness of the head to the dimension d is not less than 0.05 nor greater than 0.25, the head thickness t_h is not less than the shell thickness t_s , the inside corner radius is not less than $0.25t$, and the construction is obtained by special techniques of upsetting and spinning the end of the shell, such as employed in closing header ends.

(f) In sketches (e), (f), and (g), $C = 0.33m$ but not less than 0.2 for circular plates, welded to the inside of a vessel, and otherwise meeting the requirements for the respective types of welded vessels. If a value of m less than 1 is used in calculating t , the shell thickness t_s shall be maintained along a distance inwardly from the inside face of the head equal to at least $2\sqrt{dt_s}$. The throat thickness of the fillet welds in sketches (e) and (f) shall be at least $0.7t_s$. The size of the weld t_w in sketch (g) shall be not less than two times the required thickness of a seamless shell nor less than 1.25 times the nominal shell thickness, but need not be greater than the head thickness; the weld shall be deposited in a welding groove with the root of the weld at the inner face of the head as shown in the figure.

For noncircular plates, welded to the inside of a vessel and otherwise meeting the requirements for the respective types of welded vessels, $C = 0.33$. The throat thickness of the fillet welds in sketches (e) and (f) shall be at least $0.7t_s$. The size of the weld t_w in sketch (g) shall be not less than two times the required thickness of a seamless shell nor less than 1.25 times the nominal shell thickness, but need not be greater than the head thickness; the weld shall be deposited in a welding groove with the root of the weld at the inner face of the head as shown in the figure.

(g) In sketch (h), $C = 0.33$ for circular plates welded to the end of the shell when t_s is at least $1.25t_r$ and the weld details conform to the requirements of ND-3358.3(e) and Fig. ND-4243-1 sketches (a) to (g), inclusive.

(h) In sketch (i), $C = 0.33m$ but not less than 0.3 for circular plates if an inside fillet weld with minimum throat thickness of $0.7t_s$ is used and the details of the

Page 77

outside weld conform to the requirements of ND-3358.3(e) and Fig. ND-4243-1 sketches (a) to (g), inclusive, in which the inside weld can be considered to contribute an amount equal to t_s to the sum of the dimensions a and b .

(i) In sketches (j) and (k), $C = 0.2$ for circular and noncircular heads and covers bolted to the vessel as indicated in the figures. Note that Eq. (5) or (8) shall be used because of the extra moment applied to the cover by bolting. When the cover plate is grooved for a peripheral gasket, as shown in sketch (k), the net cover plate thickness under the groove or between the groove and the outer edge of the cover plate shall be not less than

$$d\sqrt{1.27Wh_G\bar{S}d^3}$$

for circular heads and covers, nor less than

d

$$d\sqrt{4Wh_G/SLd}$$

for noncircular heads and covers.

(j) In sketches (m), (n), and (o), $C = 0.2$ for a circular plate inserted into the end of a vessel and held in place by a positive mechanical locking arrangement and when all possible means of failure (either by shear, tension, compression, or radial deformation, including flaring, resulting from pressure and differential thermal expansion) are resisted using stresses consistent with this Article. Seal welding may be used, if desired.

(k) In sketch (p), $C = 0.17$ for circular and noncircular covers bolted with a full face gasket to shells, flanges, or side plates.

(l) In sketch (q), $C = 0.50$ for circular plates screwed into the end of a vessel having an inside diameter d not exceeding 12 in. or for heads having an integral flange screwed over the end of a vessel having an inside diameter d not exceeding 12 in. (305 mm) and when the design of the threaded joint against failure by shear, tension, compression, or radial deformation, including flaring, resulting from pressure and differential thermal expansion, is based on stresses consistent with this Subsection. If a tapered pipe thread is used, the requirements of ND-3361.3 shall also be met. Seal welding may be used, if desired.

(m) In sketch (r), $C = 0.33$ for circular plates having a dimension d not exceeding 18 in. (457 mm) inserted into the vessel as shown and otherwise meeting the requirements for the respective types of welded vessels. The end of the vessel shall be crimped over at least 30 deg, but not more than 45 deg. The crimping may be done cold only when this operation will not injure the metal. The throat of the weld shall be not less than the thickness of the flat head or shell, whichever is greater.

(n) In sketch (s), $C = 0.33$ for circular beveled plates having a diameter d not exceeding 18 in. (457 mm), inserted into a vessel, the end of which is crimped over at least 30 deg but not more than 45 deg and when the undercutting for seating leaves at least 80% of the shell thickness. The beveling shall be not less than 75% of the head thickness. The crimping shall be done when the entire circumference of the cylinder is uniformly heated to the proper forging temperature for the material used. For this construction, the ratio t/d shall be not less than the ratio P/S nor less than 0.05. The maximum allowable pressure for this construction shall not exceed $P = S/5d$.

(o) In Fig. ND-4243.1-1, $C = 0.33m$, but not less than 0.3 when the dimensional requirements of ND-3358.4 are met.

ND-3326 Spherically Dished Covers With Bolting Flanges

ND-3326.1 Nomenclature.

The symbols used are defined as follows:

t	= minimum required thickness of head plate after forming, in.
L	= inside spherical or crown radius, in.
r	= inside knuckle radius, in.
P	= Design Pressure, psi
S	= maximum allowable stress value, psi
T	= flange thickness, in.
M_o	= the total moment, in.-lb, determined as in XI-3230 for heads concave to pressure, and XI-3260 for heads convex to pressure; except that, for heads of the type shown in Fig. ND-3326.1-1 sketch (d), H_D and h_D shall be as defined below, and an additional moment $H_r h_r$ shall be included ⁶
H_r	= radial component of the membrane load in the spherical segment = $H_D \cot \beta_1$, lb, acting at the intersection of the inside of the flange ring with the center line of the dished cover thickness

h_r

= lever arm of H_r about centroid of flange ring, in.

H_D

= axial component of the membrane load in the spherical segment, lb, acting at the inside of the flange ring

$$= 0.785B^2P$$

6 Since $H_r h_r$ in some cases will subtract from the total moment, the moment in the flange ring when the internal pressure is zero may be determining loading for the flange design.

Page 78

h_D

= radial distance from the bolt circle to the inside of the flange ring, in.

β_1

= angle formed by the tangent to the center line of the dished cover thickness at its point of intersection with the flange ring, and a line perpendicular to the axis of the dished cover where

$$\beta_1 = \arcsin \left(\frac{B}{2L + t} \right)$$

A

= outside diameter of flange, in.

B

= inside diameter of flange, in.

C

= bolt circle diameter, in.

FIG. ND-3326.1-1 SPHERICALLY DISHED COVERS WITH BOLTING FLANGES

FIG. ND-3326.1-1 SPHERICALLY DISHED COVERS WITH BOLTING FLANGES

ND-3326.2 Spherically Dishd Heads With Bolting Flanges.

Circular spherically dishd heads with bolting flanges, both concave and convex to the pressure, and conforming to the several types illustrated in Fig. ND-3326.1-1, shall be designed in accordance with the requirements of (a) through (d) below. For heads convex to pressure, the spherical segments shall be thickened, if necessary, to meet the requirements of ND-3133. The actual value of the total moment M_o may calculate to be either plus or minus for both the heads concave to pressure and the heads convex to pressure. However, for use in all of the formulas which follow, the absolute values for both P and M_o shall be used.

(a) Heads of the Type Shown in Fig. ND-3326.1-1 Sketch (a)

- (1) The thickness of the head t shall be determined by the appropriate equation in ND-3324.
- (2) The head radius L or the knuckle radius r shall not exceed the limitations given in ND-3324.
- (3) The flange shall comply at least with the requirements of Fig. XI-3120-1 and shall be designed in accordance with the applicable provisions of Appendix XI. Within the range of ANSI B16.5, the flange facings and drillings should conform to those Standards and the thickness specified therein shall be considered as a minimum requirement.

(b) Heads of the Type Shown in Fig. ND-3326.1-1 Sketch (b)

- (1) Head thickness:

$$t = \frac{5PL}{6S}$$

(2) Flange thickness T :

For ring gasket:

Page 79

$$T = \sqrt{\frac{M_o}{SB} \left(\frac{A + B}{A - B} \right)}$$

For full face gasket:

$$T = 0.6 \sqrt{\frac{P}{S} \left[\frac{B(A + B)(C - B)}{(A - B)} \right]}$$

NOTE: The radial components of the membrane load in the spherical segment are assumed to be resisted by its flange.

Within the range of ANSI B16.5, the flange facings and drillings should conform to those Standards, and the thickness specified therein shall be considered as a minimum requirement.

(c) Heads of the Type Shown in Fig. ND-3326.1-1 Sketch (c)

(1) Head thickness:

$$t = \frac{5PL}{6S} \quad (9)$$

(9)

(2) Flange thickness for ring gaskets shall be calculated as follows:

(a) for heads with round bolting holes:

$$T = Q + \sqrt{\frac{1.875 M_o(C + B)}{SB(7C - 5B)}} \quad (10)$$

(10)

where

$$Q = \frac{PL}{4S} \left(\frac{C + B}{7C - 5B} \right) \quad (11)$$

(11)

(b) for heads with bolting holes slotted through the edge of the head:

$$T = Q + \sqrt{\frac{1.875 M_o(C + B)}{SB(3C - B)}} \quad (12)$$

(12)

where

$$Q = \frac{PL}{4S} \left(\frac{C + B}{3C - B} \right) \quad (13)$$

(13)

(3) Flange thickness for full face gaskets shall be calculated by the following equation:

$$T = Q + \sqrt{Q^2 + \frac{3BQ(C - B)}{L}} \quad (14)$$

(14)

The value of Q in Eq. (14) is calculated by Eq. (11) for round bolting holes or by Eq. (13) for bolting holes slotted through the edge of the head [see (c)(2) above].

(4) The required flange thickness shall be T as calculated in (c)(2) or (c)(3) above, but in no case less than the value of t calculated in (1) above.

(d) Heads of the Type Shown in Fig. ND-3326.1-1 Sketch (d)

(1) Head thickness:

$$t = \frac{5PL}{6S} \quad (15)$$

(15)

(2) Flange thickness:

$$T = F + \sqrt{F^2 + J} \quad (16)$$

(16)

where

$$F = \frac{PB \sqrt{4L^2 - B^2}}{8S(A - B)} \quad (17)$$

(17)

and

$$J = \left(\frac{M_o}{SB} \right) \left(\frac{A + B}{A - B} \right) \quad (18)$$

(18)

NOTE: These equations are approximate in that they do not take into account continuity between the flange ring and the dished head. A more exact method of analysis which takes this into account may be used. Such a method may parallel the method of analysis and allowable stresses for flange design in Appendix XI. The dished portion of a cover designed under this rule may, if welded, require evaluation of any welded joint.

ND-3327 Quick Actuating Closures

Closures other than the multibolted type designed to provide access to the contents space of a component shall have the locking mechanism or locking device so designed that failure of any one locking element or component in the locking mechanism cannot result in the failure of all other locking elements and the release of the closure. Quick actuating closures shall be so designed and installed that it may be determined by visual external observation that the holding elements are in good condition and that their locking elements, when the closure is in the closed position, are in full engagement.

ND-3327.1 Positive Locking Devices.

Quick actuating closures that are held in position by positive locking devices and that are fully released by partial rotation or limiting movement of the closure itself or the locking

Page 80

mechanism and any closure that is other than manually operated shall be so designated that when the vessel is installed the conditions of (a) through (c) below are met.

(a) The closure and its holding elements are fully engaged in their intended operating position before pressure can be built up in the vessel.

(b) Pressure tending to force the closure clear of the vessel will be released before the closure can be fully opened for access.

(c) In the event that compliance with (a) and (b) is not inherent in the design of the closure and its holding elements, provision shall be made so that devices to accomplish this can be added when the vessel is installed.

ND-3327.2 Manual Operation.

Quick actuating closures that are held in position by a locking device or mechanism that requires manual operation and are so designed that there will be leakage of the contents of the vessel prior to disengagement of the locking elements and release of closure need not satisfy ND-3327.1, but such closures shall be equipped with an audible or visible warning device that will serve to warn the operator if pressure is applied to the vessel before the closure and its holding elements are fully engaged in their intended position and further will serve to warn the operator if an attempt is made to operate the locking mechanism or device before the pressure within the vessel is released.

ND-3327.3 Pressure Indicating Device.

When installed, all vessels having quick actuating closures shall be provided with a pressure indicating device visible from the operating area.

ND-3328 Combination Units

When a vessel consists of more than one independent chamber, operating at the same or different pressures and temperatures, each such chamber shall be designed and constructed to withstand the most severe condition of coincident pressure and temperature expected in normal service.

ND-3329 Braced and Stayed Surfaces, Staybolts, and Ligaments

ND-3329.1 Braced and Stayed Surfaces

(a) The minimum thickness and maximum allowable pressure for braced and stayed flat plates and those parts which, by these rules, require staying as flat plates with braces or staybolts of uniform diameter symmetrically spaced shall be calculated by the following equations:

$$t = p \sqrt{\frac{P}{SC}} \quad (19)$$

(19)

$$P = \frac{t^2 SC}{p^2} \quad (20)$$

(20)

where

t

= minimum thickness of plate, exclusive of corrosion allowance, in.

P	= Design Pressure, psi
S	= maximum allowable stress value, psi, given in Tables 1A and 1B, Section II, Part D, Subpart 1
p	= maximum pitch measured between straight lines passing through the centers of the staybolts in the different rows, which lines may be horizontal, vertical, or inclined, in.
C	= 2.1 for welded stays or stays screwed through plates not over $\frac{7}{16}$ in. in thickness with ends riveted over = 2.2 for welded stays or stays screwed through plates over $\frac{7}{16}$ in. in thickness with ends riveted over = 2.5 for stays screwed through plates and fitted with single nuts outside of plate or with inside and outside nuts, omitting washers = 2.8 for stays with heads not less than 1.3 times the diameter of the stays screwed through plates, or made a taper fit and having the heads formed on the stays before installing them and not riveted over = 3.2 for stays fitted with inside and outside nuts and outside washers where the diameter of washers is not less than $0.4p$ and thickness not less than t

(b) The minimum thickness of plates to which stays may be applied, in other than cylindrical or spherical outer shell plates, shall be $\frac{5}{16}$ in. (8 mm) except for welded construction (ND-3329.3).

(c) If a stayed jacket extends completely around a cylindrical or spherical vessel, or completely covers a formed head, it shall meet the requirements given in (a) above and shall also meet the applicable requirements for shells or heads (ND-3324).

(d) When two plates are connected by stays and but one of these plates requires staying, the value of C shall be governed by the thickness of the plate requiring staying.

FIG. ND-3329.1(e)-1 ACCEPTABLE PROPORTIONS FOR ENDS OR THROUGH STAYS

FIG. ND-3329.1(e)-1 ACCEPTABLE PROPORTIONS FOR ENDS OR THROUGH STAYS

(e) The acceptable proportions for the ends of through stays with washers are indicated in Fig. ND-3329.1(e)-1.

(f) The maximum pitch shall be $8\frac{1}{2}$ in. (216 mm), except that for welded-in staybolts the pitch may be greater, provided it does not exceed 15 times the diameter of the staybolt.

(g) When the staybolting of shells is unsymmetrical by reason of interference with butt straps or other construction, it is permissible to consider the load carried by each staybolt as the area calculated by taking the distance from the center of the spacing on one side of the bolt to the center of the spacing on the other side.

ND-3329.2 Threaded Staybolts

(a) The ends of staybolts or stays screwed through the plate shall extend beyond the plate not less than two threads when installed, after which they shall be riveted over or upset by an equivalent process without excessive scoring of the plates, or they shall be fitted with threaded nuts through which the bolt or stay shall extend.

(b) The ends of steel stays upset for threading shall be fully annealed.

ND-3329.3 Welded Stayed Construction.

For welded stayed construction, the provisions of ND-4470 and ND-5260 shall be met in addition to the requirements of (a) through (d) below.

(a) Welded-in staybolts shall meet the requirements of (1) through (4) below.

(1) The arrangement shall conform to one of those illustrated in Fig. ND-4470-1.

(2) The required thickness of the plate shall not exceed $1\frac{1}{2}$ in. (38 mm) but, if greater than $\frac{3}{4}$ in. (19 mm), the staybolt pitch shall not exceed 20 in. (508 mm).

(3) The provisions of ND-3329.1 and ND-3329.4 shall be met.

(4) The required area of the staybolt shall be determined in accordance with ND-3329.5.

(b) Welded stays, as shown in Fig. ND-4470-1, may be used to stay jacketed vessels provided the requirements of (1) through (8) below are met.

(1) The pressure does not exceed 300 psi (2070 kPa).

(2) The required thickness of the plate does not exceed $\frac{1}{2}$ in. (13 mm).

(3) The size of the fillet welds is not less than the plate thickness.

(4) The inside welds are properly inspected before the closing plates are attached.

(5) The allowable load on the fillet welds is computed in accordance with ND-3356(c).

(6) The maximum diameter or width of the hole in the plate does not exceed $1\frac{1}{4}$ in. (32 mm).

(7) The welders are qualified under the rules of Section IX.

(8) The maximum spacing of stays is determined by the equation in ND-3329.1(a), using:

C	$= 2.1$ if either plate is not over $\frac{7}{16}$ in. (11 mm) thick
C	$= 2.2$ if both plates are over $\frac{7}{16}$ in. (11 mm) thick

(c) Welded stayed construction, consisting of a dimpled or embossed plate welded to another like plate or to a plain plate, may be used provided the requirements of (1) through (4) below are met.

(1) The pressure does not exceed 300 psi (2070 kPa).

(2) The welded attachment is made by fillet welds around holes or slots as shown in Fig. ND-4470-1 and is calculated in accordance with ND-4470.

(3) The maximum allowable pressure of the dimpled or embossed components is established in accordance with the requirements of ND-6900.

(4) The plain plate, if used, shall meet the requirements for braced and stayed surfaces.

(d) The welds need not be radiographed, nor need they be postweld heat treated unless the vessel is required to be postweld heat treated.

[98]

ND-3329.4 Location of Staybolts

(a) The distance from the edge of a staybolt hole to the edge of a flat stayed plate shall not be greater than the pitch of the stays.

FIG. ND-3329.6(b)-1 EXAMPLE OF TUBE SPACING WITH PITCH OF HOLES EQUAL IN EVERY ROW

FIG. ND-3329.6(b)-1 EXAMPLE OF TUBE SPACING WITH PITCH OF HOLES EQUAL IN EVERY ROW

(b) When the edge of a flat stayed plate is flanged, the distance from the center of the outermost stays to the inside of the supporting flange shall not be greater than the pitch of the stays plus the inside radius of the flange.

ND-3329.5 Dimensions of Staybolts

(a) The required area of a staybolt at its minimum cross section⁷ and exclusive of any allowance for corrosion shall be obtained by dividing the load on the staybolt, computed in accordance with (b) below, and by increasing the allowable stress value by a factor of 1.10 for the material used (Tables 1A and 1B, Section II, Part D, Subpart 1).

(b) The area supported by a stay shall be computed on the basis of the full pitch dimensions, with a deduction for the area occupied by the stay. The load carried by a stay is the product of the area supported by the stay and the maximum allowable pressure.

(c) Stays made of parts joined by welding shall be designed using a joint efficiency of 0.60 for the weld.

ND-3329.6 Ligaments

(a) The symbols used in the equations and chart of this paragraph are defined as follows:

p	= longitudinal pitch of tube holes, in.
p_1	= unit length of ligament, in.

p'	= diagonal pitch of tube holes, in.
d	= diameter of tube holes, in.
n	= number of tube holes in length p_1

(b) When a cylindrical shell is drilled for tubes in a line parallel to the axis of the shell for substantially the full length of the shell as shown in Figs. ND-3329.6(b)-1 through ND-3329.6(b)-3, the efficiency of the ligaments between the tube holes shall be determined as follows:

7 The minimum cross section is usually at the root of the thread.

FIG. ND-3329.6(b)-2 EXAMPLE OF TUBE SPACING WITH PITCH OF HOLES UNEQUAL IN EVERY SECOND ROW

FIG. ND-3329.6(b)-2 EXAMPLE OF TUBE SPACING WITH PITCH OF HOLES UNEQUAL IN EVERY SECOND ROW

FIG. ND-3329.6(b)-3 EXAMPLE OF TUBE SPACING WITH PITCH OF HOLES VARYING IN EVERY SECOND AND THIRD ROW

FIG. ND-3329.6(b)-3 EXAMPLE OF TUBE SPACING WITH PITCH OF HOLES VARYING IN EVERY SECOND AND THIRD ROW

(1) when the pitch of the tube holes on every row is equal [Fig. ND-3329.6(b)-1], the formula is $(p-d)/p$ = efficiency of ligament;

(2) when the pitch of tube holes on any one row is unequal [Figs. ND-3329.6(b)-2 and ND-3329.6(b)-3], the equation is $(p_1 - nd)/p_1$ = efficiency of ligament.

(c) The strength of ligaments between tube holes measured circumferentially shall be at least 50% of the strength of ligaments of similar dimensions taken in a line parallel to the axis of the cylindrical shell.

(d) When a cylindrical shell is drilled for tube holes so as to form diagonal ligaments, as shown in Fig. ND-3329.6(d)-1, the efficiency of these ligaments shall be that given by the diagram in Fig. ND-3329.6(d)-2. The pitch of tube holes shall be measured either on the flat plate before rolling or on the middle line of the plate after rolling. To use the diagram in Fig. ND-3329.6(d)-2, compute the value of p/p_1 and also the efficiency of the longitudinal ligament. Next find in the diagram the vertical line corresponding to the longitudinal efficiency of the ligament and follow this line vertically to the point where it intersects the diagonal line representing the ratio of p/p_1 . Then

Page 83

project this point horizontally to the left and read the diagonal efficiency of the ligament on the scale at the edge of the diagram. The shell thickness and the maximum allowable pressure shall be based on the ligament that has the lower efficiency.

FIG. ND-3329.6(d)-1 EXAMPLE OF TUBE SPACING WITH TUBE HOLES ON DIAGONAL LINES

FIG. ND-3329.6(d)-1 EXAMPLE OF TUBE SPACING WITH TUBE HOLES ON DIAGONAL LINES

(e) When tube holes in a cylindrical shell are arranged in symmetrical groups which extend a distance greater than the inside diameter of the shell along lines parallel to the axis and the same spacing is used for each group, the efficiency for one of the groups shall be not less than the efficiency on which the maximum allowable pressure is based.

(f) The average ligament efficiency in a cylindrical shell, in which the tube holes are arranged along lines parallel to the axis with either uniform or nonuniform spacing, shall be computed by the following rules and shall satisfy the requirements of both (1) and (2) below.⁸

(1) For a length equal to the inside diameter of the shell for the position which gives the minimum efficiency, the efficiency shall be not less than that on which the maximum allowable pressure is based. When the diameter of the shell exceeds 60 in. (1520 mm), the length shall be taken as 60 in. (1520 mm) in applying this rule.

8 The rules in this paragraph apply to ligaments between tube holes and not to single openings. They may give lower efficiencies in some cases than those for symmetrical groups which extend a distance greater than the inside diameter of the shell as covered in (c). When this occurs, the efficiencies computed by the rules under (b) shall govern.

(2) For a length equal to the inside radius of the shell for the position which gives the minimum efficiency, the efficiency shall be not less than 80% of that on which the maximum allowable pressure is based. When the radius of the shell exceeds 30 in. (762 mm), the length shall be taken as 30 in. (762 mm) in applying this rule.

(g) For holes which are not in line, placed longitudinally along a cylindrical shell, the rules in (f) above for calculating efficiency shall hold, except that the equivalent longitudinal width of a diagonal ligament shall be used. To obtain the equivalent width, the longitudinal pitch of the two holes having a diagonal ligament shall be multiplied by the efficiency of the diagonal ligament. The efficiency to be used for the diagonal ligaments is given in Fig. ND-3329.6(g)-1.

ND-3330 OPENINGS AND REINFORCEMENT⁹

ND-3331 General Requirements for Openings

(a) Openings¹⁰ in cylindrical or conical portions of vessels or in formed heads shall preferably be circular, elliptical, or obround.¹¹ When the long dimension of an elliptical or obround opening exceeds twice the short dimensions, the reinforcement across the short dimensions shall be increased as necessary to provide against excessive distortion due to twisting moment.

(b) Openings may be of other shapes than those given in (a) above, and all corners shall be provided with a suitable radius. When the openings are of such proportions that their strength cannot be computed with assurance of accuracy or when doubt exists as to the safety of a vessel with such openings, the part of the vessel affected shall be subjected to a proof hydrostatic test as prescribed in ND-6900.

(c)(1) The rules for reinforcement of openings given in ND-3330 are intended to apply to openings not exceeding the following:

(a) for vessels 60 in. (1520 mm) diameter and less: one-half the vessel diameter but not to exceed 20 in. (508 mm);

9 The rules governing openings as given in this Subsection are based on the stress intensification created by the existence of a hole in an otherwise symmetrical section. They are based on experience with vessels designed with design factors of 4 and 5 applied to the ultimate strength of the shell material. External loadings such as those due to the thermal expansion or unsupported weight of connecting piping have not been evaluated. These factors should be given attention in unusual designs or under conditions of cyclic loading.

10 The opening made by a pipe or a circular nozzle, the axis of which is not perpendicular to the vessel wall or head, may be considered an elliptical opening for design purposes.

11 An obround opening is one which is formed by two parallel sides and semicircular ends.

Page 84

Page 85

FIG. ND-3329.6(d)-2 DIAGRAM FOR DETERMINING THE EFFICIENCY OF LONGITUDINAL AND DIAGONAL LIGAMENTS BETWEEN OPENINGS IN CYLINDRICAL SHELLS

FIG. ND-3329.6(d)-2 DIAGRAM FOR DETERMINING THE EFFICIENCY OF LONGITUDINAL AND DIAGONAL LIGAMENTS BETWEEN OPENINGS IN CYLINDRICAL SHELLS

FIG. ND-3329.6(g)-1 DIAGRAM FOR DETERMINING EQUIVALENT LONGITUDINAL EFFICIENCY OF DIAGONAL LIGAMENTS

FIG. ND-3329.6(g)-1 DIAGRAM FOR DETERMINING EQUIVALENT LONGITUDINAL EFFICIENCY OF DIAGONAL LIGAMENTS

(b) for vessels over 60 in. (1520 mm) diameter: one-third the vessel diameter but not to exceed 40 in. (1000 mm).

(2) Larger openings shall be given special attention. Two-thirds of the required reinforcement shall be within $\frac{1}{2}r$ parallel to the vessel surface and measured from the edge of the opening, where r is the radius of the finished opening. The limit normal to the vessel wall is the smaller of the limits specified in ND-3334.2. Special consideration shall be given to the fabrication details used and examination employed. Reinforcement often may be advantageously obtained by use of heavier shell plate for a vessel course or inserted locally around the opening. Welds may be ground to concave contour and the inside corners of the opening rounded to a generous radius to reduce stress concentrations.

(d) All references to dimensions in ND-3330 apply to the finished dimensions, excluding material added as corrosion allowance.

(e) Any type of opening may be located in a welded joint.

ND-3332 Reinforcement Requirements for Openings in Shells and Formed Heads

ND-3332.1 Openings Not Requiring Reinforcement.

Reinforcement shall be provided in amount and distribution such that the requirements for area of reinforcement are satisfied for all planes through the center of the opening and normal to the surface of the vessel, except that single circular openings need not be provided with reinforcement if the openings have diameters equal to or less than NPS 2 (DN 50).

ND-3332.2 Required Area of Reinforcement.

The total cross-sectional area of reinforcement A required in any given plane for a vessel under internal pressure shall not be less than:

$$A = dt_r F$$

where

d

= finished diameter of a circular opening or finished dimension (chord length) of an opening on the plane being considered for elliptical and obround openings in corroded condition, in.

F

= a correction factor which compensates for the variation in pressure stresses on different planes with respect to the axis of a vessel. A value of 1.00 shall be used for all configurations except that Fig. ND-3332.2-1 may be used for integrally reinforced openings in cylindrical shells and cones.

t_r

= the required thickness of a shell or head computed in accordance with the rules of this Article for the Design Pressure, in., except that:

(a) when the opening and its reinforcement are entirely within the spherical portion of a torispherical head, t_r is the thickness required by ND-3324.8(b), using $E=1$ and $M=1$;

(b) when the opening is in a cone, t_r is the thickness required for a seamless cone of diameter D measured where the nozzle axis pierces the inside wall of the cone;

(c) when the opening and its reinforcement are in an ellipsoidal head and are located entirely within a circle the center of which coincides with the center of the head and the diameter of which is equal to 80% of the shell diameter, t_r is the thickness required for a seamless sphere of radius $K_1 D$, where D is the shell diameter and K_1 is given by Table

**FIG. ND-3332.2-1 CHART FOR DETERMINING
VALUE OF F**

TABLE ND-3332.2-1 VALUES OF SPHERICAL RADIUS FACTOR K_1

At least one-half of the required reinforcing shall be on each side of the center line of the opening.

ND-3332.3 Reinforcement for External Pressure

(a) The reinforcement required for openings in vessels designed for external pressure need only be 50% of that required in the equation for area in ND-3332.2 except t_r is the wall thickness required by the rules for components under external pressure.

(b) The reinforcement required for openings in each shell of a multiple walled vessel shall comply with (a) above when the shell is subject to external pressure and with ND-3332.2 when the shell is subject to internal pressure.

ND-3332.4 Reinforcement for Internal and External Pressure.

Reinforcement of vessels subject to both internal and external pressures shall meet the requirements of ND-3332.2 for internal pressure and of ND-3332.3 for external pressure.

ND-3333 Reinforcement Required for Openings in Flat Heads

(a) Flat heads that have an opening with a diameter that does not exceed one-half of the head diameter shall have a total cross-sectional area of reinforcement not less than that given by the equation:

$$A = 0.5 d t_r$$

where d is as defined in ND-3332.2 and t_r is the thickness, in., which meets the requirements of ND-3325 in the absence of the opening.

(b) As an alternative to (a) above, the thickness of flat heads may be increased to provide the necessary opening reinforcement as follows:

(1) in Eq. (4) of ND-3325.2, by using $2C$ or 0.75 in place of C , whichever is less;

(2) in Eq. (5) of ND-3325.2, by doubling the quantity under the square root sign.

(c) Flat heads that have an opening with a diameter that exceeds one-half of the head diameter or shortest span, as defined in ND-3325.1, shall be designed as follows.

(1) When the opening is a single, circular, centrally located opening and when the shell-head juncture is integrally formed or integrally attached by a full penetration weld similar to those shown in Fig. ND-3325-1 sketches (a), (b-1), (b-2), (d), or (g), the head shall be designed according to Appendix XIX and related parts of Appendix XI. The required head thickness which satisfies all the requirements of Appendix XIX also satisfies the intent of ND-3225. The opening in the head may have a nozzle which is integrally formed or integrally attached by a full penetration weld or it may be an opening without an attached nozzle or hub.

(2) When the opening is of any other type than that described in (1) above, no specific rules are given. Consequently, the requirements of ND-1100(c) shall be met.

ND-3334 Limits of Reinforcement

The boundaries of the cross-sectional area in any plane normal to the vessel wall and passing through the center of the opening and within which metal shall be located in order to have value as reinforcement are designated as the limits of reinforcement for that plane and are given in the following subparagraphs.

ND-3334.1 Limits of Reinforcement Along the Vessel Wall.

The limits of reinforcement, measured along the midsurface of the nominal wall thickness, shall meet the following.

(a) One hundred percent of the required reinforcement shall be within a distance on each side of the axis of the opening equal to the greater of the following:

(1) the diameter of the finished opening in the corroded condition;

(2) the radius of the finished opening in the corroded condition plus the sum of the thicknesses of the vessel wall and the nozzle wall.

(b) Two-thirds of the required reinforcement shall be within a distance on each side of the axis of the opening equal to the greater of the following:

(1) $r + 0.5\sqrt{Rt}$, where R is the mean radius, in., of shell or head, t is the nominal vessel wall thickness, in., r is the radius, in., of the finished opening in the corroded condition;

(2) the radius of the finished opening in the corroded condition plus two-thirds the sum of the thicknesses of the vessel wall and the nozzle wall.

ND-3334.2 Limits of Reinforcement Normal to the Vessel Wall.

The limits of reinforcement, measured normal to the vessel wall, shall conform to the contour of the surface at a distance from each surface equal to the lesser of (a) or (b) below:

(a) $2\frac{1}{2}$ times the nominal shell thickness less corrosion allowance;

(b) $2\frac{1}{2}$ times the nozzle wall thickness less corrosion allowance, plus the thickness of any added reinforcement exclusive of weld metal on the side of the shell under consideration.

ND-3335 Metal Available for Reinforcement

ND-3335.1 Openings.

Metal within the limits of reinforcement that may be considered to have reinforcing value shall be that given in (a) through (d) below:

(a) metal in the vessel wall over and above the thickness required to resist pressure and the thickness specified as corrosion allowance. The area in the vessel wall available as reinforcement is the larger of the values of A_1 given by:

$$A_1 = (E_1 t - F t_r) d$$

or

$$A_1 = 2(E_1 t - F t_r)(t + t_n)$$

(b) metal over and above the thickness required to resist pressure and the thickness specified as corrosion allowance in that part of a nozzle wall extending outside the vessel wall. The maximum area in the nozzle wall available as reinforcement is the lesser of the values of A_2 given by:

$$A_2 = (t_n - t_{rn}) 5t$$

or

$$A_2 = (t_n - t_{rn})(5t_n + 2t_e)$$

(c) all metal in the nozzle wall extending inside the vessel wall may be included after proper deduction for corrosion allowance on all the exposed surface is made. No allowance shall be taken for the fact that a differential pressure on an inwardly extending nozzle may cause opposing stress to that of the stress in the shell around the opening where:

A_1	= area in excess thickness in the vessel wall available for reinforcement, sq in. (ND-3334)
A_2	= area in excess thickness in the nozzle wall available for reinforcement, sq in. (ND-3334)
E_1	= 1 when an opening is in the plate or when the opening passes through a circumferential joint in a shell or cone exclusive of head-to-shell joints; or = the joint efficiency obtained from ND-3352 when any part of the opening passes through any other welded joint
F	= a correction factor which compensates for the variation in pressure stresses on different planes with respect to the axis of a vessel. A value of 1.00 shall be used for all configurations, except that Fig. ND-3332.2-1 may be used for integrally reinforced openings in cylindrical shells and cones.
t_e	= thickness of attached reinforcing pad or height of the largest 60 deg right triangle supported by the vessel and nozzle outside diameter projected surfaces and lying completely within the area of integral reinforcement, in. [Fig. ND-3335.1(b)-1]
t	= nominal thickness of the vessel wall, less corrosion allowance, in.
t_r	= required thickness of a seamless shell or head as defined in ND-3332.2, in.
t_n	= nominal thickness of nozzle wall, less corrosion allowance, in.
t_{rn}	= required thickness of a seamless nozzle wall, in.
d	= diameter in the plane under consideration of the finished opening in its corroded condition, in. (ND-3332.2)

(d) metal added as reinforcement and metal in attachment welds.

ND-3335.2 Reinforcement of Multiple Openings

(a) When any two openings in a group of two or more openings are spaced at less than two times their average diameter so that their limits of reinforcement overlap, the two openings shall be reinforced in the plane connecting the centers (Fig. ND-3335.2-1), in accordance with ND-3330 through ND-3336, with a combined reinforcement that has an area equal to the combined area of the reinforcements required for separate openings. No portion of the cross section is to be considered as applying to more than one opening, or

Page 89

to be evaluated more than once in a combined area. The following additional requirements shall also apply.

FIG. ND-3335.1(b)-1 SOME REPRESENTATIVE CONFIGURATIONS DESCRIBING THE t_e REINFORCEMENT DIMENSION

FIG. ND-3335.1(b)-1 SOME REPRESENTATIVE CONFIGURATIONS DESCRIBING THE t_e REINFORCEMENT

DIMENSION

GENERAL NOTES:

- (1) Hatched area represents overlapping of the reinforcement limits.
- (2) Each cross-section indicated by a straight line a-a must be investigated for adequacy of reinforcement.
- (3) Heavy circles represent openings, and light circles represent limits of reinforcement.

FIG. ND-3335.2-1 ARRANGEMENT OF MULTIPLE OPENINGS

FIG. ND-3335.2-1 ARRANGEMENT OF MULTIPLE OPENINGS

(1) When the distance between the centers of the openings is greater than $1\frac{1}{3}$ times their average diameter, the area of reinforcement between them shall be not less than 50% of the total required for these openings.

(2) When the distance between the centers of the openings is less than $1\frac{1}{3}$ times their average diameter, no credit for reinforcement shall be taken for any of the material between these openings, and the openings shall be reinforced as described in (b) below.

(b) Any number of adjacent openings, in any arrangement, may be reinforced for an assumed opening of a diameter enclosing all such openings. The diameter of the assumed opening shall not exceed the following:

- (1) for vessels 60 in. (1520 mm) diameter and less, one-half the vessel diameter, but not to exceed 20 in. (508 mm);
- (2) for vessels over 60 in. (1520 mm) diameter, one-third the vessel diameter, but not to exceed 40 in. (1000 mm).

(c) When a group of openings is reinforced by a thicker section butt welded into the shell or head, the edges of the inserted section shall be tapered as prescribed in ND-3361.

(d) When a series of two or more openings in a pressure vessel are arranged in a regular pattern, reinforcement of the openings may be provided in accordance with the requirements of ND-3329.6.

ND-3335.3 Flued Openings in Formed Heads

(a) Flued openings in formed heads made by inward or outward forming of the head plate shall meet the requirements

for reinforcement in ND-3332.

(b) The minimum depth of flange of a flued opening exceeding 6 in. (152 mm) in any inside dimension, when not stayed by an attached pipe or flue, shall equal $3t_r$ or $(t_r + 3)$ in., whichever is less, where t_r is the required head thickness. The depth of flange shall be determined by placing a straight edge across the side opposite the flued opening along the major axis and measuring from the straight edge to the edge of the flanged opening [Fig. ND-3335.3(b)-1].

(c) The minimum width of bearing surface for a gasket on a self-sealing flued opening shall be in accordance with ND-3363.7.

Page 91

Minimum depth of flange; the smaller of $3t_r$ or $t_r + 3$ in. when d exceeds 6 in.

FIG. ND-3335.3(b)-1 MINIMUM DEPTH FOR FLANGE OF FLUED OPENINGS

FIG. ND-3335.3(b)-1 MINIMUM DEPTH FOR FLANGE OF FLUED OPENINGS

ND-3336 Strength of Reinforcement

Material used for reinforcement shall preferably be the same as that of the vessel wall. If the material of the nozzle wall or reinforcement has a lower design stress value S than that for the vessel material, the amount of area provided by the nozzle wall or reinforcement in satisfying the requirements of ND-3332 shall be taken as the actual area provided multiplied by the ratio of the nozzle or reinforcement material design stress value to the vessel material design stress value. No reduction in the reinforcing required may be taken for the increased strength of reinforcing material and weld metal having higher design stress values than that of the material of the vessel wall. Deposited weld metal outside of either the

vessel wall or any reinforcing pad used as reinforcement shall be credited with an allowable stress value equivalent to the weaker of the materials connected by the weld. Vessel-to-nozzle or pad-to-nozzle attachment weld metal within the vessel wall or within the pad may be credited with a stress value equal to that of the vessel wall or pad, respectively.

ND-3336.1 Strength of Weld.

On each side of the plane defined in ND-3334, the strength of the attachment joining the vessel wall and reinforcement or any two parts of the attached reinforcement shall be at least equal to the lesser of (a) or (b) below:

(a) the strength in tension of the cross section of the element of reinforcement being considered;

(b) the strength in tension of the area defined in ND-3332 less the strength in tension of the reinforcing area which is integral in the vessel wall.

ND-3336.2 Strength of Attachment.

The strength of the attachment joint shall be considered for its entire length on each side of the plane of the area of reinforcement defined in ND-3334. For obround openings, consideration shall also be given to the strength of the attachment joint on one side of the plane transverse to the parallel sides of the opening which passes through the center of the semicircular end of the opening.

ND-3350 DESIGN OF WELDED CONSTRUCTION

ND-3351 Welded Joint Categories

The term *Category* defines the location of a joint in a vessel but not the type of joint. The categories are for use in specifying special requirements regarding joint type and method of examination for certain welded joints. Since these special requirements, which are based on service, material, and thickness, do not apply to every welded joint, only those joints to which special requirements apply are included in the categories. The special requirements apply to joints of a given category only when specifically stated. The joints included in each category are designated as joints of Categories A, B, C, and D. Figure ND-3351-1 illustrates typical joint locations included in each category.

ND-3351.1 Category A.

Category A comprises longitudinal welded joints within the main shell, communicating chambers,¹² transitions in diameter, or nozzles; any welded joint within a sphere, within a formed or flat head, or within the side plates¹³ of a flat sided vessel; circumferential welded joints connecting hemispherical heads to main shells, to transitions in diameters, to nozzles, or to communicating chambers.

ND-3351.2 Category B.

Category B comprises circumferential welded joints within the main shell, communicating chambers,¹² nozzles, or transitions in diameter, including joints between the transition and a cylinder at either the large or small end; circumferential welded joints connecting formed heads other than hemispherical to main shells, to transitions in diameter, to nozzles, or to communicating chambers.

¹² Communicating chambers are defined as appurtenances to the vessel which intersect the shell or head of a vessel and form an integral part of the pressure retaining closure, e.g., sumps.

¹³ Side plates of a flat sided vessel are defined as any of the flat plates forming an integral part of the pressure retaining enclosure.

ND-3351.3 Category C.

Category C comprises welded joints connecting flanges, Van Stone laps, tube sheets, or flat heads to main shell, to formed heads, to transitions in diameter, to nozzles or to communicating

chambers;¹² any welded joint connecting one side plate¹³ to another side plate of a flat sided vessel.

FIG. ND-3351-1 WELDED JOINT LOCATIONS TYPICAL OF CATEGORIES A, B, C, AND D

FIG. ND-3351-1 WELDED JOINT LOCATIONS TYPICAL OF CATEGORIES A, B, C AND D

ND-3351.4 Category D.

Category D comprises welded joints connecting communicating chambers or nozzles to main shells, to spheres, to transitions in diameter, to heads or to flat sided vessels and those joints connecting nozzles to communicating chambers. For nozzles at the small end of a transition in diameter, see Category B.

ND-3352 Permissible Types of Welded Joints

The design of the vessel shall meet the requirements for each category of joint. Butt joints are full penetration joints between plates or other elements that lie approximately in the same plane. Category B angle joints between plates or other elements that have an offset angle α not exceeding 30 deg are considered as meeting the requirements for butt joints. Figure ND-3352-1 shows typical butt welds for each category joint.

[98]

ND-3352.1 Joints of Category A.

All welded joints of Category A as defined in ND-3351 shall meet the fabrication requirements of ND-4241 and shall be capable of being examined in accordance with ND-5210. The joint efficiency E shall not exceed that given in (a) through (e) below.

(a) When the butt weld is fully radiographed in accordance with ND-5211.1(a), E used in the design calculations for determining the thickness of the part shall not exceed 1.00 for Type 1 butt welds and 0.90 for Type 2 butt welds.

(b) When the vessel section or part is spot radiographed in accordance with ND-5211.1(b), the value of E used in the design calculations for determining the thickness of the part shall not exceed 0.85 for Type 1 butt welds and 0.80 for Type 2 butt welds.

(c) When the vessel section or part is neither fully radiographed nor spot radiographically examined as allowed by ND-5211.1(c), the value of E used in the design calculations for determining the thickness of the part shall not exceed 0.70 for Type 1; 0.65 for Type 2; 0.60 for Type 3; 0.55 for Type 4; 0.50 for Type 5; and 0.45 for Type 6 welds. In other cases, the allowable stresses used in the design calculations shall not exceed 80% of the listed values in the stress tables. This 80% factor does not apply to allowable stresses for S_a , S_b , S_p and S_n used in flange design and defined in XI-3130 or for calculating the thickness of braced and stayed surfaces for Eqs. (19) and (20) of ND-3329.1(a). The value of E for

vessels designed for external pressure only may be taken as 1.00.

(d) For vessels constructed of unalloyed titanium, all weld joints of Category A shall be Type 1 or Type 2.

(e) For vessels constructed of SB-443, SB-444, and SB-446, all weld joints of Category A shall be Type 1 or Type 2.
[98]

ND-3352.2 Joints of Category B.

All welded joints of Category B as defined in ND-3351 shall meet the fabrication requirements of ND-4242 and shall be capable of being examined in accordance with ND-5220. The joint efficiency E shall not exceed that given in (a) through (e) below.

(a) When the butt weld is fully radiographed, the design provisions of ND-3352.1(a) shall apply.

Page 93

FIG. ND-3352-1 TYPICAL BUTT JOINTS

FIG. ND-3352-1 TYPICAL BUTT JOINTS

(b) When the butt weld is partially radiographed as allowed by ND-5221(b) or when the vessel section or part is spot radiographed in accordance with ND-5221(c), the value of E used in the longitudinal stress calculations shall be as stated in ND-3352.1(b). When seamless vessel sections or heads with Category B butt weld joints are spot radiographed, the allowable stresses used in the design calculations for determining the thickness of the vessel section or part shall not exceed 85% of the values listed in the stress tables. This factor does not apply to allowable stresses for S_a , S_b , S_p and S_n used in flange design and defined in XI-3130 or for calculating the thickness of braced or stayed surfaces for Eqs. (19)

and (20) of ND-3329.1(a).

(c) When the vessel section or part is neither fully radiographed, partially radiographed, nor spot radiographed, the design provisions of ND-3352.1(c) apply.

(d) For vessels constructed of unalloyed titanium, all weld joints of Category B shall be Type 1 or Type 2.

(e) For vessels constructed of SB-443, SB-444, and SB-446, all weld joints of Category B shall be Type 1 or Type 2.

ND-3352.3 Joints of Category C.

All welded joints of Category C as defined in ND-3351 shall meet the fabrication requirements of ND-4243 and shall be capable of being examined in accordance with ND-5230. The design for attaching flanged heads shall meet the requirements of ND-3358. The design requirements of Category C butt welds are given in (a) through (e) below.

Page 94

(a) When a Category C butt weld is fully radiographed, the design provisions of ND-3352.1(a) shall apply.

(b) When a Category C butt weld is spot radiographed, the design provisions of ND-3352.2(b) shall apply.

(c) When a Category C butt weld is not radiographed, the design provisions of ND-3352.1(c) shall apply.

(d) When a Category C corner joint is used, the design requirements of ND-3325 and the dimensional requirements of Fig. ND-4243-1 specified in ND-3358.3 shall be met.

(e) For vessels constructed of SB-443, SB-444, and SB-446, all weld joints of Category C shall be Type 1 or Type 2 when the Design Temperature is 1000°F or higher.

ND-3352.4 Joints of Category D.

All welded joints of Category D as defined in ND-3351 shall be in accordance with the requirements of ND-3359 and one of (a) through (h) below.

(a) *Butt Welded Attachments.* Nozzles shall meet the fabrication requirements of ND-4244(a) and shall be capable of being examined in accordance with ND-5241. The minimum dimensions and geometrical requirements of Fig. ND-4244(a)-1 shall be met, where:

t	= nominal thickness of part penetrated, in.
t_n	= nominal thickness of penetrating part, in.
r_1	= $\frac{1}{4}t$ or $\frac{3}{4}$ in. (19 mm), whichever is less
r_2	= $\frac{1}{4}$ in. (6 mm) minimum

(b) *Full Penetration Corner Welded Attachments.* Nozzles shall meet the fabrication requirements of ND-4244(b) and shall be capable of being examined as required in ND-5241. Inserted-type nozzles having added reinforcement in the form of a separate reinforcing plate shall be attached by welds at the outer edge of the reinforcement plate and at the nozzle periphery. The weld at the outer edge of the reinforcement shall be a fillet weld with a minimum throat dimension of $\frac{1}{2}t_{\min}$. The minimum dimensions of Fig. ND-4244(b)-1 shall be met, where:

t	= nominal thickness of part penetrated, in.
t_n	= nominal thickness of penetrating part, in.
t_c	= $0.7t_n$ or $\frac{1}{4}$ in. (6 mm), whichever is less
r_1	= $\frac{1}{4}t$ or $\frac{3}{4}$ in. (19 mm), whichever is less
r_2	= $\frac{1}{4}$ in. (6 mm) minimum
t_e	= thickness of reinforcing element, in.

$t_{\min}$	= the lesser of $\frac{3}{4}$ in. (19 mm) or the thickness of the
$t_{\min}$	= the lesser of $\frac{3}{4}$ in. (19 mm) or the thickness of the thinner of the parts joined

(c) *Use of Deposited Weld Metal for Openings and Attachments*

(1) Nozzles shall meet the requirements of ND-4244(c) and shall be capable of being examined in accordance with ND-5241.

(2) When the deposited weld metal is used as reinforcement, the coefficients of thermal expansion of the base metal, the weld metal, and the nozzle shall not differ by more than 15% of the lowest coefficient involved.

(3) The minimum dimensions of Fig. ND-4244(c)-1 shall be met, where:

t	= nominal thickness of part penetrated, in.
t_n	= nominal thickness of penetrating part, in.
t_c	= $0.7t_n$ or $\frac{1}{4}$ in. (6 mm), whichever is less
r_1	= $\frac{1}{4}t$ or $\frac{3}{4}$ in. (19 mm), whichever is less

(4) The corners of the end of each nozzle extending less than $\sqrt{dt_n}$ beyond the inner surface of the part penetrated shall be rounded to a radius of one-half the thickness t_n of the nozzle or $\frac{3}{4}$ in. (19 mm), whichever is less.

(d) *Attachment of Nozzles Using Partial Penetration Welds*

(1) Partial penetration welds shall meet the requirements of ND-4244(d). Typical details are shown in Fig. ND-4244(d)-1. For inserted nozzles without reinforcing elements, two partial penetration welds or a combination of fillet, single bevel, and single J-welds may be used. Inserted-type nozzles having added reinforcement in the form of a separate reinforcing plate shall be attached by welds at the outer edge of the reinforcement plate and at the nozzle periphery. The weld at the outer edge of the reinforcement shall be a fillet weld with a minimum throat dimension of $\frac{1}{2}t_{\min}$. The welds attaching the nozzles to the vessel wall and to the reinforcement shall consist of one of the combinations given in (a) through (c) below.

(a) A single bevel or single J-weld in the shell plate and a single bevel or single J-weld in each reinforcement plate. The dimension t_w of each weld shall be not less than $0.7t_{\min}$ [ND-4244(d)-1].

(b) A full penetration groove weld in the shell plate and a fillet, single bevel, or single J-weld with a weld dimension t_w not less than $0.7t_{\min}$ in each reinforcement plate [Fig. ND-4244(d)-1 sketch (f)].

(c) A full penetration groove weld in each reinforcement plate and a fillet, single bevel, or single J-weld with a weld dimension t_w not less than $0.7t_{\min}$ in the shell plate [Fig. ND-4244(d)-1 sketch (e)]. These welds shall be capable of being examined in accordance with the requirements of ND-5241.

(2) The minimum dimensions of Fig. ND-4244(d)-1 shall be met, where:

$t_1 + t_2$	= $\frac{1}{4}t_{\min}$
-------------	-------------------------

Page 95

t_1 or t_2	= not less than the lesser of $\frac{1}{4}$ in. or $0.7t_{\min}$
$t_{\min}$	= the lesser of $\frac{3}{4}$ in. or the thickness of the thinner of the parts joined
t_e	= thickness of reinforcement element, in.
t	= nominal thickness of part penetrated, in.
t_n	= nominal thickness of penetrating part, in.

$$\begin{aligned}
 t_c &= 0.7t_n \text{ or } 1/4 \text{ in., whichever is less} \\
 c &= 1/2 t_{\min} \\
 t_w &= 0.7t_n \text{ except } t_w = 0.7t_{\min} \text{ for sketch (e)}
 \end{aligned}$$

(e) *Attachment of Fittings With Internal Threads.*¹⁴ The attachment of internally threaded fittings shall meet the requirements of (1) through (3) below.

(1) Except as provided for in (2) and (3) below, the provisions of ND-4244(e) shall be met. The minimum weld dimensions shall be as shown in Fig. ND-4244(e)-1 where:

$$\begin{aligned}
 t_{\min} &= \text{lesser of } 3/4 \text{ in. or the thickness of the parts joined} \\
 t_c &= 1/4 \text{ in., minimum}
 \end{aligned}$$

Sketches (a) and (b):

$$t_1 + t_2 = 1/4 t_{\min}$$

Sketch (c):

$$t_w = \text{thickness of Sch. 160 pipe (ANSI-B36.10)}$$

$$t_1 + t_2 \text{ not less than the lesser of } 1/4 \text{ in. or } 0.7t_{\min}$$

Sketch (d):

$$t_w = 0.7t_{\min}$$

(2) Fittings shown in Fig. ND-4244(e)-1 sketches (a-2), (b-2), (c-2), and (d) not exceeding NPS 3 may be attached by welds that are exempt from size requirements other than those specified in ND-3359.

(3)(a) When internally threaded fittings and bolting pads not exceeding NPS 3 (DN 80) are attached to vessels having a wall thickness not greater than $3/8$ in. (10 mm) by a fillet weld deposited from the outside only, the welds shall comply with the dimensions shown in Fig. ND-4244(e)-2. These openings do not require reinforcement other than that inherent in the construction as permitted in ND-3332.1.

(b) If the opening exceeds $5/8$ in. (136 mm) in any direction or is greater than one-half the vessel diameter, the part of the vessel affected shall be subjected to a proof test as required in ND-6900 or the opening shall be reinforced in accordance with ND-3332 with the nozzle or other connections attached, using a suitable detail in Fig. ND-4244(e)-1.

¹⁴ Written for fittings with internal threads but also applicable to externally threaded and socket or butt welded fittings.

(f) *Attachment of Tubed Connections.* Nozzles or tubes recessed into thick walled vessels or headers, welded from only one side, shall have a welding groove in the vessel wall not deeper than t_n on the longitudinal axis of the opening. A recess $1/16$ in. (1.6 mm) deep shall be provided at the bottom of the groove in which to center the nozzle. The dimension t_w of the attachment weld shall not be less than t_n nor less than $1/4$ in. (6 mm). The minimum dimension for t_c shall be $1/4$ in. (6 mm) [Fig. ND-4244(f)-1 sketches (a) and (b)].

(g) *Nozzles With Integral Reinforcing.* Nozzles and other connections having integral reinforcement in the form of extended nozzles or saddle type pads shall have the throat dimension of the outer weld not less than $1/2 t_{\min}$ [Fig. ND-4244(g)-1]. The dimension t_w of the inner weld shall be not less than $0.7t_{\min}$, where:

$$\begin{aligned}
 t_n &= \text{nominal thickness of neck, in.} \\
 t &= \text{nominal thickness of shell, in.} \\
 t_e &= \text{thickness of reinforcement element, in.} \\
 t_c &= 0.7t_n \text{ or } 1/4 \text{ in. (6 mm), whichever is less}
 \end{aligned}$$

c	$= \frac{1}{2}t_{\min}$
$t_{\min}$	$= \text{lesser of } \frac{3}{4} \text{ in. (19 mm) or the thickness of the thinner of the parts joined}$
t_w	$= 0.7t_{\min}$

(h) For vessels constructed of SB-443, SB-444, and SB-446, all weld joints of Category D shall be Type 1 or Type 2 when the Design Temperature is 1000°F (538°C) or higher.

ND-3354 Structural Attachment Welds

Welds for structural attachments shall meet the requirements of ND-4430.

ND-3355 Welding Grooves

The dimensions and shape of the edges to be joined shall be such as to permit complete fusion and complete joint penetration. Qualification of the welding procedure, as required in ND-4000, is acceptable as proof that the welding groove is satisfactory.

ND-3356 Fillet Welds, Lap Joints, and Plug Welds

ND-3356.1 Fillet Welds

(a) Fillet welds may be used as strength welds within the limitations given in ND-3352 and Fig. ND-4427-1. Particular care shall be taken in the layout of joints in which fillet welds are to be used in order to assure complete fusion at the root of the fillet.

(b) Corner or tee joints may be made with fillet welds provided the plates are properly supported independently

Page 96

of such welds, except that independent supports are not required for joints used for lugs or clips.

(c) The allowable load on fillet welds shall equal the product of the weld area based on minimum leg dimensions, the allowable stress value in tension of the material being welded, and a joint efficiency of 0.55.

[98]

ND-3356.2 Lap Joints.

For lap joints, the surface overlap shall be not less than four times the thickness of the inner plate except as otherwise provided for heads in ND-3358 and for tanks in ND-4246.

[98]

ND-3356.3 Plug Welds

(a) Plug welds may be used in lap joints, in reinforcements around openings, and in structural attachments. Plug welds shall be properly spaced to carry no more than 30% of the total load to be transmitted.

(b) Plug weld holes shall have a diameter not less than $t + \frac{1}{4}$ in. and not more than $2t + \frac{1}{4}$ in., where t is the thickness in inches of the plate or attached part in which the hole is made.

(c) Plug weld holes shall be completely filled with weld metal when the thickness of the plate or attached part in which the weld is made is $\frac{5}{16}$ in. (8 mm) or less; for thicker plates or attached parts, the holes shall be filled to a depth of at least half the plate thickness or $\frac{5}{16}$ of the hole diameter, whichever is larger, but in no case less than $\frac{5}{16}$ in. (8 mm).

(d) The allowable load on a plug weld in either shear or tension shall be computed by the following equation:

$$P = 0.63S(d - \frac{1}{4})^2$$

where

P	= total allowable load on the plug weld, lb
d	= the bottom diameter of the hole in which the weld is made, in.
S	= maximum allowable stress, psi (Tables 1A and 1B, Section II, Part D, Subpart 1)

ND-3357 Welded Joints Subject to Bending Stresses

Except where specific details are permitted in other paragraphs, fillet welds shall be added where necessary to reduce stress concentration. Corner joints, with fillet welds only, shall not be used unless the plates forming the corner are properly supported independently of such welds [ND-3356.1(b)].

ND-3358 Design Requirements for Head Attachments

ND-3358.1 Skirt Length of Formed Heads

(a) Ellipsoidal and other types of formed heads, concave or convex to the pressure, shall have a skirt length not less than that shown in Fig. ND-3358.1(a)-1. Heads that are fitted inside or over a shell shall have a driving fit before welding.

(b) A tapered transition having a length not less than three times the offset between the adjacent surfaces of abutting sections as shown in Fig. ND-3358.1(a)-1 shall be provided at joints between formed heads and shells that differ in thickness by more than one-fourth the thickness of the thinner section or by more than $\frac{1}{8}$ in. (3.2 mm), whichever is less. When a taper is required on any formed head thicker than the shell and intended for butt welded attachment [Fig. ND-3358.1(a)-1], the skirt shall be long enough so that the required length of taper does not extend beyond the tangent line.

(c) All formed heads concave to pressure and intended for butt welded attachment need not have an integral skirt when the thickness of the head is equal to or less than the thickness of the shell. When a skirt is provided, its thickness shall be at least that required for a seamless shell of the same diameter.

ND-3358.2 Unstayed Flat Heads Welded to Shells.

The requirements for the attachment of unstayed flat heads welded to shells are given in ND-3325, ND-3358.3, and ND-3358.6.

ND-3358.3 Head Attachments Using Corner Joints.

When shells, heads, or other pressure parts are welded to a forged or rolled plate to form a corner joint, as in Fig. ND-4243-1, the joint shall meet the requirements of (a) through (f) below.

(a) On the cross section through the welded joint, the line of fusion between the weld metal and the forged or rolled plate being attached shall be projected on planes both parallel to and perpendicular to the surface of the plate being attached, in order to determine the dimensions a and b , respectively.

(b) For flange rings of bolted flanged connections and for flat heads and unsupported tube sheets with a projection having holes for a bolted connection, the sum of a and b shall be not less than three times the nominal wall thickness of the abutting pressure part.

(c) For supported tube sheets with a projection having holes for a bolted connection, the sum of a and b shall not be less than two times the nominal wall thickness of the abutting pressure part. A supported tubesheet is defined as one in which not less than 80%

of the pressure load on the tubesheet is carried by tubes, stays, or braces.

GENERAL NOTES [sketches (a) and (b)]:

- (a) Length of required taper ℓ may include the width of the weld.
- (b) In all cases, the projected length of taper ℓ shall be not less than $3y$.
- (c) The shell plate center line may be on either side of the head plate center line.

GENERAL NOTES [sketches (c) and (d)]:

- (a) In all cases ℓ shall be not less than 3 times y when t_h exceeds $1.25 t_s$; minimum length of skirt is $3 t_h$, but need not exceed 1-1/2 in. except when necessary to provide required length of taper.
- (b) When t_h is equal to or less than $1.25 t_s$, length of skirt shall be sufficient for any required taper.
- (c) Length of required taper ℓ may include the width of the weld.
- (d) The shell plate center line may be on either side of the head plate center line.

FIG. ND-3358.1(a)-1 HEADS ATTACHED TO SHELLS

FIG. ND-3358.1(a)-1 HEADS ATTACHED TO SHELLS

(d) For other components, the sum of a and b shall be not less than two times the nominal wall thickness of the abutting pressure part. Examples of such components are flat heads and supported and unsupported tubesheets without a projection having holes for a bolted connection and the side plates of a rectangular vessel.

(e) Other dimensions at the joint shall be in accordance with details as shown in Fig. ND-4243-1:

(1) sketch (a):

$$a + b \text{ not less than } 2t_s, (b = 0)$$

$$t_w \text{ not less than } t_s$$

$$t_s = \text{actual thickness of shell, in.}$$

(2) sketch (b):

$$a + b \text{ not less than } 2t_s$$

$$t_w \text{ not less than } t_s$$

$$t_p \text{ not less than } t_s$$

$$t_s = \text{actual thickness of shell, in.}$$

(3) sketch (c):

$$a + b \text{ not less than } 2t_s$$

$$a \text{ not less than } t_s$$

$$t_p \text{ not less than } t_s$$

$$t_s = \text{actual thickness of shell, in.}$$

(4) sketch (d):

$$a + b \text{ not less than } 2t_s$$

$$a \text{ not less than } t_s$$

$$t_p \text{ not less than } t_s$$

$$t_s = \text{actual thickness of shell, in.}$$

(5) sketch (e):

$$a + b \text{ not less than } 2t_s, (b = 0)$$

$$t_s = \text{actual thickness of shell, in.}$$

(6) sketch (f):

$$a + b \text{ not less than } 2t_s$$

$$t_s = \text{actual thickness of shell, in.}$$

(7) sketch (g):

$$a + b \text{ not less than } 2t_s$$

$$a_1 \text{ not less than } 0.5a_2 \text{ nor greater than } 2a_2$$

$$a_1 + a_2 = a$$

$$t_s = \text{actual thickness of shell, in.}$$

(8) sketches (h) through (j):

$$t_r = \text{required thickness of shell, in.}$$

$$c = 0.7t_s$$

$t_w = 2t_r$ but not less than $1.25t_s$

t_w need not be greater than t

t_s = actual thickness of shell, in.

(9) sketches (k) through (o):

(a) for supported tubesheets:

$a + b$ not less than $2t_s$

c not less than $0.7t_s$ or $1.4t_r$, whichever is less

a_1 not less than $0.5a_2$

t_s = actual thickness of shell, in.

(b) for flange rings, flat heads, and unsupported tubesheets:

$a + b$ not less than $3t_s$

c not less than t_s or $2t_r$, whichever is less

a_1 not less than $0.5a_2$

t_s = actual thickness of shell, in.

(10) sketch (p):

a not less than $3t_r$ ($b = 0$)

c not less than t_n or t_D^{15} whichever is less

(11) sketch (q):

$a + b$ not less than $3t_n$

c not less than t_n or t_D^{15} whichever is less

(f) Joint details that have a dimension through the joint less than the thickness of the shell, head, or other pressure part, or that provide eccentric attachment, are not permissible [Fig. ND-4243-1 sketches (r), (s), and (t)].

ND-3358.4 Intermediate Heads

(a) Intermediate heads of the type shown in Fig. ND-4245-1 sketch (f), without limit to thickness, may be used for all types of vessels provided that the outside diameter of the head skirt is a close fit inside the overlapping ends of the adjacent length of cylinder.

(b) The butt weld and fillet weld shall be designed to take shear based on 1.5 times the maximum differential pressure that can exist. The allowable stress value for the butt weld shall be 70% of the stress value for the vessel material, and the allowable value for the fillet weld shall be 55% of the stress value for the vessel material. The area of the fillet weld is the minimum leg dimension times the length of the weld. The area of the butt weld in shear is the smaller of the width at the root of the weld or the thickness of the vessel shell to which it is attached times the length of the weld.

(c) This construction may also be used for end closures when the thickness of the shell section of the vessel does not exceed $\frac{5}{8}$ in. (16 mm).

ND-3358.5 Heads Concave to Pressure.

Heads concave to pressure may be attached to shells using a butt weld with one plate offset as shown in Fig. ND-4245-1 sketch (k). The offset shall be smooth and symmetrical, and shall not be machined or otherwise reduced in thickness. There shall be a uniform force fit with the mating section at the root of the weld.

ND-3358.6 Flat Heads and Tubesheets With Hubs.

Hubs for butt welding to the adjacent shell, head, or other pressure part, as in Fig. ND-4243.1-1, shall not be machined from rolled plate. The component having

Page 99

the hub shall be forged in such a manner as to provide in the hub the full minimum tensile strength and elongation specified for the material, in a direction parallel to the axis of the vessel. Proof of this shall be furnished by a tension test specimen (subsize if necessary) taken in this direction and as close to the hub as is practical.

In Fig. ND-4243.1-1, the minimum dimensions are as follows:

(a) sketch (a):

r not less than $1.5t_s$

(b) sketch (b):

r not less than $1.5t_s$

e not less than t_s

(c) sketch (c):

h not less than $1.5t_s$

(d) sketch (d):

t_f not less than $2t_s$

r not less than $3t_f$

(e) sketch (e):

t_f not less than $2t_s$

r not less than $3t_f$

e not less than t_f

ND-3359 Design Requirements for Nozzle Attachment Welds

In addition to the requirements of ND-3352.4, the minimum design requirements for nozzle attachment welds are given in (a) and (b) below.

(a) *Required Weld Strength.* Sufficient welding shall be provided on either side of the line through the center of the opening parallel to the longitudinal axis of the shell to develop the strength of the reinforcing parts as required in ND-3336, through shear or tension in the weld, whichever is applicable. The strength of groove welds shall be based on the area subjected to shear or to tension. The strength of fillet welds shall be based on the area subjected to shear, computed on the minimum leg dimension. The inside diameter of a fillet weld shall be used in figuring its length. Calculations are not required when full penetration welds are used.

(b) *Allowable Stress Values for Welds.* The allowable stress values for groove and fillet welds and for shear in nozzles, in percentage of stress values for the vessel material, are as follows:

Nozzle wall shear	70%
Groove weld tension	74%
Groove weld shear	60%
Fillet weld shear	49%

ND-3360 SPECIAL VESSEL REQUIREMENTS

ND-3361 Tapered Transitions, Staggered Welds, and Threaded Connections

ND-3361.1 Tapered Transitions.

A tapered transition having a length not less than three times the offset between the adjacent surfaces of abutting sections (Fig. ND-3361.1-1) shall be provided at joints between sections that differ in thickness by more than one-fourth of the thickness of the thinner section or by more than $\frac{1}{8}$ in. (3.2 mm), whichever is less. The transition may be formed by any process that will provide a uniform taper. The weld may be in the tapered section or adjacent to it. This paragraph also applies when there is a reduction in thickness within a spherical shell or cylindrical shell course and to a taper at a Category A joint within a formed head. Provisions for tapers at circumferential butt welded joints connecting formed heads to main shells are contained in ND-3358.1(b).

ND-3361.2 Staggered Welds.

Except when radiographed 4 in. each side of each welded intersection, vessels made up of two or more courses shall have the centers of the welded longitudinal joints of adjacent courses staggered or separated by a distance of at least five times the thickness of the thicker plate.

ND-3361.3 Threaded Connections

(a) Pipes, tubes, and other threaded connections that conform to ANSI B2.1, Pipe Threads, may be screwed into a threaded hole in a vessel wall provided the pipe engages the minimum number of threads specified in Table ND-3361.3(a)-1 after allowance has been made for curvature of the vessel wall. A built-up pad or a properly attached plate or fitting may be used to provide the metal thickness and number of threads required in Table ND-3361.3(a)-1, or to furnish reinforcement when required.

(b) Threaded connections larger than NPS 3 (DN 80) shall not be used when the maximum allowable pressure exceeds 125 psi (861 kPa), except that this NPS 3 (DN 80) restriction does not apply to plug closures used for inspection openings, end closures, or similar purposes.

ND-3362 Bolted Flange and Studded Connections

(a) It is recommended that the dimensional requirements of bolted flange connections to external piping conform to ANSI Standard B16.5, Steel Pipe Flanges and Flanged Fittings; ANSI B16.24, Brass or Bronze

Page 100

and Flanged Fittings 150 and 300 lb; MSS SP-42, 150 lb Corrosion Resistant Cast Flanged Valves; or to API Standard 605, Large Diameter Carbon Steel Flanges. Such flanges and flanged fittings may be used for the pressure-temperature ratings given in the appropriate standard. Flanges and flanged fittings to other standards are acceptable provided they have been designed in accordance with the rules of Appendix XI for the vessel design loadings and are used within the pressure-temperature ratings so determined.

FIG. ND-3361.1-1 BUTT WELDING OF PLATES OF UNEQUAL THICKNESSES

FIG. ND-3361.1-1 BUTT WELDING OF PLATES OF UNEQUAL THICKNESSES

TABLE ND-3361.3(a)-1
MINIMUM NUMBER OF PIPE THREADS FOR CONNECTIONS

Size of pipe connections, in.	$\frac{1}{2}, \frac{3}{4}$	1, $1\frac{1}{4}$, $1\frac{1}{2}$	2	$2\frac{1}{2}$, 3	4-6	8	10	12
Threads engaged	6	7	8	8	10	12	13	14
Min. plate thickness required, in.	0.43	0.61	0.70	1.0	1.25	1.5	1.62	1.75

TABLE ND-3361.3(a)-1 MINIMUM NUMBER OF PIPE THREADS FOR CONNECTIONS

(b) Where tapped holes are provided for studs, the threads shall be full and clean and shall engage the stud for a length not less than the larger of d_s or:

$$0.75d_s \times \frac{\text{Maximum allowable stress value of stud material at Design Temperature}}{\text{Maximum allowable stress value of tapped material at Design Temperature}}$$

in which d_s is the diameter of the stud. The thread engagement need not exceed $1\frac{1}{2}d_s$.

ND-3363 Access or Inspection Openings¹⁶

ND-3363.1 General Requirements

(a) All vessels for use with compressed air, except as otherwise permitted, and those subject to internal corrosion or having parts subject to erosion or mechanical abrasion (ND-3121), shall be provided with suitable manhole, handhole, or other inspection openings for examination and cleaning.

16 All dimensions given, for size of vessel on which inspection openings are required, are nominal.

(b) Vessels over 12 in. (305 mm) inside diameter under air pressure which also contain other substances which will prevent corrosion need not have openings for inspection only, providing the vessel contains suitable

Page 101

openings through which inspection can be made conveniently and providing such openings are equivalent in size and number to the requirements for inspection openings in ND-3363.3.

(c) Compressed air is not intended to include air which has had moisture removed to the degree that it has an atmospheric dew point of -50°F (+46°C) or less. The Certificate Holder's Data Report shall include a statement for "noncorrosive service" when inspection openings are not provided.

(d) When provided with telltale holes complying with the provisions of (e) below, inspection openings as required in ND-3363 may be omitted in vessels subject only to corrosion. This provision does not apply to vessels for compressed air.

(e) Telltale holes may be used to provide some positive indication when the thickness has been reduced to a dangerous degree. When telltale holes are provided they shall be at least $\frac{3}{16}$ in. (4.8 mm) in diameter and have a depth not less than 80% of the thickness required for a seamless shell of like dimensions. These holes shall be provided in the surface opposite to that where deterioration is expected.

ND-3363.2 Requirements for Vessels 12 in. (305 mm) Inside Diameter and Smaller.

For vessels 12 in. (305 mm) or less inside diameter, openings for inspection only may be omitted if there are at least two removable pipe connections not less than NPS $\frac{3}{4}$ (DN 20).

ND-3363.3 Requirements for Vessels Over 12 in. (305 mm), but Not Over 16 in. (406 mm) Inside Diameter.

Vessels over 12 in. (305 mm), but not over 16 in. (406 mm) inside diameter, that are to be installed so that they may be

disconnected from an assembly to permit inspection, need not be provided with openings for inspection only, if there are at least two removable pipe connections not less than NPS 1½ (DN 40).

ND-3363.4 Equipment of Vessels Requiring Access or Inspection Openings.

Vessels that require access or inspection openings shall be equipped as required in (a) through (f) below.

(a) All vessels less than 18 in. (457 mm) and over 12 in. (305 mm) inside diameter shall have at least two handholes or two plugged, threaded inspection openings of not less than NPS 1½ (DN 40).

(b) All vessels 18 in. to 36 in. (457 mm to 914 mm), inclusive, inside diameter shall have a manhole or at least two handholes or two threaded pipe plug inspection openings of not less than NPS 2 (DN 50).

(c) All vessels over 36 in. (914 mm) inside diameter shall have a manhole, except that those whose shape or use makes one impracticable shall have at least two handholes 4 in. × 6 in. (102 mm × 152 mm) or two equal openings of equivalent areas.

(d) When handholes or pipe plug openings are permitted for inspection openings in place of a manhole, one handhole or one pipe plug opening shall be in each head or in the shell near each head.

(e) Openings with removable heads or cover plates intended for other purposes may be used in place of the required inspection openings provided they are equal at least to the size of the required inspection openings.

(f) A single opening with removable head or cover plate may be used in place of all the smaller inspection openings provided it is of such size and location as to afford at least an equal view of the interior.

ND-3363.5 Size and Type of Access and Inspection Openings.

When inspection or access openings are required, they shall comply at least with the requirements of (a) and (b) below.

(a) An elliptical or obround manhole shall be not less than 11 in. × 15 in. (280 mm × 381 mm) or 10 in. × 16 in. (254 mm × 406 mm). A circular manhole shall be not less than 15 in. (381 mm) inside diameter.

(b) A handhole opening shall be not less than 2 in. × 3 in. (51 mm × 76 mm), but should be as large as is consistent with the size of the vessel and the location of the opening.

ND-3363.6 Design of Access and Inspection Openings in Shells and Heads.

All access and inspection openings in a shell or unstayed head shall be designed in accordance with the rules for openings.

ND-3363.7 Minimum Gasket Bearing Width for Manhole Cover Plates.

Manholes of the type in which the internal pressure forces the cover plate against a flat gasket shall have a minimum gasket bearing width of 1½ in. (38 mm).

ND-3363.8 Threaded Openings.

When a threaded opening is to be used for inspection or cleaning purposes, the closing plug or cap shall be of a material suitable for the pressure and no material shall be used at a temperature exceeding the maximum temperature allowed for that material. The thread shall be a standard taper pipe thread, except that a straight thread of equal strength may be used if other sealing means to prevent leakage are provided.

ND-3364 Attachments

Attachments used to transmit support loads shall meet the requirements of ND-3135.

Page 102

ND-3365 Supports

All vessels shall be so supported and the supporting members shall be arranged or attached to the vessel wall in such a way as to withstand the maximum imposed loadings (ND-3111 and Subsection NF).

ND-3366 Bellows Expansion Joints

Expansion joints of the bellows type may be used to provide flexibility for vessels. Expansion joints in piping portions of vessels shall meet the requirements of ND-3649. The design, material, fabrication, examination, and testing of expansion joints which are constructed as a part or appurtenance of a vessel shall conform with the requirements of (a) through (i) below.

(a) Bellows may be used to absorb axial movement, lateral deflection, angular rotation, or any combination of these movements. They are not normally designed for absorbing torsion. The layout, anchorage, guiding, and support shall be such as to avoid the imposition of motions or forces on the bellows other than those for which they have been designed.

(b) In all systems containing bellows, the hydrostatic end force caused by either or both pressure or the bellows spring force shall be resisted by rigid anchors, cross connections of the expansion joint ends, or other means.

(c) The expansion joint shall be installed in such locations as to be accessible for scheduled inspection, where applicable.

(d) The joints shall be provided with bars or other suitable members for maintaining the proper face-to-face dimension during shipment and installation. Bellows shall not be extended or compressed to make up deficiencies in length or offset to accommodate connecting parts which are not properly aligned unless such movements have been specified by the system designer or can be justified by the expansion joint manufacturer.

(e) The expansion joints shall be marked to show the direction of flow, if applicable, and shall be installed in accordance with this marking.

(f) Internal sleeves shall be provided for expansion joints over 6 in. in diameter when flow velocities exceed the following values:

(1) air, steam, and other gases - 25 ft/sec (9.6 m/s);

(2) water and other liquids - 10 ft/sec (3.0 m/s).

(g) Pressure retaining material in the expansion joint shall comply with the requirements of ND-2000.

(h) All welded joints shall comply with the requirements of ND-4400.

(i) Design of bellows-type expansion joints shall comply with the requirements of ND-3649.4.

ND-3400 PUMP DESIGN

ND-3410 GENERAL REQUIREMENTS FOR CENTRIFUGAL PUMPS

ND-3411 Scope

ND-3411.1 Applicability.

The rules of ND-3400 apply to (a) through (j) below:

(a) pump casings;

(b) pump inlets and outlets;

(c) pump covers;

(d) clamping rings;

(e) seal housings, seal glands, and packing glands;

(f) related bolting;

(g) pump internal heat exchanger piping;

(h) pump auxiliary nozzle connections up to the face of the first flange or circumferential joint in welded connections, excluding the connecting weld;

(i) piping identified with the pump and external to and forming part of the pressure retaining boundary, and supplied with the pump;

(j) external and internal integral attachments to the pressure retaining boundary;

Hydrostatic test of seal glands and packing glands is not required.

[98]

ND-3411.2Exemptions.

The rules of ND-3400 do not apply to (a) through (c) below:

(a) pump shafts and impellers; shafts may be designed in accordance with Appendix S

(b) nonstructural internals

(c) seal packages

[98]

ND-3412 Acceptability

The requirements for the design of pumps are given in (a) and (b) below.

(a) The design shall be such that the requirements of ND-3100 are satisfied.

(b) The rules of this Subarticle shall be met.

ND-3413 Design Specifications

Design and Service Conditions (NCA-2142) shall be stipulated in the Design Specification (NCA-3250). Loads from thermal expansion, dead weight, and applicable seismic forces from the connected piping shall be included in the Design Specification.

TABLE ND-3416-1
STRESS AND PRESSURE LIMITS FOR DESIGN AND
SERVICE LOADINGS

Service Limits	Stress Limits ¹	$P_{\max}$ ²
Design and Level A	$\sigma_m \leq S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.5S$	1.0
Level B	$\sigma_m \leq 1.1S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.65S$	1.1
Level C	$\sigma_m \leq 1.5S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.8S$	1.2
Level D	$\sigma_m \leq 2.0S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 2.4S$	1.5

NOTES:

- (1) These requirements for acceptability of pump design are not intended to assure the operability of the pump.
- (2) The maximum pressure shall not exceed the tabulated factors listed under $P_{\max}$ times the Design Pressure.

TABLE ND-3416-1 STRESS AND PRESSURE LIMITS FOR DESIGN AND SERVICE LOADINGS

ND-3414 Design and Service Loadings

The general design considerations, including definitions, of ND-3100 plus the requirements of ND-3320, ND-3330, ND-3361, and ND-3362, are applicable to pumps. The pump shall conform to the requirements of ND-3400. The stress limits listed in ND-3416 shall be used for the specified Design and Service Conditions. Classical bending and direct stress equations, where free body diagrams determine a simple stress distribution that is in equilibrium with the applied loads, or any design equations, which have been demonstrated to be satisfactory may be used.

ND-3415 Loads From Connected Piping

Loads imposed on pump inlets and outlets by connected piping shall be considered in the pump casing design.

17 Stress means the maximum normal stress.

ND-3416 Stress and Pressure Limits for Design and Service Loadings

Stress¹⁷ limits for Design and Service Loadings are specified in Table ND-3416-1. The symbols used in Table ND-3416-1 are defined as follows:

σ_m	= general membrane stress, ksi. This stress is equal to the average stress across the solid section under consideration. It excludes discontinuities and concentrations, and is produced only by pressure and other mechanical loads.
σ_L	= local membrane stress, ksi. This stress is the same as σ_m , except that it includes the effect of discontinuities.
σ_b	= bending stress, ksi. This stress is equal to the linear varying portion of the stress across the solid section under consideration. It excludes discontinuities and concentrations, and is produced only by pressure and other mechanical loads.
S	= allowable stress, ksi, given in Tables 1A and 1B, Section II, Part D, Subpart 1. The allowable stress shall correspond to the highest metal temperature of the section under consideration during the condition under consideration.

ND-3417 Earthquake Loadings

(a) The effects of earthquake shall be considered in the design of pumps, pump supports, and restraints. The stresses resulting from these earthquake effects shall be included with the stresses resulting from pressure or other applied loads.

(b) Where pumps are provided with drivers on extended supporting structures and these structures are essential to maintaining pressure integrity, an analysis shall be performed when required by the Design Specifications.

ND-3418 Corrosion

The requirements of ND-3121 apply.

ND-3419 Cladding

Cladding design dimensions used in the design of pumps shall be as required in ND-3122.

ND-3420 DEFINITIONS

ND-3421 Radially Split Casing

A radially split casing shall be interpreted as one in which the primary sealing joint is radially disposed around the shaft.

ND-3422 Axially Split Casing

An axially split casing shall be interpreted as one in which the primary sealing joint is axially disposed with respect to the shaft.

**FIG. ND-3423-1 TYPICAL SINGLE
VOLUTE CASING**

FIG. ND-3423-1 TYPICAL SINGLE VOLUTE CASING

ND-3423 Single and Double Volute Casings

Figures ND-3423-1 and ND-3423-2 show typical single and double volute casings, respectively.

ND-3424 Seal Housing

A *seal housing* is defined as that portion of the pump cover or casing assembly which contains the seal and forms a part

of the primary pressure boundary.

ND-3425 Typical Examples of Pump Types

Figures ND-3441.1-1 through ND-3441.9-2 are intended to be typical examples to aid in the determination of a pump type and are not to be considered as limiting. Bearing locations and inlet and outlet orientations are optional.

ND-3430 DESIGN REQUIREMENTS FOR CENTRIFUGAL PUMPS

ND-3431 Design of Welded Construction

(a) The design of welded construction shall be in accordance with ND-3350.

(b) Partial penetration welds, as shown in Fig. ND-4244(e)-1 sketch (c-3) and Fig. ND-4244(f)-1 sketches (a) and (b), are allowed for nozzles such as vent and drain connections and openings for instrumentation. Nozzles shall not exceed NPS 2 (DN 50). For such nozzles, all reinforcement shall be integral with the portion of the shell penetrated. Partial penetration welds shall be of sufficient size to develop the full strength of the nozzles.

**FIG. ND-3423-2 TYPICAL DOUBLE
VOLUTE CASING**

ND-3432 Flanged Connections

[98]

ND-3432.1 Pressure Design

(a) Pumps with flanged connections that are cast integrally with the casing and meet all dimensional requirements (including tolerances) of flanged fittings (as shown in Table ND-3132-1) with regard to the flange dimensions and required wall thicknesses, shall be considered to meet the pressure design requirements of this subarticle and are suitable for use within the pressure-temperature range shown in Appendix I for the material utilized.

(b) Flanged connections not meeting the requirements of (a) shall be designed in accordance with XI-3000 or L-3000.

(c) Pump flanges meeting all requirements of Table ND-3132-1 and welded onto the integral inlets and outlets of the casing, shall be considered as meeting the pressure design requirements of this subarticle,

Page 105

provided that the inlet and outlet wall thicknesses comply with the standard flanged fitting. However, the nozzle-to-flange welds shall meet the requirements of ND-1130.

[98]

ND-3432.2 External Loads.

When external nozzle loads interact with pumps, it is very likely that operability will dictate the maximum allowable loads. The major areas of concern are distortion of the casing and misalignment of driver and driven equipment. The casing shall be capable of withstanding the external loading plus the design pressure, provided in the Design Specification, without distortion that would impair the operation of the pump. In addition, the pump supports shall be capable of accommodating the external loads without sustaining any significant displacements that would cause unacceptable misalignment of rotating parts.

(a) Flanged connections meeting the requirements of ND-3432.1 do not require further analysis when all requirements of ND-3658.2 or ND-3658.3 are met. All other flanged connections shall all meet the requirements of ND-3432.2(b) below.

(b) Flanged connections shall meet the requirements of ND-3658.1.

ND-3433 Reinforcement of Pump Casing Inlets and Outlets

ND-3433.1 Axially Oriented Inlets and Outlets

(a) An axially oriented pump casing inlet or outlet shall be considered similar to an opening in a vessel and shall be reinforced. It shall be treated as required in ND-3330.

(b) To avoid stress concentrations, the outside radius r_2 of Figs. ND-3441.1(a)-1 and ND-3441.3-2 shall not be less than one-half the thickness of the inlets and outlets as reinforced.

ND-3433.2 Radially Oriented Inlets and Outlets.

Reinforcement of radially oriented inlets and outlets is required. The applicable portions of ND-3330 shall apply.

ND-3433.3 Tangential Inlets and Outlets.

Except as modified in ND-3433.4, any design method which has been demonstrated to be satisfactory for the specified Design Loadings may be used.

ND-3433.4 Minimum Tangential Inlet and Outlet Wall Thicknesses.

In Fig. ND-3433.4-1, the value of l , in., shall be determined from the relationship:

In Fig. ND-3433.4-1, the value of l , in., shall be determined from the relationship:

FIG. ND-3433.4-1 MINIMUM TANGENTIAL INLET AND OUTLET WALL THICKNESSES

FIG. ND-3433.4-1 MINIMUM TANGENTIAL INLET AND OUTLET WALL THICKNESSES

$$l = 0.5 \sqrt{r_m t_m}$$

where

$$r_m = r_i + 0.5 t_m \text{ in.}$$

r_i

= maximum inlet or outlet inside radius, in.

$$= d_i/2$$

 t_m

= mean inlet or outlet wall thickness, in., taken between section x-x and a parallel section y-y tangent to crotch radius

The wall thicknesses of the inlet and outlet shall not be less than the minimum wall thickness of the casing for a distance l as shown in Fig. ND-3433.4-1. The wall thickness beyond the distance l may be reduced to the minimum wall thickness of the connected piping. The change in wall thickness shall be gradual and have a maximum slope as indicated in Fig. ND-4250-1.

ND-3434 Bolting

ND-3434.1 Radially Split Configurations.

Bolting in axisymmetric arrangements involving the pressure boundary shall be designed in accordance with the procedure described in Appendix XI. Bolting requirements for Type K pumps are given in ND-3441.9(a)(3) and (b)(1) and for Type L pumps in ND-3441.10(b) and (c).

Page 106

FIG. ND-3436(c)-1 EXTERNAL
AND INTERNAL ATTACHMENTS

FIG. ND-3436(c)-1 EXTERNAL AND INTERNAL ATTACHMENTS

ND-3434.2 Axially Split Configurations.

Bolting in axially split configurations shall be designed in accordance with the procedure given in ND-3441.7 for Type G pumps.

ND-3435 Piping

ND-3435.1 Piping Under External Pressure.

Piping located within the pressure retaining boundary of the pump shall be designed in accordance with ND-3640.

ND-3435.2 Piping Under Internal Pressure.

Piping identified with the pump and external to or forming a part of the pressure retaining boundary, such as auxiliary water connections, shall be designed in accordance with ND-3640.

ND-3436 Attachments

(a) External and internal attachments to pumps shall be designed so as not to cause excessive localized bending stresses or harmful thermal gradients in the pump. The effects of stress concentrations shall be considered.

(b) Attachments shall meet the requirements of ND-3135.

ND-3437 Pump Covers

Pump covers shall be designed in accordance with ND-3325 or ND-3326. Covers for which specific design rules are not given in ND-3325 or ND-3326 shall be designed by any method shown by analysis or experience to be satisfactory.

FIG. ND-3441.1-1 TYPE A PUMP

FIG. ND-3441.1-1 TYPE A PUMP

ND-3438 Supports

Pump supports shall be designed in accordance with the requirements of Subsection NF, unless included under the rules of ND-3411.1(j).

ND-3440 DESIGN OF SPECIFIC PUMP TYPES

ND-3441 Standard Pump Types

ND-3441.1 Design of Type A Pumps.

Type A pumps are those having single volutes and radially split casings with a single suction as illustrated in Fig. ND-3441.1-1 and ND-3441.1-2. Pumps with nozzle sizes NPS 4 discharge and smaller shall be constructed in accordance with ND-3441.1(a) through ND-3441.1(e). Larger pumps are permitted as stipulated in ND-3441.1(f).

(a) *Casing Wall Thickness.* Except where specifically indicated in these rules, no portion of the casing wall shall be thinner than the value of t which is determined as follows:

$$t = (PA)/S$$

or 0.25 in. (6 mm), whichever is greater, where

t	= minimum allowable wall thickness, in.
P	= Design Pressure, psig

Page 107

A	= scroll dimension, in., inside casing as shown in Fig. ND-3441.1(a)-1. If the value of dimension A exceeds 20 in., the formula shall not be used and (f) below applies.
S	= allowable stress, including casting factor, psi (ND-2571 and Tables 1A and 1B, Section II, Part D, Subpart 1)

FIG. ND-3441.1-2 TYPE A PUMP

FIG. ND-3441.1-2 TYPE A PUMP

(b) *Cutwater Tip.* The cutwater tip radius shall not be less than $0.05t$.

(c) *Cutwater Fillets.* All cutwater fillets, including the tips, where they meet the casing wall, shall have a minimum radius of $0.10t$ or 0.25 in. (6 mm), whichever is greater.

(d) *Crotch Radius [Fig. ND-3441.1(a)-I].* The crotch radius shall not be less than $0.3t$.

(e) *Bottom of Casing.* That section of the pump casing within the diameter defined by dimension A in Fig. ND-3441.1(a)-1 on the inlet side of the casing, normally referred to as the bottom of the casing, shall have a wall thickness the greater of t from ND-3441.1(a) or t_b . The value of t_b shall be determined by methods of ND-3300 or Appendix A using the appropriate equations for the casing shape.

(f) Pumps with an "A" dimension greater than 20 in. or nozzles larger than NPS 4 discharge are permitted. Design of these larger pumps must be performed in accordance with Appendix II, Experimental Stress Analysis, or ND-3414. If the design is qualified by analysis, the analysis shall be certified in accordance with NCA-3551.1.

ND-3441.2 Design of Type B Pumps.

Type B pumps are those having single volutes and radially split casings with double suction as illustrated in Fig. ND-3441.2-1. Any design method that has been demonstrated to be satisfactory for the specified Design Conditions may be used.

ND-3441.3 Design of Type C Pumps.

Type C pumps are those having double volutes and radially split casings with a single suction as illustrated in Figs. ND-3441.3-1 and ND-3441.3-2. The splitter is considered a structural part of the casing. Casing design shall be in accordance with the requirements of this Subarticle and with those given in (a) through (e) below.

(a) *Casing Wall Thickness.* Except where specifically indicated in these rules, no portion of the casing wall shall be thinner than the value of t determined as follows:

$$t = (0.5PA)/S$$

where

t	= minimum allowable wall thickness, in.
P	= Design Pressure, psig
A	= scroll dimension, in., inside casing as shown in Fig. ND-3441.3-2
S	= allowable stress, including casting factor, psi (ND-2571 and Tables 1A and 1B, Section II, Part D, Subpart 1)

(b) *Splitter Wall Thickness*

(1) The splitter, which is considered a structural part of the casing, shall have a minimum wall thickness of $0.7t$ as determined above for the casing wall and shall extend from point B in Fig. ND-3441.3-2 sketch (a) through a minimum angle of 135 deg to point C. Beyond point C, the splitter wall may be reduced in thickness and tapered to blend with the cutwater tip radius.

(2) Cutwater tip and splitter tip radii shall not be less than $0.05t$.

(3) All cutwater and splitter fillets, including the tips, where they meet the casing wall, shall have a minimum radius of $0.10t$ or 0.25 in. (6 mm), whichever is greater.

(c) *Crotch Radius (Fig. ND-3441.3-2).* The crotch radius shall not be less than $0.3t$.

(d) *Bottom of Casing.* That section of the pump casing within the diameter defined by dimension A in Fig. ND-3441.3-2 on the inlet side of the casing, normally referred to as the bottom of the casing, shall have a wall thickness no less than the value of t determined in (a) above.

(e) *Alternative Rules for Casing Wall Thickness and Splitter Wall Thickness.* As an alternative to (a) and (b) above, it is permissible to use a smaller casing wall thickness and a larger splitter wall thickness when requirements of (1) through (3) below are met.

FIG. ND-3441.1(a)-1 TYPE A PUMP

FIG. ND-3441.1(a)-1 TYPE A PUMP

FIG. ND-3441.2-1 TYPE B PUMP

FIG. ND-3441.2-1 TYPE B PUMP

FIG. ND-3441.3-1 TYPE C PUMP

FIG. ND-3441.3-1 TYPE C PUMP

FIG. ND-3441.3-2 TYPE C PUMP

FIG. ND-3441.3-2 TYPE C PUMP

FIG. ND-3441.4(a)-1 TYPE D PUMP

FIG. ND-3441.4(a)-1 TYPE D PUMP

(1) The casing wall thickness, as determined by (a) above, shall be maintained at a minimum t , in., between the tangent point of the crotch radius to a point D radially opposite the splitter tip [Fig. ND-3441.3-2 sketch (b)]. The casing wall shall be decreased uniformly to point E from which point a minimum thickness of $0.7t$ shall be continued around the casing wall to a point on the discharge nozzle a distance l , in., from the crotch, where l is defined in Fig. ND-3433.4-1.

(2) The splitter wall thickness shall be as defined in (b) above, except that the splitter shall have a minimum thickness of t , in., instead of $0.7t$.

(3) The requirements of (b)(2) and (b)(3) above shall apply.

ND-3441.4 Design of Type D Pumps

(a) Type D pumps are those having double volutes and radially split casings, with double suction as illustrated in Fig. ND-3441.4(a)-1. Their design shall be in accordance with the applicable requirements of ND-3400.

(b) The requirements of ND-3441.3(a), (b), and (c), governing casing wall thickness, splitter wall thickness, and crotch radius, apply.

(c) In the casing portion between the cover and the casing wall, a wall thickness in excess of t may be required.

ND-3441.5 Design of Type E Pumps.

Type E pumps are those having volute type radially split casings and multivane diffusers which form a structural part of the casing as illustrated in Fig. ND-3441.5-1. The design shall be in accordance with the applicable requirements of ND-3400.

ND-3441.6 Design of Type F Pumps

(a) Type F pumps are those having radially split, axisymmetric casings with either tangential or radial outlets as illustrated in Fig. ND-3441.6(a)-1. The basic configuration of a Type F pump casing is a shell with a dished head attached at one end and a bolting flange at the other. The outlet may be either tangent to the side or normal to the center line of the casing. Variations of these inlet and outlet locations are permitted.

FIG. ND-3441.5-1 TYPE E PUMP

FIG ND-3441.5-1 TYPE E PUMP

FIG. ND-3441.6(a)-1 TYPE F PUMP

FIG ND-3441.6(a)-1 TYPE F PUMP

(b) The design of Type F pumps shall be in accordance with the applicable requirements of ND-3400.

FIG. ND-3441.7(a)-1 AXIALLY SPLIT CASING, VOLUTE PUMP, TYPE G

FIG. ND-3441.7(a)-1 AXIALLY SPLIT CASING, VOLUTE PUMP, TYPE G

ND-3441.7 Design of Type G Pumps¹⁸

(a) Type G pumps are those having axially split, single or double volute casings [Figs. ND-3441.7(a)-1 and ND-3441.7(a)-2].

(b) Manufacturers proposing this design should thoroughly review nondestructive examination requirements for compatibility.

(c) An acceptable method for calculating the stress in the most highly stressed section of the pump case, such as the section with the greatest span, is given in (1) and (2) below. This method is not acceptable for those designs in which more than one bolt falls within a given section [Fig. ND-3441.7(c)-1, Section B-B].

(1) The following assumptions are made:

(a) assign one bolt to Section X , assign one-half bolt to Section Y and one-half bolt to Section Z Section Z is identical to Section Y ;

(b) the flange and bolts act together in bending;

(c) the maximum moment occurs at the bolt;

(d) the total moment is distributed between the flange and case in proportion to their moments of inertia.

(2) Typical sections are shown in Figs. ND-3441.7(c)(2)-1, ND-3441.7(c)(2)-2, and ND-3441.7(c)(2)-3. The procedure for the calculation is given in (a) through (o) below.

18 It is recognized that other acceptable procedures may exist which also constitute adequate design methods, and it is not the intention to rule out these alternative methods provided they can be shown to have been satisfactory by actual service experience.

(a) Establish Design Pressure P , psi. Establish dimensions A , B , C , F , R , t_c , t_f , w , and b from Fig. ND-3441.7(c)(2)-1, ND-3441.7(c)(2)-2, or ND-3441.7(c)(2)-3 and determine the following:

A_G	= effective gasket area, sq in.
D	= diameter of bolt hole, in.
G	= $B + 0.5t_c$, in.
R	= $C - (B + t_c)$, in.
w	= section width, in.
W	= load used in calculating preliminary bolt stress, lb
	= W_X , W_Y , W_Z
d	= bolt root diameter, in.
A_b	= bolt root area, sq in.
y	= gasket design seating stress, psi (Table XI-3221.1-1)
m	= gasket factor (Table XI-3221.1-1)
E	= modulus of elasticity of bolt at service temperature, psi
e	= unit thermal elongation of bolt, in./in.
DTF	= Design Temperature, °F
S_b	= allowable stress, bolt, psi
S_c	= allowable stress, case, psi

**FIG. ND-3441.7(a)-2 AXIALLY SPLIT
CASING, VOLUTE PUMP, TYPE G**

FIG. ND-3441.7(a)-2 AXIALLY SPLIT CASING, VOLUTE PUMP, TYPE G

(b) Determine the effective gasket area A_G sq in., for Sections X and Y :

$$A_G = [(A - F)w - (\pi D^2/4)]C \times K$$

For the factor K , use 0.20 if case face is crowned for greatest contact pressure at inner edge; for flat surfaces, use 0.50.

(c) Determine bolt load, lb, and preliminary bolt stress σ_{PRE} psi:

FIG. ND-3441.7(c)-1 AXIALLY SPLIT CASING, VOLUTE PUMP, TYPE G
Section B — B Typical Highly Stressed Sections of Pump Case

FIG. ND-3441.7(c)-1 AXIALLY SPLIT CASING, VOLUTE PUMP, TYPE G

SECTION OF TYPE G PUMP**

FIG. ND-3441.7(c)(2)-1 TYPICAL SECTION OF TYPE G PUMP

**FIG. ND-3441.7(c)(2)-2 TYPICAL
SECTION OF TYPE G PUMP**

FIG. ND-3441.7(c)(2)-2 TYPICAL SECTION OF TYPE G PUMP

FIG. ND-3441.7(c)(2)-3 TYPICAL LOADS ON TYPE G PUMP

FIG. ND-3441.7(c)(2)-3 TYPICAL LOADS ON TYPE G PUMP

$$H = G \times w \times P$$

$$H_p = A_G \times m \times P$$

$$W_{m1} = H + H_p$$

$$W_{m2} = 0.5 A_G y$$

$$W = \text{greater of } W_{m1} \text{ or } W_{m2}$$

$$\sigma_{PRE} = W/A_b$$

(d) Determine the total load H_o lb:

$$H_D = B \times w \times P$$

$$H_G = H_p$$

$$H_T = H - H_D$$

$$H_o = H_D + H_G + H_T$$

(e) Determine the lever arms h_D , h_G and h_T , in.:

$$h_D = R + 0.5t_c$$

$$h_G = h_D$$

$$h_T = 0.5 (R + t_c + h_G)$$

(f) Determine the total moment M_o in.-lb:

$$M_D = H_D h_D$$

$$M_G = H_G h_G$$

$$M_T = H_T h_T$$

$$M_o = M_D + M_G + M_T$$

(g) Determine the moments of inertia, in.⁴, I_F (flange), I_B (bolt), I_C (case), and I_T (total):

$$I_F = [w(t_f)^3/12] - [D(t_p)^3/12]$$

$$I_B = 0.049d^4$$

$$I_C = w(t_c)^3/12$$

$$I_T = I_F + I_B + I_C$$

(h) Determine the moments, in.-lb, carried M_F (flange), M_B (bolt), and M_C (case):

$$M_F = (M_o I_F)/I_T$$

$$M_B = (M_o I_B)/I_T$$

$$M_C = (M_o I_C)/I_T$$

(i) Determine the resultant bolt load F_R lb:

$$F_R = [H_D(b + h_D) + H_G(b + h_G) + H_T(b + h_T) - M_C - M_B]/b$$

or

$$F_R = H_o + [(M_o - M_C - M_B)/b]$$

(j) Determine resultant bolt stresses, psi:

$$\sigma_{\text{Load}} = F_R/A_b$$

$$\sigma_{\text{Temp}} = eE$$

$$\sigma_{\text{Tensile}} = \sigma_{\text{Load}} + \sigma_{\text{Temp}}$$

$$\sigma_{\text{Bending}} = M_B d/2I_B$$

(k) Determine the shear and bending flange stresses σ_s' , psi, and σ_b' , psi, respectively:

$$\sigma_s' = H_o / wt_f$$

$$\sigma_b' = M_F t_f / 2I_F$$

(l) Determine the tensile and bending case stresses σ_t'' , psi, and σ_b'' , psi, respectively:

$$\sigma_t'' = H_D / wt_C$$

$$\sigma_b'' = M_C t_C / 2I_C$$

TERMS

(m) Use the following method for combining stresses in combined sections.

Let F_X load on Section X, lb

F_Y load on section Y, etc., lb

Let S_X stress in section X, psi

S_Y stress in section Y, etc., psi

Then the combined stress S_{COMB} is as follows:

$$S_{\text{COMB}} = (F_X + F_Y) / [(F_X/S_X) + (F_Y/S_Y)], \text{ etc.}$$

(n) Determine the maximum stresses using (1) through (4) below.

(1) To determine the preliminary bolt stress, establish the load W and stress σ_{PRE} for Section X and for Section (Y + Z):

$$\sigma_{\text{PRE}_{\text{COMB}}} = \frac{W_X + W_{(Y+Z)}}{\frac{W_X}{\sigma_{\text{PRE}_X}} + \frac{W_{(Y+Z)}}{\sigma_{\text{PRE}_{(Y+Z)}}}}$$

The allowable limit for this stress is S_b .

(2) To determine the resultant bolt stress, establish the load F_R and the stresses σ_t and σ_b for Section X and for Section $(Y+Z)$:

$$\sigma_{t_{\text{COMB}}} = \frac{F_{R_X} + F_{R_{(Y+Z)}}}{\frac{F_{R_X}}{\sigma_{t_X}} + \frac{F_{R_{(Y+Z)}}}{\sigma_{t_{(Y+Z)}}}}$$

The allowable limit for $\sigma_{t_{\text{COMB}}}$ is $2S_b$.

$$\sigma_{b\text{ COMB}} = \frac{F_{R_X} + F_{R_{(Y+Z)}}}{\frac{F_{R_X}}{\sigma_{b_X}} + \frac{F_{R_{(Y+Z)}}}{\sigma_{b_{(Y+Z)}}}}$$

The allowable limit for $\sigma_{b\text{ COMB}}$ is $3S_b$.

(3) To determine the flange stresses, establish the load H_o , the shear stress σ'_s , and the bending stress σ'_b for Section X and for Section (Y + Z):

$$\sigma'_{s\text{ COMB}} = \frac{\frac{H_{o_X} + H_{o_{(Y+Z)}}}{\sigma'_{s_X} + \frac{H_{o_{(Y+Z)}}}{\sigma'_{s_{(Y+Z)}}}}}{\sigma'_{b_X} + \frac{H_{o_{(Y+Z)}}}{\sigma'_{b_{(Y+Z)}}}} \sigma'_{b\text{ COMB}} = \frac{H_{o_X} + H_{o_{(Y+Z)}}}{\sigma'_{b_X} + \frac{H_{o_{(Y+Z)}}}{\sigma'_{b_{(Y+Z)}}}}$$

$$\sigma'_{s\text{ max}} = [(\sigma'_{s\text{ COMB}})^2 + (\sigma'_{b\text{ COMB}}/2)^2]^{1/2}$$

$$\sigma'_{n\text{ max}} = \sigma'_{s\text{ max}} + (\sigma'_{b\text{ COMB}}/2)$$

where $\sigma'_{n\text{ max}}$ is the maximum normal stress. The allowable limit for $\sigma'_{s\text{ max}}$ is S_c and the allowable limit for $\sigma'_{n\text{ max}}$ is $1.5S_c$.

TERM

(4) To determine the case stresses, establish the load H_D , the tensile stress σ_t'' , and the bending stress σ_b'' for Section X and for Section (Y + Z):

$$\sigma_t''_{\text{COMB}} = \frac{H_{D_X} + H_{D_{(Y+Z)}}}{\frac{H_{D_X}}{\sigma_t''_X} + \frac{H_{D_{(Y+Z)}}{\sigma_t''_{(Y+Z)}}}$$

$$\sigma_b''_{\text{COMB}} = \frac{H_{D_X} + H_{D_{(Y+Z)}}}{\frac{H_{D_X}}{\sigma_b''_X} + \frac{H_{D_{(Y+Z)}}{\sigma_b''_{(Y+Z)}}}$$

The allowable limit for $\sigma_t''_{\text{COMB}}$ is S_c . The total stress is $\sigma_t''_{\text{COMB}} + \sigma_b''_{\text{COMB}}$. The allowable limit for total stress is $1.5S_c$.

TERM

(o) The above procedure will generally show some bolt stresses in excess of the indicated allowable values. Under these circumstances it is permissible to average bolt stresses between adjacent bolts. Such averaged stresses shall not exceed the specified allowables.

ND-3441.8 Design of Type H Pumps.

Type H pumps are those having axially split, barrel type casings (Figs. ND-3441.8-1 and ND-3441.8-2) and radially split covers. The axially split casing shall be designed in accordance with the rules of ND-3441.7 for Type G

Page 115

pumps. The radially split cover shall be designed in accordance with the rules of ND-3437.

**FIG. ND-3441.8-1 LONGITUDINAL SECTION
THROUGH TYPE H PUMP**

FIG. ND-3441.8-1 LONGITUDINAL SECTION THROUGH TYPE H PUMP

**FIG. ND-3441.8-2 TRANSVERSE SECTION
THROUGH TYPE H PUMP**

FIG. ND-3441.8-2 TRANSVERSE SECTION THROUGH TYPE H PUMP

ND-3441.9 Design of Type K Pumps.

Type K pumps are vertical pumps having a radially split casing with one or more internal pump stages, as illustrated in Figs. ND-3441.9-1 and ND-3441.9-2. The basic configuration is a casing which forms the pressure boundary and consists of a barrel and a head joined by bolted flanges. There is an inner assembly consisting of internal chambers of the head, one or more bowls, column sections, and a suction bell, all joined by bolted flanges and arranged so that the external surfaces of these parts are subjected to inlet pressure. These pumps may be furnished with or without column(s) and with or without lateral restraints between the inner assembly and outer casing.

(a) *Flanged Joints.* Except for flanged joints conforming to (5), flanged joints may be analysed and the stresses evaluated by using methods given in Appendix XI if of the "RF" type and in accordance with Appendix L if of the "FF" type, as modified by (1) through (4) below or by (5) below.

(1) The Design Pressure to be used for the calculation of H in Appendix XI or Appendix L shall be replaced by the flange design pressure:

$$(1) P_{FD} = P + P_{eq}$$

where

P = Design or Service Condition Pressure as defined in NCA-2140, psi

P_{eq} = Equivalent pressure to account for the axial force and moments applied to the flange joint, psi

The equivalent pressure, P_{eq} , shall be determined from the seismic and external loads acting on the flanged joint using the equation:

$$P_{eq} = \frac{KM_f}{\pi G^3} + \frac{4F}{\pi G^2} \quad (2)$$

(2)

where

M_f = the resultant bending moment on the flange as taken from paragraph ND-3658, in.-lb_f

F = the axial load at the flange, lb_f

G = the diameter at the location of the gasket load reaction, in.

K = If the loads include dynamic loads the value of this coefficient shall be 8. If the loads are static the value shall be 16.

(2) Equations (3) and (4) in Appendix XI-3223 or Appendix L-3221 shall be used to establish minimum bolt area required using allowable stress values given in Tables 1A and 1B, Section II, Part D, Subpart 1.

(3) Equation (6) in Appendix XI-3240 for longitudinal hub stress shall be revised to include primary axial membrane stress as follows:

$$S_H = \frac{fM_o}{Lg_1^2B} + \frac{PB}{4g_o} \quad (3)$$

(3)

Where P is the Design or Service Pressure as defined in NCA-2140, psi. Other terms are defined in XI-3130.

(4) The allowable stress limits shall be:

S_H not greater than $1.5S$

S_R not greater than $1.5S$

Page 116

Page 117

FIG. ND-3441.9-1 TYPE K PUMP

S_T not greater than $1.5S$

FIG. ND-3441.9-2 TYPE K PUMP

FIG. ND-3441.9-2 TYPE K PUMP

(5) If the flanged joint conforms to one of the standards listed in Table ND-3132-1 and if each P_{FD} as calculated by (1) is less than the rated pressure at the Design or Service Temperature utilized, the requirements of this subparagraph are satisfied.

(b) *Casing*. The barrel and head of the casing shall be designed in accordance with the requirements of ND-3400 and with those given in (1) and (2) below.

(1) *Barrel*. The Design Pressure for the barrel shall be the pump inlet pressure or as otherwise stated in the Design Specification (NCA-3250), but in no case shall it be less than the maximum pressure at the pump inlet under any Service Condition. The static pressure head shall be considered in the selection of the Design Pressure.

The inlet nozzle loads shall include the Design Pressure and piping moments. The equivalent pressure shall be determined using Eq. (1), with $F = 0$ in Eq. (2), as applied to the inlet geometry.

The barrel shall be designed in accordance with the requirements of ND-3320 for pressure vessels.

(2) *Head*

(a) The external walls of the head, which form the pressure boundary shall be designed for the pressures specified in (b) and (c) below. The Design Pressure for the internal chambers shall be as specified under the inner assembly rules.

(b) The Design Pressure P , for the portions of the head that form the pressure boundary between the outlet pressure and the atmosphere shall be the outlet pressure or as otherwise stated in the Design Specification, but in no case shall it be less than the maximum pressure at the pump outlet under any Service Condition.

The minimum thickness of the head waterway required for Design Pressure and for temperatures not exceeding those for various materials in Tables 1A and 1B, Section II, Part D, Subpart 1 shall be not less than that determined by the formula:

$$t_m = \frac{P D_o}{2(SE + Py)} + A \quad (4)$$

(4)

where

t_m	= minimum required wall thickness of the head waterway in its finished form, in.
D_o	= the outside diameter of the head waterway, in.
S	= the allowable stress for the material at the design temperature (Tables 1A and 1B, Section II, Part D, Subpart 1), psi
E	= the joint efficiency for the type of longitudinal joint used, as given in ND-3350 or casting quality factor as given in the

notes to Tables 1A and 1B, Section II, Part D, Subpart 1

= 0.4 for D_o/t_m greater or equal to 6.0

=

$$\frac{d}{d + D_o} \text{ for } \frac{D_o}{t_m} \text{ less than 6.0}$$

d = inside diameter of the head waterway, in.

A = corrosion or erosion allowance as specified by the Design Specification, in. If both surfaces are wetted, the corrosion allowance must be applied to both surfaces.

The above head waterway minimum thickness is in its finished form. If curved segments of pipe are used as the waterway, the minimum wall thickness after bending shall be not less than the required value.

The discharge nozzle loads shall include the Design Pressure and piping moments. The equivalent pressure shall be determined using Eq. (1), with $F = 0$ in Eq. (2), as applied to the head geometry.

(c) The Design Pressure for the portions of the head that form the pressure-containing boundary between the inlet pressure and the atmosphere shall be the inlet pressure or as otherwise stated in the Design Specification, but in no case shall it be less than the maximum pressure at the pump inlet under any Service Condition.

This portion of the head shall be designed in accordance with ND-3320 for pressure vessels.

(c) *Inner Assembly.* The inner assembly consists of those elements of the pump subjected to differential pressure within the pump. This assembly comprises the internal chambers of the head, the bowls and columns, and the upper flange of the suction bell.

Because of the installation and operation, pumped fluids within the inner assembly may transfer through the flanged connections back to the inlet fluid source. This fluid transfer does not effect the integrity of the overall pressure boundary but may result in a higher Design Pressure for the barrel and portions of the head and shall be considered in the determination of the barrel Design Pressure.

The Inner Assembly of Type K pumps shall be designed in accordance with the requirements of ND-3400 and with those given in (1) through (3) below. Alternatively, the configuration may be designed in accordance with Appendix II, Design by Experimental Stress Analysis, or Appendix XIII, Design by Stress Analysis.

(1) *Columns.* The Design Pressure for columns, P_c (psi), shall include the piping moments and axial loads. It shall be not less than the maximum differential

Page 119

pressure which can be developed across the wall of that column under any Service Condition. The weight of the pump bowls and impeller thrust shall be taken into consideration. P_c shall be determined using Eq. (1) and (2) but with "G" equal to the average column shell diameter.

The minimum thickness of the column shall be not less than that determined by the equation:

$$t_m = \frac{P_c D_o}{2(SE + P_y)} + A \quad (5)$$

(5) where the terms are as defined in ND-3441.9(b)(2)(b), but as applied to the column geometry and material.

(2) *Column Flanges.* Flanged joints in the column shall be designed in accordance with ND-3441.9(a) except that the design pressure shall be P_c . The equivalent pressure shall be determined using Eq. (1) as applied to the column geometry and shall be not less than the maximum differential pressure which can be developed across the wall of that column under any Service Condition. Unpacked flange joints are permitted.

(3) *Bowls.* The Design Pressure for the bowl(s), P_b shall include the piping moments. The equivalent pressure shall be determined using Eq. (1), with $F = 0$ in Eq. (2), as applied to the bowl geometry and shall be determined as the maximum differential pressure to which the bowl may be subjected under any Service Condition.

The design of the bowls shall be completed in accordance with (a) through (c) below for unribbed bowl geometries. For those bowl geometries which use external ribs to increase bowl and flange stiffness the design shall be completed using methods which have been proven in actual service. Unless special provisions are made to insure that interchangeability between bowls is prevented all bowls shall be designed to the same requirements.

(a) *Bowl Minimum Thickness.* The minimum thickness of the bowl shell, remote from discontinuities, shall be not less than that determined by:

$$t_m = \frac{P_b D_o}{2(SE + P_{by})} + A \quad (6)$$

(6)

where the terms are as defined in ND-3441.9(b)(2)(b) but as applied to the bowl geometry and material and:

D_o = the largest outside diameter of the bowl, taken at the suction end of the individual bowl assembly, (Fig. ND-3441.10-2), in.

The above minimum bowl thickness is applicable only to a location within the bowl which is remote from discontinuities and may have to be increased in order to satisfy the local evaluations of (b) and (c) below.

(b) *Vane/Shell Interaction.* Consideration shall be given to the restraining effect of the diffuser vanes on the radial expansion of the shell due to internal pressure. An acceptable method of accounting for this effect is presented below:

$$F_D = \frac{2 (2 - \mu) P_b A_D^2}{\frac{16 l_D t_D}{t_v} + \frac{t_D (\pi A_D)^3}{(n_v t_D)^3}} \quad (7)$$

(7)

where

F_D	= vane load/unit length, lb _f /in.
P_b	= the maximum internal bowl differential pressure, psi.
A_D	= the mean diameter of the vaned portion of the bowl as defined in Fig. ND-3441.10-2, in.
l_D	= the radial mean vane length as defined in Fig. ND-3441.10-2, in.
t_v	= the mean vane thickness, in.
t_D	= the shell thickness at the vane-shell intersection as defined in Fig. ND-3441.10-2, in.
n_v	= the number of vanes in the bowl waterway
μ	= Poisson's ratio

The local shell bending stress, σ_B , shall be less than 1.5 SE. Its value is determined by the equation:

$$\sigma_B = \frac{3 F_D \pi A_D}{n_v t_D^2} \quad (8)$$

(8)

The vane membrane stress, σ_v , shall be less than SE as determined by the equation:

$$\sigma_v = \frac{F_D}{t_v} \quad (9)$$

(9)

(c) *Bowl Flanges.* The flange joint between the individual bowl discharge flange and the next stage bowl inlet flange is usually such that the outlet flange rotational restraint is insufficient to restrict outlet flange rotation. Therefore, the prying action between flat faced flanges can be ignored and the outlet flange shall be analyzed in accordance with Appendix XI. This may not be true for ribbed flanges or the last stage bowl which attaches to the column assembly. If any of these joints have sufficient rigidity to support the prying action it shall be analyzed as an Appendix L flange. The analysis shall be in accordance with ND-3441.9(a) using Eq. (1), with $F = 0$ in Eq. (2). The definition

Page 120

of the outlet flange geometry for the analysis is shown in Fig. ND-3441.10-2.

The minimum radial distance between the bolt circle and the outside of the bowl or the inside rabbet fit shall be equal to or greater than one bolt diameter.

(4) *Suction Bell.* The Design Pressure for the suction bell, P_{sb} , shall be determined as the sum of the differential pressure developed at the first stage of the pump under any service condition plus an equivalent pressure to account for moments on the suction bell. The equivalent pressure shall be calculated using Eq. (1), with $F = 0$ in Eq. (2). The suction bell pressure, P_{sb} , is applied only to the suction bell flange. Below the suction bell flange (the section above line A-A in Figs. ND-3441.9-1 and ND-3441.9-2), the remaining portions of the bell are not considered subject to a differential pressure.

ND-3441.10 Design of Type L Pumps.

Type L pumps are vertical pumps of one or more stages, having a radially split casing as illustrated in Fig. ND-3441.10-1. The basic configuration consists of a head with an attached support plate, one or more bowls and column sections, and a suction bell, all joined by flanges. These pumps may be furnished with or without column. External restraint may be provided at various locations to restrain vibratory motions and resist external loads.

The configuration is such that the external surfaces of those parts above the support plate are subjected to atmospheric pressure. The parts below the support plate may be subjected to atmospheric pressure, or atmospheric pressure plus submerged head pressures. Because of the installation and operation, pumped fluids within the bowl and column assemblies may transfer through the flanged connections back to the fluid source. This fluid transfer does not effect the integrity of the overall pressure boundary.

Type L pumps shall be designed in accordance with the requirements of ND-3400 and with those given in (a) through (e) below. Alternatively, the configuration may be designed in accordance with Appendix II, Design by Experimental Stress Analysis, or Appendix XIII, Design by Stress Analysis.

(a) *Flanged Joints.* Except for flanged joints conforming to (5) below, flanged joints may be analysed and the stresses evaluated by using methods given in Appendix XI if of the "RF" type and in accordance with Appendix L if of the "FF" type, as modified by (1) through (4) below.

(1) The Design Pressure to be used for the calculation of H in Appendix XI or Appendix L shall be replaced by the flange design pressure:

$$(1) P_{FD} = P + P_{eq}$$

where

P	= Design or Service Condition Pressure as defined in NCA-2140, psi
P_{eq}	= Equivalent pressure to account for the moments applied to the flange joint, psi

The equivalent pressure P_{eq} shall be determined from the seismic and external loads acting on the flanged joint using the equation:

$$P_{eq} = \frac{KM_f}{\pi G^3} + \frac{PB}{\pi G^2} \quad (2)$$

(2)

where

M_f	= the resultant bending moment on the flange as taken from paragraph ND-3658, in.-lbf
F	= the axial load at the flange, lb
G	= the diameter at the location of the gasket load reaction, in.
K	= If the loads include dynamic loads the value of this coefficient shall be 8. If the loads are static the value shall be 16.

(2) Equations (3) and (4) in Appendix XI-3223 or Appendix L-3221 shall be used to establish minimum bolt area required using allowable stress values given in Tables 1A and 1B, Section II, Part D, Subpart 1.

(3) Equation (6) in Appendix XI-3240 for longitudinal hub stress shall be revised to include primary axial membrane stress as follows:

$$S_H = \frac{fM_o}{Lg_1^2B} + \frac{PB}{4g_o} \quad (3)$$

(3)

where P is the Design or Service Pressure as defined in NCA-2140, (psi). Other terms are defined in Appendix XI-3130.

(4) The allowable stress limits shall be:

S_H not greater than $1.5S$

S_R not greater than $1.5S$

S_T not greater than $1.5S$

(5) If the flanged joint conforms to one of the standards listed in Table ND-3132-1 and if each P_{FD} as calculated by Eq. (1) is less than the rated pressure at the Design or Service Temperature utilized, the requirements of this subparagraph are satisfied.

(b) *Head Waterway.* The Design Pressure P for portions of the head which form the pressure boundary between the outlet pressure and the atmosphere shall be the outlet pressure or as otherwise stated in the Design Specification. In no case shall it be less than the maximum pressure at the pump outlet under any

Page 121

Service Condition. The minimum thickness of the head waterway required for Design Pressure and for temperatures not exceeding those for various materials in Tables 1A and 1B, Section II, Part D, Subpart 1 shall be not less than that determined by the formula:

$$t_m = \frac{PD_o}{2(SE + Py)} + A \quad (4)$$

(4)

FIG. ND-3441.10-1 TYPE L PUMP

FIG. ND-3441.10-1 TYPE L PUMP

where

t_m	= minimum required wall thickness of the head waterway in its finished form, in.
D_o	= the outside diameter of the head waterway, in.
S	= the allowable stress for the material at the design temperature (Tables 1A and 1B, Section II, Part D, (Subpart 1), psi
E	= the joint efficiency for the type of longitudinal joint used, as given in ND-3350 or casting quality factor as given in the notes to Tables 1A and 1B, Section II, Part D, Subpart 1
y	= 0.4 for $D_o/t_m \geq 6.0$
y	=

$$\frac{d}{d + D_o} \text{ for } D_o/t_m < 6.0$$

d	= inside diameter of the head waterway, in.
A	= corrosion or erosion allowance as specified by the Design Specification, in. If both surfaces are wetted, the corrosion allowance must be applied to both surfaces.

The above head waterway minimum thickness is in its finished form. If curved segments of pipe are used as the waterway, the minimum wall thickness after bending shall be not less than the required value.

(c) *Column.* The Design Pressure for the column P_c shall include the effects of the piping moments and axial loads. It shall be not less than the maximum differential pressure which can be developed across the wall of that column under any Service Condition. The weight of the pump bowls and impeller thrust shall be taken into consideration. P_c shall be determined using Eq. (1) and (2) but with "G" equal to the average column shell diameter.

(1) *Column Thickness.* The minimum thickness of the column shall be not less than that determined by the equation:

$$t_m = \frac{P_c D_o}{2(SE + Py)} + A \quad (5)$$

(5) where the terms are as defined in (b) above, except as applied to the column geometry and material.

(2) *Column Flanges.* Flanged joints in the column shall be designed in accordance with ND-3441.10(a) except that the design pressure shall be P_c . The equivalent pressure shall be determined using Eq. (1) as applied to the column geometry and shall be not less than the maximum differential pressure which can be developed across the wall of that column under any Service Condition. Unpacked flange joints are permitted.

(d) *Bowls.* The Design Pressure for the bowl(s) P_b shall be determined as the maximum differential pressure to which the bowl may be subjected under any service condition.

The design of the bowls shall be completed in accordance with (1) through (3) below for unribbed bowl geometries. For those bowl geometries which use external ribs to increase bowl and flange stiffness, the design shall be completed using methods which have been proven in actual service. In both cases, the pump bowl experiencing the largest load shall be used in the design. Unless special provisions are made to insure that interchangeability between bowls is prevented, all bowls shall be designed to the same requirements.

(1) *Bowl Minimum Thickness.* The minimum thickness of the bowl shell, remote from discontinuities, shall be not less than that determined by:

$$t_m = \frac{P_b D_o}{2(SE + Py)} + A \quad (6)$$

(6)

where

D_o = the largest outside diameter of the bowl, taken at the suction end of the individual bowl assembly (Fig. ND-3441.10-2)

The above minimum bowl thickness is applicable only to a location within the bowl which is remote from discontinuities and may have to be increased in order to satisfy the local evaluations of (2) and (3) below.

(2) *Vane/Shell Interaction.* Consideration shall be given to the restraining effect of the diffuser vanes on the radial expansion of the shell due to internal pressure. An acceptable method of accounting for this effect is presented below.

$$F_D = \frac{2(2 - \mu) P_b A_D^2}{\frac{16l_D t_D}{t_v} + \frac{t_D (\pi A_D)^3}{(n_v t_d)^3}} \quad (7)$$

(7)

where

F_D

= vane load/unit length, lbf/in.

 P_b

= the maximum internal bowl differential pressure, psi

 A_D

= the mean diameter of the vaned portion of the bowl as defined in Fig. ND-3441.10-2, in. The section shall be taken at a portion of the bowl where the hub can be considered essentially solid.

Page 123

Page 124

 l_D

= the radial mean vane length as defined in Fig. ND-3441.10-2, in.

 t_v

= the mean vane thickness, in.

 t_D

= the shell thickness at the vane-shell intersection as defined in Fig. ND-3441.10-2, in.

 n_v

= the number of vanes in the bowl waterway

 μ

= Poisson's ratio

FIG. ND-3441.10-2 TYPE L PUMP BOWL

FIG. ND-3441.10-2 TYPE L PUMP BOWL

The local shell bending stress σ_v shall be less than 1.5 SE. Its value is determined by the equation:

$$\sigma_v = \frac{F_D}{t_v} \quad (8)$$

(8)

(3) *Bowl Flanges.* Flanged joints in the bowls shall be designed in accordance with ND-3441.10(a) except that the design pressure shall be P_b . The equivalent pressure shall be determined using Eq. (1), as applied to the bowl geometry and shall be not less than the maximum differential pressure which can be developed across the wall of that bowl under any Service Condition. Unpacked flange joints are permitted. The flange joint between the individual bowl discharge flange and the next stage bowl inlet flange is usually such that the outlet flange rotational restraint is insufficient to restrict outlet flange rotation. Therefore, the prying action between flat faced flanges can be ignored and the outlet flange shall be analyzed in accordance with Appendix XI. This may not be true for ribbed flanges or the last stage bowl which attaches to the column assembly. The definition of the outlet flange geometry for the analysis is shown in Fig. ND-3441.10-2.

The minimum radial distance between the bolt circle and the outside of the bowl or the inside rabbet fit shall be equal to or greater than one bolt nominal diameter.

(e) *Suction Bell.* The Design Pressure for the suction bell P_{sb} shall be determined as the sum of the differential pressure developed at the first stage of the pump under any service condition plus an equivalent pressure to account for moments on the suction bell. The equivalent pressure shall be calculated using Eq. (1), with $F = 0$ in Eq. (2), except using the geometry of the suction bell. The suction bell pressure, P_{sb} , is applied only to the suction bell flange. Below the suction bell flange (Section A-A of Fig. ND-3441.10-1), the remaining portion of the bell and any strainer basket which may be attached thereto are not considered subject to a differential pressure load.

ND-3442 Special Pump Types

ND-3442.1 Design of Type J Pumps (Centrifugal)

(a) Type J pumps are those that cannot logically be classified with any of the preceding types of centrifugal pumps.

(b) It is not planned to establish rules for Type J pumps, and any design method which has been demonstrated to be satisfactory for the specified Design Conditions may be used.

ND-3442.2 Design of Reciprocating Pumps.

See ND-3450.

ND-3450 DESIGN OF CLASS 3 RECIPROCATING PUMPS

ND-3451 Scope

(a) These rules cover the strength and pressure integrity of the structural parts of the liquid end [Fig. ND-3451(a)-1], whose failure would violate the pressure boundary. Such parts include:

- (1) liquid cylinder and valve chambers
- (2) valve covers
- (3) liquid cylinder heads
- (4) stuffing boxes
- (5) packing glands
- (6) manifolds
- (7) piping and nozzles normally identified with the pump furnished by the pump supplier
- (8) related bolting
- (9) external and internal integral attachments to the pressure retaining boundary

(b) These rules do not apply to the plunger or piston, nonstructural internals, including valves, valve seats, gaskets, packing, and cylinder mounting bolting. Hydrostatic testing of packing glands is not required.

ND-3452 Acceptability

The pressure boundary parts shall be capable of withstanding the specified Design Pressures, and the design shall be such that the requirements of ND-3100 are satisfied in addition to these rules.

ND-3453 Material and Stresses

Material and allowable stresses shall conform to the requirements of ND-2000.

Page 125

Page 126

FIG. ND-3451(a)-1 HORIZONTAL SINGLE-ACTING POWER PUMP LIQUID ENDS

FIG. ND-3451(a)-1 HORIZONTAL SINGLE-ACTING POWER PUMP LIQUID ENDS

ND-3454 Design Requirements

ND-3454.1 Design of Welded Construction

(a) Design of welded construction shall be in accordance with ND-3350.

(b) Partial penetration welds, as shown in Fig. ND-4244(e)-1 sketch (c-3) and Fig. ND-4244(f)-1 sketches (a) and (b), are allowed for nozzles such as vent and drain connections and openings for instrumentation. Nozzles shall not exceed NPS 2 (DN 50). For such nozzles, all reinforcement shall be integral with the portion of the shell penetrated. Partial penetration welds shall be of sufficient size to develop the full strength of the nozzles.

ND-3454.2 Piping.

Piping located within the pressure retaining boundary of the pump, and identified with the pump, shall be designed in accordance with ND-3600.

ND-3454.3 Liquid End.

Any design method which has been demonstrated to be satisfactory for the specified design may be used.

ND-3454.4 Fatigue.

The liquid cylinder and pressure retaining bolting are exposed to significant fatigue loadings which shall be considered in the design. Any design method which has been demonstrated to be satisfactory for the specified design may be used.

ND-3454.5 Earthquake Loadings.

The effects of earthquake shall be considered in the design of pumps. The stresses resulting from these earthquake effects shall be included with the stresses resulting from pressure or other applied loads.

ND-3454.6 Corrosion.

In designs where corrosion of material is a factor, allowances shall be made.

ND-3454.7 Bolting.

Bolting in axisymmetric arrangements involving the pressure boundary shall be designed in accordance with the procedure described in Appendix XI.

ND-3500 VALVE DESIGN

ND-3510 GENERAL REQUIREMENTS

ND-3511 Design Specification¹⁹

¹⁹

CAUTIONARY NOTE: Certain types of double seated valves have the capacity of trapping liquid in the body or bonnet cavity in the closed position. If such a cavity accumulates liquid and is in the closed position at a time when adjacent system piping is increasing in temperature, a substantial and uncontrolled increase in pressure in the body or bonnet cavity may result. Where such a condition is possible, it is the responsibility of the Owner or his designee to provide, or require to be provided, protection against harmful overpressure in such valves.

Design and Service Conditions (NCA-2142) shall be stipulated in the Design Specification (NCA-3250). The requirements of NCA-3254(a) for specifying the location of valve boundary jurisdiction may be considered to have been met by employing the minimum limits of ND-1131, unless the Design Specification extends the boundary of jurisdiction beyond these minimum limits. The requirements of NCA-3254(b) for specifying the boundary conditions are not applicable to valve end connections.

ND-3512 Standard Design Rules

ND-3512.1 Flanged and Butt Welded End Valves.

The design of valves with flanged and butt welded ends shall conform to the applicable requirements for Standard Class category valves of ANSI B16.34 except as provided in (a) and (b) below.

(a) Valves with flanged and butt welding ends may be designated as Class 75 in sizes larger than NPS 24, provided that the following additional requirements are met.

(1) The maximum rated pressure shall be 75 psi (517 kPa) for fluid temperatures from -20°F to 350°F (-29°C to 177°C).

(2) The minimum valve body wall thickness, exclusive of corrosion allowance, shall be in accordance with the following:

$$t_m = 0.4t_o + 0.2 \text{ for } d \leq 50 \text{ in.}$$

or

$$t_m = 0.008d + 0.2 \text{ for } d > 50 \text{ in.}$$

where

t_m = minimum body wall thickness, in.

t_o = minimum body wall thickness as tabulated in ANSI B16.34 for Class 150, in.

d = inside diameter, in.

(3) Flanges shall be designed in accordance with the requirements of Appendix XI, AWWA-C207 Class E (275 psi), MSS-SP-44, or API-605.

(4) The minimum hydrostatic shell test pressure shall be 125 psi (861 kPa) and shall be maintained for a minimum of 10 min.

(5) The minimum valve closure test pressure shall be 85 psi (586 kPa) and shall be maintained for a minimum of 10 min.

Page 127

(b) Valves with flanged ends in sizes larger than NPS 24 may be used, provided that the following additional requirements are met.

(1) For MSS-SP-44 the Pressure Class shall be limited to Class 600 and lower, and for API-605 the Pressure Class shall be limited to Class 150 and Class 300.

(2) The operating temperatures shall be limited to the range of -20°F to 650°F (-29°C to 343°C).

(3) Flanges are designed in accordance with the requirements of Appendix XI, MSS-SP-44, or API-605.

ND-3512.2 Socket Welded End and Nonwelded End Valves.

The design of valves with socket welded end connections and nonwelded piping end connections other than ANSI B16.5 flanges shall conform to the applicable requirements for Standard Class category butt welding valves of ANSI B16.34 except that the end connections shall conform to the applicable requirements of ND-3661 or ND-3671.

ND-3512.3 Wafer or Flangeless Valves.

The design of valves that can be bolted between flanges (i.e., butterfly valves) shall conform to the applicable requirements of Standard Class category valves of ANSI B16.34 and the requirements of (a) through (e) below.

(a) The design shall provide for bolt-up using all of the bolt holes and the bolt circle of the specified flange.

(b) Bolt holes parallel to the body run may be either threaded or unthreaded. Threaded holes may be blind holes suitable for use with bolt studs.

(c) The required minimum valve body wall thickness shall be measured from the valve inside circumference to either the valve outside circumference or the circumference of a circle inscribed about the inner tangents to the bolt holes, whichever is smaller.

(d) The inner ligament of either a through hole or a blind threaded hole in the vicinity of a stem penetration shall not be less than 25% of the required body neck thickness.

(e) The inner ligament for singular holes parallel to the body run shall not be less than 25% of the required valve body wall thickness. Such holes shall not be larger than $\frac{3}{8}$ in. (10 mm) diameter.

ND-3512.4 Design and Service Loadings.

The design requirements of ND-3512.1 and ND-3512.2 include pressure-temperature ratings for Design Loadings and Service Loadings for which Level A Limits are designated. When any Service Loadings are stipulated for which Level B, Level C, or Level D Limits are designated in the Design Specification, the requirements of ND-3520 shall be met.

ND-3512.5 Openings for Auxiliary Connections.

Openings for auxiliary connections, such as for drains, bypasses, and vents, shall meet the requirements of ANSI B16.34 and the applicable requirements of ND-3330.

ND-3513 Alternative Design Rules

For butt welding end valves and for socket welding end valves whose end connections conform to the requirements of ND-3661, the design requirements for Special Class category valves of ANSI B16.34 may be used in place of ND-3512 when permitted by the Design Specification, provided that the following requirements are met.

(a) The nondestructive examination requirements of ANSI B16.34, Special Class, shall be met for all sizes of butt welding and socket welding end valves in accordance with the examination methods and acceptance standards of ND-2500.

(b) When any Service Loadings are stipulated for which Level B, Level C, or Level D Limits are designated in the Design Specification, the requirements of ND-3520 shall be met.

(c) Openings for auxiliary connections, such as for drains, bypasses, and vents, shall meet the requirements of ANSI B16.34 and the applicable reinforcement requirements of ND-3330.

ND-3515 Acceptability of Metal Bellows and Metal Diaphragm Stem Sealed Valves

Valves using metal bellows or metal diaphragm stem seals shall be constructed in accordance with the rules of this Subarticle, based on the assumption that the bellows or diaphragms do not retain pressure and Design Pressure is imposed on a required backup stem seal such as packing. The bellows or diaphragms need not be constructed in accordance with the requirements of this Section.

ND-3516 Acceptability of Elastomer Diaphragm Valves

Valves using elastomer diaphragms, wherein the diaphragm performs the function of a disc or plug, shall be constructed in accordance with ND-3500. This is based on the assumptions that the diaphragms do not retain pressure, design pressure is imposed on the backup stem seal, and the following additional requirements are met.

(a) Design temperature shall not exceed 350°F (177°C).

(b) Valve size and Pressure Class shall not exceed NPS 12 (DN 300) for Class 150 and NPS 4 (DN 100) for Class 300.

(c) A backup stem seal shall be provided.

(d) Diaphragms shall meet the requirements of MSS SP-100.

ND-3520 LEVEL B, C, AND D SERVICE LIMITS

ND-3521 Design Requirements

(a) When the piping system in which the valve is located is designed to the requirements of ND-3600, the valve body is considered adequate to withstand piping end loads provided that conditions (1) and (2) below are satisfied. In lieu of (1) and (2), the design procedure of NB-3545.2 is acceptable.

(1) The section modulus and metal area at a plane normal to the flow passage through the region at the valve body crotch, that is, in the plane A-A of Fig. ND-3521-1, shall be not less than 110% of the section modulus and metal area of the piping connected to the valve body inlet and outlet nozzles.

(2) The allowable stress for valve body material is equal to or greater than the allowable stress of the connected piping material. If the valve body material allowable stress is less than that of the connected piping material, the valve section modulus and metal area shall be not less than 110% of the section modulus and metal area of the connected piping multiplied by the ratio $S_{\text{pipe}}/S_{\text{valve}}$.

(b) The maximum internal pressure resulting from Service Loadings for which Level B, Level C, or Level D Limits are designated shall not exceed the tabulated factors in Table ND-3521-1 times the Design Pressure or the rated pressure at the applicable service temperature. If these pressure limits are met, loadings for the stress limits in Table ND-3521-1 are considered to be satisfied.

(c) Where valves are provided with operators having extended structures and these structures are essential to maintaining pressure integrity, an analysis, when required by the Design Specification, shall be performed based on static forces resulting from equivalent earth quake accelerations acting at the centers of gravity of the extended masses. The valve bodies shall conform to the stress limits listed in ND-3522. Classical bending and direct stress equations, where free body diagrams determine a simple stress distribution that is in equilibrium with the applied loads, may be used.

TABLE ND-3521-1
LEVEL A, LEVEL B, LEVEL C, AND LEVEL D
SERVICE LIMITS

Service Limit	Stress [Note (1)] Limits [Notes (2)–(5)]	$P_{\max}$ [Note (6)]
Level A	$\sigma_m \leq 1.0S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.5S$	1.0
Level B	$\sigma_m \leq 1.1S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.65S$	1.1
Level C	$\sigma_m \leq 1.5S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.8S$	1.2
Level D	$\sigma_m \leq 2.0S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 2.4S$	1.5

NOTES:

- (1) Stress means the maximum normal stress.
- (2) A casting quality factor of 1 shall be assumed in satisfying these stress limits.
- (3) These requirements for the acceptability of valve design are not intended to assure the functional adequacy of the valve.
- (4) Design requirements listed in this table are not applicable to valve disks, stems, seat rings, or other parts of the valves which are contained within the confines of the body and bonnet.
- (5) These rules do not apply to safety relief valves.
- (6) The maximum pressure shall not exceed the tabulated factors listed under $P_{\max}$ times the Design Pressure or times the rated pressure at the applicable service temperature.

TABLE ND-3521-1 LEVEL A, LEVEL B, LEVEL C, AND LEVEL D SERVICE LIMITS

ND-3522 Stress and Pressure Limits

Level B, C, and D Service Limits are specified in Table ND-3521-1. The symbols used in Table ND-3521-1 are defined as follows:

σ_m	= general membrane stress, psi. This stress is equal to the average stress across the solid section under consideration. It excludes discontinuities and concentrations, and is produced only by pressure and other mechanical loads.
σ_L	= local membrane stress, psi. This stress is the same as σ_m , except that it includes the effect of discontinuities.
σ_b	= bending stress, psi. This stress is equal to the linear varying portion of the stress across the solid section under consideration. It excludes discontinuities and concentrations, and is produced only by pressure and other mechanical loads.
S	= allowable stress value given in Tables 1A and 1B, Section II, Part D, Subpart 1, psi. The allowable stress shall correspond to the highest metal temperature at the section under consideration during the loading under consideration.

Page 129

Page 130

FIG. ND-3521-1 TYPICAL SECTIONS OF VALVE BODIES

FIG. ND-3521-1 TYPICAL SECTION OF VALVE BODIES

ND-3530 GENERAL RULES

ND-3531 Hydrostatic Tests

The following requirements apply to valves designated to either ND-3512 or ND-3513.

ND-3531.1 Shell Hydrostatic Test.

A shell hydrostatic test shall be made using either water or air in accordance with the requirements of ANSI B16.34. Stem seal leakage during this test is permissible. Hydrostatic tests for metal bellows of metal diaphragm stem sealed valves shall include hydrostatic testing of the valve body, bonnet, body-to-bonnet joint, and either the bellows or diaphragm or the required backup stem seal. End closure seals for retaining fluid at test pressure in welding end valves may be positioned in the welding end transitions as defined in ANSI B16.34 in reasonable proximity to the end plane of the valve so as to ensure safe application of the test pressure.

ND-3531.2 Valve Closure Test.

After the shell hydrostatic test, a valve closure test shall be performed in accordance with ANSI B16.34 except that all valve sizes shall be subjected to a test differential pressure across the valve disk not less than 110% of the 100°F (38°C) pressure rating. During this test, seat leakage value is defined by the Design Specification.

ND-3531.3 Time at Pressure.

The duration of the shell hydrostatic test shall meet the requirements of ND-6223. The duration of the valve closure test shall be the greater of either 1 in./in. of minimum wall thickness t_m or the testing time requirement of ANSI B16.34, but not less than 1 min.

ND-3531.4 Exemptions to the Valve Closure Test

(a) For valves that are designed for Service Conditions that have the pressure differential across the closure member limited to values less than the 100°F (38°C) pressure rating, or that have closure members or actuating devices (direct, mechanical, fluid, or electrical) that would be subject to damage at high differential pressures, the test pressure may be reduced to 110% of the maximum specified differential pressure in the closed position. This exception shall be identified in the Design Specification, and this maximum specified differential pressure shall be noted on the valve name plate and the N Certificate Holder's Data Report Form.

(b) For valves designed for nonisolation service, the primary function of which is to modulate flow, and which by their design are prevented from providing full closure, the valve closure test defined in ND-3531.2 above is not required. This exception shall be identified in the Design Specification and noted on the valve nameplate and the N Certificate Holder's Data Report Form.

ND-3590 PRESSURE RELIEF VALVE DESIGN

ND-3591 Acceptability

ND-3591.1 General Requirements.

The rules of this Subsubarticle constitute the requirements for the design acceptability of spring-loaded pressure relief valves. The design rules for pilot operated and power actuated pressure relief valves are covered by ND-3500. The rules of this Subsubarticle cover the pressure retaining integrity of the valve inlet and outlet connections, nozzle, disk, body structure, bonnet (yoke), and body-to-bonnet (yoke) bolting. The rules of this Subsubarticle also cover other items such as the spring, spindle (stem), spring washers, and set pressure adjusting screw. The rules of this Subsubarticle do not apply to guides, control rings, bearings, set screws, and other nonpressure-retaining items. Figures ND-3591.1-1 and ND-3591.1-2 are illustrations of typical pressure relief valves.

ND-3591.2 Definitions.

The definitions for pressure relief valve terms used in this Subsubarticle are given in the American National Standard ANSI B95.1-1977, Terminology for Pressure Relief Devices, and also in ND-7000. Pressure relief valves characteristically have multipressure zones within the valve, that is, a primary pressure zone and a secondary pressure zone as illustrated by Figs. ND-3591.1-1 and ND-3591.1-2.

ND-3591.3 Acceptability of Small Pressure Relief Valves.

Pressure relief valves having inlet piping connections NPS 2 and under shall comply with the wall thickness requirements of ND-3595.1. Other elements of the valve shall be designed to ensure pressure integrity, in accordance with appropriate design practices based on successful experience in comparable service conditions.

ND-3591.4 Acceptability of Large Pressure Relief Valves.

The design shall be such that the requirements of this Subsubarticle are met.

ND-3592 Design Considerations

ND-3592.1 Design Conditions.

The general design requirements of ND-3100 are applicable with consideration for the design conditions of the primary and secondary pressure zones. In case of conflict between ND-3100 and ND-3590, the requirements of ND-3590

Page 131

Page 132

FIG. ND-3591.1-1 TYPICAL PRESSURE RELIEF DEVICES

shall apply. Mechanical loads for both the closed and open (full discharge) positions shall be considered in conjunction with the service conditions. In addition, the requirements of ND-7000 shall be met.

FIG. ND-3591.1-2 TYPICAL PRESSURE RELIEF DEVICES

FIG. ND-3591.1-2 TYPICAL PRESSURE RELIEF DEVICES

ND-3592.2 Stress Limits For Specified Service Loadings

(a) *Level A Service Loadings.* Stress limits for Level A service loadings for the valve shall be as follows.

(1) The general membrane stress shall not exceed S .

(2) The general membrane stress plus bending stress shall not exceed $1.5S$.

(3) Substantiation by analysis of localized stresses associated with contact loading of bearing or seating surfaces is not required.

(4) The values of S shall be in accordance with Tables 1A, 1B, and 3, Section II, Part D, Subpart 1.

(b) *Level B, C, and D Service Loadings.* Stress limits for Level B, C, and D service loadings are specified in Table ND-3592.2(b)-1. The symbols used in Table ND-3592.2(b)-1 are defined in ND-3522.

ND-3593 Special Rules

ND-3593.1 Hydrostatic Test.

Pressure relief valve shell hydrostatic tests shall be made in accordance with ND-3531.1 and ND-3531.3 except that the inlet (primary pressure containing) portion of the pressure relief valve shall be shell tested at a pressure at least equal to 1.5 times the set pressure marked on the valve. For closed system application, the outlet portion of the pressure relief valve shall be shell tested to 1.5 times the design secondary pressure (ND-7111).

ND-3593.2 Marking.

In addition to marking required by NCA-8220 and ND-7000, the secondary design pressure shall be marked on the valve or valve name plate.

ND-3594 Design Requirements for Level B, C, and D Service Loadings

(a) When the piping system in which the valve is located is designed to the requirements of ND-3600, the valve body may be considered adequate to withstand piping end loads, provided that conditions (1) and (2) below are satisfied.

(1) The section modulus and metal area at a plane normal to the flow passage through the region at the valve inlet and outlet (Figs. ND-3591.1-1 and ND-3591.1-2) shall be not less than 110% of the section modulus and metal area of the piping connected (or joined) to the valve inlet and outlet.

**TABLE ND-3592.2(b)-1
CLASS 3 PRESSURE RELIEF DEVICES:
LEVEL B, C, AND D SERVICE LOADINGS**

Service Loadings	Stress Limits
Level B	$\sigma_m \leq 1.1 S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.65 S$
Level C	$\sigma_m \leq 1.5 S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.8 S$
Level D	$\sigma_m \leq 2.0 S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 2.4 S$

GENERAL NOTES:

- (a) A casting quality factor is not required to satisfy these limits.
- (b) These requirements for the acceptability of valve design are not intended to ensure the functional adequacy of the valve. However, the designer is cautioned that the requirements of ND-7000 relative to set pressure, lift, blowdown, and closure shall be met.
- (c) Design requirements listed in this Table are applicable to those portions of the valves which are pressure retaining or affect pressure retaining items of these valves.

TABLE ND-3592.2(b)-1 CLASS 3 PRESSURE RELIEF DEVICES: LEVEL B, C, AND D SERVICE LOADINGS

(2) The allowable stress for valve body material shall be equal to or greater than the allowable stress of the connected piping material. If the valve body material allowable stress is less than that of the connected piping material, the valve section modulus and metal area shall be not less than 110% of the section modulus and metal area of the connecting pipe multiplied by the ratio $S_{\text{pipe}}/S_{\text{valve}}$.

(b) The pressure retaining portions of pressure relief valves shall conform to the stress limits listed in Table ND-3592.2(b)-1 for those service loadings stipulated as Level B, C, or D.

(c) Pressure relief valves have extended structures, and these structures are essential to maintaining pressure integrity. An

analysis, when required by the Design Specification, shall be performed based on static forces resulting from equivalent earthquake accelerations acting at the centers of gravity of the extended masses. Classical bending and direct stress equations, where free body diagrams determine a simple stress distribution that is in equilibrium with the applied loads, may be used.

ND-3595 Design of Pressure Relief Valve Parts

ND-3595.1 Body.

Minimum wall thicknesses of valve bodies shall conform to the applicable requirements for Standard Class category valves of ANSI B16.34, taking into account the dimensional and pressure conditions of the primary and secondary zones. Minimum wall thickness adjacent to the inlet nozzle and for a distance

Page 134

equal to that minimum wall thickness from the plane of the back face of the inlet flange shall be that required for Standard Class category valves of ANSI B16.34 for the inlet flange size and pressure class. Minimum wall thicknesses elsewhere in the secondary zone shall be determined by the requirements for Standard Class category valves of ANSI B16.34 for the outlet flange size and pressure class, including such other rules and considerations of ANSI B16.34 as may be applicable. In valve design where the outlet flange is an extension of the bonnet, the bonnet design shall conform to these rules. Where the inlet flange geometry involves inside contours encroaching on the metal section boundary represented by dimension B in Tables 9, 12, 15, 18, 21, 24, or 27 in ANSI B16.5, adequacy of the design shall be proven by stress calculation in accordance with ND-3658. Additional metal thickness needed for operating stresses, shapes other than circular, stress concentrations, and adequate structural strength of the crotch area(s) of the neck(s) of the valve for bending stresses and installation stress that may be imposed on the valve must be determined by the manufacturer.

ND-3595.2 Bonnet (Yoke).

The bonnet (yoke) may be analyzed using classic bending and direct stress formulae, with appropriate free body diagrams. The general membrane stress and the general membrane stress plus bending stress shall not exceed the stress limits of ND-3592.2.

ND-3595.3 Nozzle.

The minimum wall thickness of the nozzle shall be determined from the limit on general membrane stress. Alternatively, the rules of NB-3594.3 may be used. These requirements are not applicable to the transition region to the seat contacting area of the nozzle defined by L in Fig. ND-3595.3-1, provided the dimension L is less than the nominal wall thickness t .

ND-3595.4 Body-to-Bonnet Joint.

For valves having inlet piping connections NPS 2 and less, body-to-bonnet connections may be threaded. The thread shear stress, considering all loadings, shall not exceed 0.6 times the allowable stress S . The body-to-bonnet bolting shall be designed to resist the hydrostatic end force of the rated maximum secondary Design Pressure combined with the total spring load to full lift, and to maintain sufficient compression for a tight joint on the gasket or joint contact surface. The bolt stresses for these loadings shall not exceed the allowable stress values of Table 3, Section II, Part D, Subpart 1.

ND-3595.5 Disk.

The stress evaluation shall be made for the condition which results in the maximum stress in the disk. The bending stress shall not exceed the stress limits of ND-3592.2.

t = nozzle wall thickness, in.
 L = length of seal transition region, in.
 $L \leq t$

FIG. ND-3595.3-1 VALVE NOZZLE

FIG. ND-3595.3-1 VALVE NOZZLE

ND-3595.6 Spring Washer.

The shear stress shall not exceed 0.6S. The bending stress shall not exceed the stress limits of ND-3592.2.

ND-3595.7 Spindle (Stem).

The general membrane stress shall not exceed the stress limits of ND-3592.2.

ND-3595.8 Adjusting Screw.

The adjusting screw shall be analyzed for thread stress in accordance with the method of ANSI B1.1 and this stress shall not exceed 0.6S. The general membrane stress of the adjusting screw shall not exceed the stress limits of ND-3592.2, based on the root diameter of the thread.

ND-3595.9 Spring.

The valve spring shall be designed so that the full lift spring compression shall be no greater than 80% of the nominal solid deflection. The permanent set of the spring (defined as the difference between the free height and the height measured a minimum of 10 min after the spring has been

Page 135

compressed solid three additional times after presetting at room temperature) shall not exceed 1.0% of the free height.

ND-3596 Design Reports

ND-3596.1 General Requirements.

The manufacturer shall certify compliance with the requirements of this Subsubarticle in accordance with the provisions of NCA-3570.

ND-3600 PIPING DESIGN

ND-3610 GENERAL REQUIREMENTS

ND-3611 Acceptability

The requirements for acceptability of a piping system are given in the following subparagraphs.

[98]

ND-3611.1 Allowable Stress Values.

Allowable stress values to be used for the design of piping systems are given in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1.

[98]

[98]

ND-3611.2 Stress Limits

(a) *Design and Service.* Loadings shall be specified in the Design Specification.

(b) *Design Loadings.* The sum of stresses due to design internal pressure, weight, and other sustained loads shall meet the requirements of Eq. (8), ND-3652.

(c) *Service Loadings.* The following Service Limits shall apply to Service Loadings as designated in the Design Specification.

(1) *Level A and B Service Limits.* For Service Loadings for which Level A and B Service Limits are designated in the Design Specification, the requirements of ND-3653 shall be met. When Level B Limits apply, the peak pressure $P_{\max}$ alone shall not exceed 1.1 times the pressure P_a calculated in accordance with Eq. (5), ND-3641.1.

(2) *Level C Service Limits.* For Service Loadings for which Level C Service Limits are designated in the Design Specification, the sum of stresses shall meet the requirements of ND-3654.

(3) *Level D Service Limits.* For Service Loadings for which Level D Service Limits are designated in the Design Specification, the sum of stresses due to internal pressure, live and dead load, and those due to occasional loads shall meet the requirements of ND-3655.

(4) *Test Conditions.* Testing shall be in accordance with ND-6000. Occasional loads shall not be considered as acting at time of test.

(d) *External Pressure Stress.* Piping subject to external pressure shall meet the requirements of ND-3641.2.

(e) *Allowable Stress Range for Expansion Stresses.* The allowable stress range S_A is given by Eq. (1):

$$(1) S_A = f(1.25 S_c + 0.25 S_h)$$

where

S_c = basic material allowable stress at minimum (cold) temperature, psi

S_h = basic material allowable stress at maximum (hot) temperature, psi

f = stress range reduction factor for cyclic conditions for total number N of full temperature cycles over total number of years during which system is expected to be in service, from Table ND-3611.2(e)-1

(1) In determining the basic material allowable stresses S_c and S_h , joint efficiencies need not be applied.

(2) Stress reduction factors apply essentially to noncorrosive service and to corrosion resistant materials, where employed to minimize the reduction in cyclic life caused by corrosive action.

(3) If the range of temperature change varies, equivalent full temperature cycles may be computed as follows:

$$(2) N = N_E + r_1^5 N_1 + r_2^5 N_2 + \dots + r_n^5 N_n$$

where

N_E = number of cycles at full temperature change ΔT_E for which expansion stress S_E has been calculated

$N_1, N_2, \dots, N_n$ = number of cycles at lesser temperature changes, $\Delta T_1, \Delta T_2, \dots, \Delta T_n$

$r_1, r_2, \dots, r_n$ = $(\Delta T_1)/(\Delta T_E), (\Delta T_2)/(\Delta T_E), \dots, (\Delta T_n)/(\Delta T_E)$

= the ratio of any lesser temperature cycles for which the expansion stress S_E has been calculated

(f) *Allowable Stress for Nonrepeated Stresses.* The allowable stress due to any single nonrepeated anchor movement (such as predicted building settlement) calculated in accordance with Eq. (10a) of ND-3653.2(b) shall be $3.0S_c$.

[98]

**TABLE ND-3611.2(e)-1
STRESS RANGE REDUCTION FACTORS**

Number of Equivalent Full Temperature Cycles <i>N</i>	<i>f</i>
7,000 and less	1.0
7,000 to 14,000	0.9
14,000 to 22,000	0.8
22,000 to 45,000	0.7
45,000 to 100,000	0.6
100,000 and over	0.5

TABLE ND-3611.2(e)-1 STRESS RANGE REDUCTION FACTORS

ND-3612 Pressure-Temperature Ratings for Piping Products

ND-3612.1 Piping Products Having Specific Ratings

(a) Pressure-temperature ratings for certain piping products have been established and are contained in some of the standards listed in Table ND-3132-1. The pressure ratings at the corresponding temperatures given in the standards listed in Table ND-3132-1 shall not be exceeded, and piping products shall not be used at temperatures in excess of those given in Tables 1A and 1B Section II, Part D, Subpart 1 for the materials of which the products are made.

(b) Where piping products have established pressure-temperature ratings which do not extend to the upper material temperature limits permitted by this Subsection, the pressure-temperature ratings between those established and the upper material temperature limit may be determined in accordance with the rules of this Subsection.

ND-3612.2 Piping Products Not Having Specific Ratings.

Should it be desired to use methods of manufacture or design of piping products not covered by this Subsection, it is intended that the manufacturer shall comply with the requirements of ND-3640 and ND-3690 and other applicable requirements of this Subsection for the Design Loadings involved. The manufacturer's recommended pressure ratings shall not be exceeded.

ND-3612.4 Considerations for Local Conditions and Transients

(a) Where piping systems operating at different pressures are connected by a valve or valves, the valve or valves shall

be designed for the higher pressure system requirements of pressure and temperature. The lower pressure system shall be designed in accordance with (1), (2), or (3) below.

(1) The requirements of the higher pressure system shall be met.

(2) Pressure relief devices or safety valves shall be included to protect the lower pressure system in accordance with ND-7311 and ND-7321.

(3) Assure compliance with all the conditions of (a) through (e) below.

(a) Redundant check or remote actuated valves shall be used in series at the interconnection, or a check in series with a remote actuated valve.

(b) When mechanical or electrical controls are provided, redundant and diverse controls shall be installed which will prevent the interconnecting valves from opening when the pressure in the high pressure system exceeds the Design Pressure of the low pressure system.

(c) Means shall be provided such that operability of all components, controls, and interlocks can be verified by test.

(d) Means shall be provided to assure that the leakage rate of the interconnecting valves does not exceed the relieving capacity of the relief devices on the low pressure system.

(e) Adequate consideration shall be given to the control of fluid pressure caused by heating of the fluid trapped between two valves.

The low pressure system relieving capacity may be determined in accordance with ND-7311 and ND-7321, on the basis of the interconnecting valve being closed but leaking at a specified rate, when (a) through (e) above are met. The pressure relief devices or safety valves shall adjoin or be as close as possible to the interconnecting valve and shall relieve preferably to a system where the relieved effluent may be contained. The design of the overpressure protection system shall be based on pressure transients that are specified in the Design Specification, and all other applicable requirements of ND-7000 shall be met.

(b) Where pressure reducing valves are used and one or more pressure relief devices or safety valves are provided, bypass valves may be provided around the pressure reducing valves. The combined relieving capacity of the pressure relief devices, safety valves, and relief piping shall be such that the lower pressure system service pressure will not exceed the lower pressure system Design Pressure by more than 10% if the pressure reducing valve fails in the open position and the bypass valve is open at the same time. If the pressure reducing valve and its bypass valve are mechanically or electrically interlocked so that only one may be open at any time, the high pressure system is at a pressure higher than the Design Pressure of the

Page 137

low pressure system, the relieving capacity of the pressure relief devices, safety valves, and relief piping shall be at least equal to the maximum capacity of the larger of the two valves. The interlocks shall be redundant and diverse.

(c) Exhaust and pump suction lines for any service and pressure shall have relief valves of a suitable size, unless the lines and attached equipment are designed for the maximum pressure and temperature to which they may be accidentally or otherwise subjected.

(d) The effluent from relief devices may be discharged outside the containment only if provisions are made for the disposal of the effluent.

(e) Drip lines from steam headers, mains, separators, or other equipment operating at different pressures shall not discharge through the same trap. Where several traps discharge into a single header that is or may be under pressure, a stop valve and a check valve shall be provided in the discharge line from each trap. The Design Pressure of trap discharge piping shall not be less than the maximum discharge pressure to which it may be subjected. Trap discharge piping shall be designed for the same pressure as the trap inlet piping, unless the discharge piping is vented to a system operated under lower pressure and has no intervening stop valves.

(f) Blowdown, dump, and drain piping from water spaces of a steam generation system shall be designed for saturated steam at the pressures and temperatures given below.

Vessel Pressure, psi	Design Pressure, psi	Design Temperature, °F
600 and below	250	410
601 to 900	400	450
901 to 1500	600	490
1501 and above	900	535

These requirements for blowdown, dump, and drain piping apply to the entire system beyond the blowdown valves to the blowdown tank or other points where the pressure is reduced to approximately atmospheric and cannot be increased by closing a valve. Where pressures can be increased because of calculated pressure drop or otherwise, this shall be taken into account in the design. Such piping shall be designed for the maximum pressure to which it may be subjected.

(g) Pump discharge piping shall be designed for the maximum pressure exerted by the pump at any load and for the highest corresponding temperature actually existing.

**TABLE ND-3613.4-1
WELD JOINT EFFICIENCY FACTOR**

Type of Longitudinal Joint	Weld Joint Efficiency Factor <i>E</i>
Arc Weld	
Single butt weld	0.80
Double butt weld	0.90
Single or double butt weld with 100% radiography per ND-2560 for joints welded with filler metal or otherwise examined by ultrasonic methods per ND-2550 for joints welded without filler metal, as applicable	1.00
Electric resistance weld	0.85

TABLE ND-3613.4-1 WELD JOINT EFFICIENCY FACTOR

(h) When a fluid passes through heat exchangers in series, the Design Temperature of the piping in each section of the system shall conform to the most severe temperature condition expected to be produced by heat exchangers in that section.

ND-3613 Allowances

ND-3613.1 Corrosion or Erosion.

When corrosion or erosion is expected, the wall thickness of the piping shall be increased over that required by other design requirements. This allowance shall be consistent with the specified design life of the piping.

ND-3613.2 Threading and Grooving.

The calculated minimum thickness of piping that is to be threaded or grooved shall be increased by an allowance equal to the depth of the cut.

ND-3613.3 Mechanical Strength.

When necessary to prevent damage, collapse, or buckling of pipe due to superimposed loads from supports or other causes, the wall thickness of the pipe shall be increased, or, if this is impractical or would cause excessive local stresses, the superimposed loads or other causes shall be reduced or eliminated by other design methods.

ND-3613.4 Pressure Design Weld Joint Efficiency for Butt Welds.

Longitudinal weld joint efficiency factors for pressure design for butt welds as listed in Table ND-3613.4-1 shall be applied to the allowable stress values given in Tables 1A and 1B, Section II, Part D, Subpart 1.

ND-3613.5 Steel Casting Quality Factors.

The quality factors for castings required in Tables 1A and 1B,

Page 138

Section II, Part D, Subpart 1 apply to castings which are designed using the stresses contained in this Subsection. The minimum examination required for these castings is that stipulated in the applicable material specification and in ND-2570. Castings satisfying these minimum requirements shall be designed with a quality factor of 1.00.

ND-3620 DESIGN CONSIDERATIONS

ND-3621 Design and Service Loadings

The provisions of ND-3110 shall apply, except as modified in this Subarticle.

ND-3621.1 Cooling Effects on Pressure.

When the cooling of a fluid may reduce the pressure in the piping to below atmospheric, the piping shall be designed to withstand the external pressure or provision shall be made to break the vacuum.

ND-3621.2 Fluid Expansion Effects.

When the expansion of a fluid may increase the pressure, the piping system shall be designed to withstand the increased pressure or provision shall be made to relieve the excess pressure.

ND-3622 Dynamic Effects

ND-3622.1 Impact.

Impact forces caused by either external or internal loads shall be considered in the piping design.

ND-3622.2 Reversing Dynamic Loads.

Reversing dynamic loads are those loads which cycle about a mean value and include building filtered loads, earthquake, and the reflected waves in a piping system due to flow transients resulting from sudden opening or closure of valves (see Fig. ND-3622-1). A reversing dynamic load shall be treated as a nonreversing dynamic load in applying the rules of ND-3600 when either of the following conditions exist:

- (a) The frequency ratio of the dynamic dominant load driving frequency to the lowest piping system natural frequency is less than 0.5.
- (b) The number of reversing dynamic load cycles, exclusive of earthquake, exceed 20.

ND-3622.3 Vibration.

Piping shall be arranged and supported so that vibration will be minimized. The designer shall be responsible, by design and by observation under startup or initial service conditions, for ensuring that vibration of piping systems is within acceptable levels.

ND-3622.4 Exposed Piping.

Exposed piping shall be designed to withstand wind loadings, using meteorological data to determine wind forces. When State, Province, or Municipal ordinances covering the design of building structures are in effect and specify wind loadings, these values shall be considered the minimum design values. However, it is not necessary to consider earthquake and wind loadings to be acting concurrently.

ND-3622.5 Nonreversing Dynamic Loads.

Nonreversing dynamic loads are those loads which do not cycle about a mean value and include the initial thrust force due to sudden opening or closure of valves and waterhammer resulting from entrapped water in two-phase flow systems (see Fig. ND-3622-1).

ND-3623 Weight Effects

Piping systems shall be supported to provide for the effects of live and dead weights, as defined in the following subparagraphs, and they shall be arranged or properly restrained to prevent undue strains on equipment.

ND-3623.1 Live Weight.

The live weight shall consist of the weight of the fluid being handled or of the fluid used for testing or cleaning, whichever is greater.

ND-3623.2 Dead Weight.

The dead weight shall consist of the weight of the piping, insulation, and other loads permanently imposed upon the piping.

ND-3624 Thermal Expansion and Contraction Loads

ND-3624.1 General Requirements

- (a) The design of piping systems shall take account of the forces and moments resulting from thermal expansion and contraction and from the effects of expansion joints.
- (b) Thermal expansion and contraction shall be provided for, preferably by pipe bends, elbows, offsets, or changes in direction of the piping.
- (c) Hangers and supports shall permit expansion and contraction of the piping between anchors.

ND-3624.2 Expansion Joints.

Expansion joints of the corrugated, slip sleeve, ball, or swivel types may be used if they conform to the requirements of ND-3649.1 through ND-3649.4, their structural and working parts are designed for the maximum pressure and temperature of the piping system, and their design prevents the complete disengagement of working parts while in service.

FIG. ND-3622-1 EXAMPLES OF REVERSING AND NONREVERSING DYNAMIC LOADS

ND-3640 PRESSURE DESIGN OF PIPING PRODUCTS

ND-3641 Straight Pipe

[98]

ND-3641.1 Straight Pipe Under Internal Pressure.

The minimum thickness of pipe wall required for Design Pressures and for temperatures not exceeding those for the various materials listed in Tables 1A and 1B, Section II, Part D, Subpart 1, including allowances for mechanical strength, shall not be less than that determined by Eq. (3) as follows:

$$t_m = \frac{PD_o}{2(SE + Py)} + A \quad (3)$$

$$t_m = \frac{Pd + 2SEA + 2yPA}{2(SE + Py - P)} \quad (4)$$

(3 - 4)

where

t_m

= minimum required wall thickness, in. If pipe is ordered by its nominal wall thickness, the manufacturing tolerance on wall thickness must be taken into account. After the minimum pipe wall thickness t_m is determined by Eq. (4), this minimum thickness shall be increased by an amount sufficient to provide the manufacturing tolerance allowed in the applicable pipe specification or required by the process. The next heavier commercial wall thickness shall then be selected from standard thickness schedules such as contained in ANSI B36.10 or from manufacturers' schedules for other than standard thickness.

P

= internal Design Pressure, psi

D_o

= outside diameter of pipe, in. For design calculations, the outside diameter of pipe as given in tables of standards and specifications shall be used in obtaining the value of t_m . When calculating the allowable pressure of pipe on hand or in stock,

the actual measured outside diameter and actual measured minimum wall thickness at the thinner end of the pipe may be used to calculate this pressure.

d

= inside diameter of pipe, in. In using Eq.(4) the value of d is for the maximum possible inside diameter allowable under the purchase specification.

S

= maximum allowable stress for the material at the Design Temperature, psi (Section II, Part D, Subpart 1, Tables 1A and 1B)

E

= joint efficiency for the type of longitudinal joint used, as given in Table ND-3613.4-1, or casting quality factor determined in accordance with ND-3613.5

A

= additional thickness, in.:

(a) to compensate for material removed or wall thinning due to threading or grooving, required to make a mechanical joint. The values of A listed in Table ND-3641.1(a)-1 are minimum values for material removed in threading.

(b) to provide for mechanical strength of the pipe. Small diameter, thin wall pipe or tubing is susceptible to mechanical damage due to erection, operation, and maintenance procedures. Accordingly, appropriate means must be employed to protect such piping against these types of loads if they are not considered as Design Loads. Increased wall thickness is one way of contributing to resistance against mechanical damage.

(c) to provide for corrosion or erosion. Since corrosion and erosion vary widely from installation to installation, it is the responsibility of designers to determine the proper amounts which must be added for either or both of these conditions.

**TABLE ND-3641.1(a)-1
VALUES OF A**

Type of Pipe	A , in.
Threaded steel and nonferrous pipe: 3/4 in. nominal and smaller	0.065
1 in. nominal and larger	Depth of thread
Grooved steel and nonferrous pipe	Depth of groove plus 1/64 in.

TABLE ND-3641.1(a)-1 VALUES OF A

The allowable working pressure of pipe may be determined from the following equation:

$$P_a = \frac{2SEt}{D_o - 2yt} \quad (5)$$

(5)

where

t	= the specified or actual wall thickness minus, as appropriate, material removed in threading, corrosion or erosion allowance, material manufacturing tolerances, bending allowance (NB-3642.1), material to be removed by counterboring, in.
P_a	= the calculated maximum allowable internal pressure, psi, for straight pipe which shall at least equal the Design Pressure. P_a may be used for piping products with pressure ratings equal to that of straight pipe (see ANSI B16.9). For standard flanged joints, the rated pressure shall be used instead of P_a . For other piping products where the pressure rating may be less than that of the pipe [for example, flanged joints designed to Appendix XI and reinforced branch connections (ND-3643) where part of the required reinforcement is in the run pipe], the Design Pressure shall be used instead of P_a . P_a may be rounded out to the next higher unit of 10.
y	= a coefficient having a value of 0.4, except that for pipe with a D_o/t_m ratio less than 6, the value of y shall be taken as:

$$y = \frac{d}{d + D_o} \quad (6)$$

(6)
[98]

ND-3641.2 Straight Pipe Under External Pressure.

For determining wall thickness and stiffening requirements for straight pipe under external pressure, the procedures outlined in ND-3133 shall be followed.

ND-3642 Curved Segments of Pipe

ND-3642.1 Pipe Bends.

Pipe bends shall be subject to the limitations in (a), (b), and (c) below.

(a) The minimum wall thickness after bending shall not be less than the minimum wall thickness required for straight pipe.

(b) The ovality shall meet the requirements of ND-4223.2.

(c) The information in Table ND-3642.1(c)-1 is given to guide the designer when ordering pipe.²⁰

²⁰ The minimum thicknesses of straight pipe shown in Table nd-3642.1(c)-1 should be sufficient to allow the pipe to meet the minimum wall thicknesses requirements of ND-3641 after having been

**TABLE ND-3642.1(c)-1
MINIMUM THICKNESS FOR BENDING**

Radius of Bends	Minimum Thickness Recommended Prior to Bending [Note (1)]
6 pipe diameters or greater	$1.06t_m$
5 pipe diameters	$1.08t_m$
4 pipe diameters	$1.16t_m$
3 pipe diameters	$1.25t_m$

NOTE:

(1) t_m is determined by Eq. (3) or (4) of ND-3641.1.

TABLE ND-3642.1(c)-1 MINIMUM THICKNESS FOR BENDING

ND-3642.2 Elbows.

Flanged elbows manufactured in accordance with the standards listed in Table ND-3132-1 shall be considered suitable for use at the pressure-temperature ratings specified by such standards. In the case of standards under which butt welding elbows are made to a nominal wall thickness, the elbows shall be considered suitable for use with pipe of the same nominal thickness and of the same material.

ND-3643 Intersections

[98]

ND-3643.1 General Requirements

(a) ND-3643 gives acceptable rules governing the design of branch connections to sustain internal and external pressure in cases where the axes of the branch and the run intersect, the angle between the axes of the branch and of the run is between 45 deg and 90 deg, inclusive, and no allowance is required for corrosion or erosion.

(b) Branch connections in which the smaller angle between the axes of the branch and the run is less than 45 deg impose special design and fabrication problems. The rules given for angles between 45 deg and 90 deg, inclusive, may be used as a guide, but sufficient additional strength must be provided to assure safe service. Such branch connections shall be designed to meet the requirements of ND-3649.

(c) Branch connections in piping may be made by using one of the products or methods given in (1) through (4) below:

(1) flanged, butt welding, socket welding, or screwed fittings made in accordance with the applicable standards listed in Table ND-3132-1;

(2) welding outlet fittings, such as cast or forged nozzles; couplings including ANSI B16.11 couplings, to a maximum nominal size of 3 in.; and adaptors or similar items having butt welding, socket welding, threaded, or flanged ends for attachment of the branch

Page 142

pipe. Such outlet fittings shall be attached to the main pipe:

(a) by the full penetration weld; or

(b) for right angle branch connections, by a fillet weld or partial penetration weld as shown in Fig. ND-3643.2(b)-2, sketch (e) or (f), provided the requirements of (1) through (4), as follows, are met:

(1) the nominal size of the branch shall not exceed 2 in. or one-quarter of the nominal size of the run, whichever is less;

(2) the minimum size of the weld, $x_{\min}$, shall not be less than $1\frac{1}{4}$ times the fitting wall thickness in the reinforcement zone;

(3) the groove angle, θ , shall be equal to or greater than 45 deg;

(4) except for attaching ANSI B16.11 couplings, the requirements of ND-3643.3 shall be met.

(3) extruded outlets at right angles to the run pipe, in accordance with ND-3643.4, where the attachment of the branch pipe is by butt welding;

(4) by attaching the branch pipe directly to the run pipe by welding or threading as stipulated in (a), (b), or (c) below:

(a) right angle branch connections may be made by attaching the branch pipe to the run pipe by socket welding, provided the requirements of (1) through (5) below are met:

(1) the nominal size of branch does not exceed 2 in. (51 mm) or one-fourth the nominal size of the run, whichever is less;

(2) the depth of the socket in the run is at least equal to that shown in ANSI B16.11 with a minimum shoulder of $\frac{1}{16}$ in. (1.6 mm) between the bottom of the socket and the inside diameter of the run pipe; weld metal may be deposited on the run pipe to provide the required socket depth and to provide any reinforcement required;

(3) a minimum of $\frac{1}{16}$ in. (1.6 mm) clearance shall be provided between the bottom of the socket and the end of the inserted pipe;

(4) the size of the fillet weld shall not be less than $1\frac{1}{4}$ times the nominal branch wall thickness;

(5) the requirements of ND-3643.3 shall be met.

(b) right angle branch connections may be made by attaching the branch pipe directly to the run by threading within the provisions of ND-3671.3 and provided the requirements of (1) and (2) below are met:

(1) the nominal size of the branch does not exceed 2 in. or one-fourth the nominal size of the run, whichever is less;

(2) minimum thread engagement shall be six full threads for $\frac{1}{2}$ in. and $\frac{3}{4}$ in. (DN 15 and DN 20) branches; seven for 1 in., $1\frac{1}{4}$ in. and $1\frac{1}{2}$ in. (DN 15, DN 32, and DN 40) branches; and eight for 2 in. branches; weld metal may be deposited on the run pipe to provide sufficient thickness for required thread engagement;

(5) branch connections may be made by attaching the branch pipe directly to the run pipe:

(a) by a full penetration weld as shown in Fig. ND-3643.2(b)-1, with or without pad or saddle reinforcement as shown in Fig. ND-3643.3(c)(1)-1 or Fig. ND-3643.3(c)(1)-2, provided the requirements of ND-3643.3 are met; or

(b) for right angle branch connections, by a fillet weld or partial penetration weld as shown in Fig. ND-3643.2(b)-2,

sketches (a) through (d), provided the requirements of (1) through (4), as follows, are met:

- (1) the nominal size of the branch shall not exceed 2 in. (DN 50) or one-quarter of the nominal size of the run, whichever is less;
- (2) the minimum size of the weld, $x_{\min}$, shall not be less than $1\frac{1}{4}$ times the nominal branch wall thickness;
- (3) the groove angle, θ , shall be equal to or greater than 45 deg;
- (4) the requirements of ND-3643.3 shall be met.

[98]

ND-3643.2 Branch Connections Not Requiring Reinforcement.

Reinforcement need not be provided if the branch connection is made in accordance with the requirements of (a) through (c) below:

(a) by the use of a fitting manufactured in accordance with one of the standards listed in Table ND-3132-1 and used within the limits of pressure-temperature ratings specified in such standards, a butt welding fitting made in accordance with ANSI B16.9 shall be of nominal thickness not less than the nominal thickness required for the adjoining pipe;

(b) by welding a coupling or half coupling directly to the run pipe, provided the nominal diameter of the branch does not exceed 2 in. pipe size (DN 50) or one-fourth the nominal diameter of the run, whichever is less; the wall thickness of the coupling is not less than that of the branch pipe; the coupling is joined to the run pipe by one of the methods shown in Fig. ND-3643.2(b)-1 sketch (c)(1) or Fig. ND-3643.2(b)-2 sketch (e); and in no case is the thickness of the coupling less than extra heavy or 3000 lb nominal rating;

(c) by using an extruded outlet, provided the nominal diameter of the branch does not exceed 2 in. pipe size (DN 50) or one-fourth the nominal diameter of the pipe, whichever is less, and the minimum wall thickness

Page 143

at the abutting end of the outlet is not less than required for the branch pipe wall.

(b) Typical Welded Angular Branch Connection Without Additional Reinforcement

(c) Typical Branch Connections Made Using a Full Penetration Weld

FIG. ND-3643.2(b)-1 TYPICAL WELDED BRANCH CONNECTIONS

FIG. ND-3643.2(b)-1 TYPICAL WELDED BRANCH CONNECTIONS

ND-3643.3 Branch Connections Requiring Reinforcement

(a) Calculations shall be made to determine the adequacy of reinforcement in branch connections except as exempted in ND-3643.2.

(b) A branch connection may be made by extruding an integrally reinforced outlet on the run pipe. The reinforcement requirements shall be in accordance with ND-3643.4.

(c) A branch connection may be made by welding a pipe or fitting directly to the run pipe with or without added reinforcement, provided the pipe or fitting, deposited weldment, and other reinforcing devices meet the requirements of this subparagraph. This subparagraph gives rules covering the design of branch connections to sustain internal pressure in cases where the angle between the axes of the branch and of the run ranges from 45 deg to 90 deg. ND-3643.5 gives rules governing the design of connections to sustain external pressure.

(1) *Nomenclature.* Figures ND-3643.3(c)(1)-1 and ND-3643.3(c)(1)-2 illustrate the notations used in the pressure-temperature design conditions of branch connections, which are as follows:

α	= angle between axes of branch and run, deg
b	= subscript referring to branch
D_o	= outside diameter of pipe, in.
d_1	= inside diameter of branch for right angle connections, in.; for connections at angles between 45 deg and 90 deg, $d_1 = (D_{ob} - 2T_b)/\sin \alpha$
d_2	= half width of reinforcing zone, in. = the greater of d_1 or $T_b + T_h + (d_1/2)$ but in no case more than D_{ob}
h	= subscript referring to run or header
L	= height of reinforcement zone outside of run or reinforcement, in. = $2.5T_b$
t_e	= thickness of attached reinforcing pad or height of the largest 60 deg right triangle supported by the run and branch outside diameter projected surfaces and lying completely within the area of integral reinforcement, in. [Fig. ND-3643.3(c)(1)-2]
T	= nominal, actual by measurement, or minimum wall thickness of pipe, in., permissible under purchase specification
t_m	= required minimum wall thickness, in., of pipe for pressure and temperature design conditions as determined by use of Eq. (3) or (4), ND-3641.1

T_b = Nominal branch pipe wall thickness
 $X_{min} = 1\frac{1}{4} T_b$
 θ = Partial penetration weld groove angle ≥ 45 deg

ANSI B16.11 Coupling

(e)

Welded Outlet Fitting

(f)

T_b = Fitting wall thickness in the reinforcement zone
 (when the fitting is tapered in the reinforcement zone, use average wall thickness)
 $X_{min} = 1\frac{1}{4} T_b$
 θ = Partial penetration weld groove angle ≥ 45 deg

FIG. ND-3643.2(b)-2 TYPICAL RIGHT ANGLE BRANCH CONNECTIONS MADE USING A FILLET WELD OR A PARTIAL PENETRATION WELD

FIG. ND-3643.2(b)-2 TYPICAL RIGHT ANGLE BRANCH CONNECTIONS MADE USING A FILLET WELD OR A PARTIAL PENETRATION WELD

FIG. ND-3643.3(c)(1)-2 SOME REPRESENTATIVE CONFIGURATIONS DESCRIBING THE t_e REINFORCEMENT DIMENSION

FIG. ND-3643.3(c)(1)-2 SOME REPRESENTATIVE CONFIGURATIONS DESCRIBING THE t_e REINFORCEMENT DIMENSION

(2) *Requirements.* A pipe having a branch connection is weakened by the opening that must be made in it and, unless the wall thickness of the pipe is sufficiently in excess of that required to sustain the pressure, it is necessary to provide additional reinforcement. The amount of reinforcement required shall be determined in accordance with ND-3643.3(c)(3) through (c)(7), ND-3643.4, or ND-3643.5.

(3) *Reinforcement Area.* The required reinforcement area in sq in. for branch connections shall be the quantity $1.07(t)(d)(2 - \sin \alpha)$.

(a) For right angle connections, the required reinforcement becomes $1.07(t_{mh})(d_1)$.

(b) The required reinforcement must be within the limits of the reinforcement zone as defined in ND-3643.3(c)(5).

(4) *Area Contributing to Reinforcement.* Metal needed to meet reinforcement required by ND-3643.3(c) must be within the limits of reinforcement zone determined in ND-3643.3(c)(5) and may include the following.

A_1 = area provided by excess pipe wall in the run, sq in.

$$= (2d_2 - d_1) [(T_h - \text{mill tolerance on } T_h) - t_{mh}]$$

A_2 = area provided by excess pipe wall in the branch for a distance L above the run, sq in.

$= 2L/\sin \alpha [(T_b - \text{mill tolerance on } T_b) - t_{mb}]$. In areas A_1 and A_2 , mill tolerance becomes zero when the minimum wall is specified instead of nominal wall.

A_3 = area provided by deposited weld metal beyond the outside diameter of the run and branch, sq in.

A_4 = area provided by reinforcement, sq in.

When the reinforcement area is composed of material with lower allowable stress than that of the run pipe, such reinforcement areas shall be increased by the inverse ratio of allowable stresses. No adjustment shall be made in reinforcement area for use of materials that have higher allowable stresses than the materials of the run pipe. Such reinforcement areas shall be decreased by the ratio of allowable stresses prior to any combination of areas to meet the reinforcement requirements of ND-3643.3(c).

(5) *Reinforcement Zone.* The reinforcement zone is a parallelogram, the length of which shall extend a distance d_2 on each side of the center line of the branch pipe and the width of which shall start at the inside surface of the run pipe and extend to a distance $(L + t_e)$ or $2.5T_p$ whichever is less, from the outside surface of the run pipe, when measured in the plane of the branch connection.

(6) *Reinforcement of Multiple Openings*

(a) When any two or more adjacent openings are so closely spaced that their reinforcement zones overlap, the two or more openings shall be reinforced in accordance with ND-3643.3(c)(3) with a combined reinforcement that has a strength equal to the combined strength of the reinforcement which would be required for the separate openings. No portion of the cross section shall be considered as applying to more than one opening or be evaluated more than once in a combined area.

(b) When more than two adjacent openings are to be provided with a combined reinforcement, the minimum distance between centers of any two of these openings should preferably be at least $1\frac{1}{2}$ times their average diameter and the area of reinforcement between them shall be at least equal to 50% of the total required for these two openings.

(7) *Rings, Pads, and Saddles*

(a) Reinforcement provided in the form of rings, pads, or saddles shall not be appreciably narrower at the side than at the crotch.

(b) A vent hole shall be provided at the ring, pad, or saddle to provide venting during welding and heat treatment.

(c) Rings, pads, or saddles may be made in more than one piece, provided the joints between pieces have full thickness welds and each piece is provided with a vent hole.

(d) Where saddles or pads are being employed for reinforcement, the potential for increased strain at the attachment welds which may occur as a result of rapid changes in differential metal temperatures between the saddle or pad and the run should be considered in the design evaluation.

ND-3643.4 Special Requirements for Extruded Outlets.

The definitions, limitations, nomenclature, and requirements of (a) through (h) below are specifically applicable to extruded outlets.

(a) *Definition.* An extruded outlet header is a header in which the extruded lip at the outlet has a height above the surface of the run which is equal to or greater than the radius of the curvature of the external contoured portion of the outlet $h_o \geq r_o$ [Fig. ND-3643.4(a)-1].

(b) *Cases to Which Rules Are Applicable.* These rules apply only to cases where the axis of the outlet intersects and is perpendicular to the axis of the run.

(c) *Nomenclature.* The notation used herein is illustrated in Fig. ND-3643.4(a)-1.

d	= outside diameter of branch pipe, in.
d_c	= corroded internal diameter of branch pipe, in.
D	= outside diameter of run, in.

Page 148

Page 149

D_c	= corroded internal diameter of run, in.
D_o	= corroded internal diameter of extruded outlet measured at the level of the outside surface of the run, in.
h_o	= height of the extruded lip, in.; this must be equal to or greater than r_o except as permitted in ND-3643.4(d)(4)
L	= height of reinforcement zone, in. $= 0.7 \sqrt{dT_o}$
t_b	= required thickness of branch pipe according to wall thickness Eq. (3) or (4), ND-3641.1, not including any thickness for corrosion, in.
T_b	= actual thickness of branch wall, not including the corrosion allowance, in.
t_r	= required thickness of the run according to Eq. (3) or (4), ND-3641.1, not including any allowance for corrosion, in.
T_r	= actual thickness of run wall, not including the corrosion allowance, in.
T_o	= corroded finished thickness of extruded outlet measured at a height equal to r_o above the outside surface of the run, in.
r_l	= half width of reinforcement zone, in. $= D_o$
r_o	= radius of curvature of external contoured portion of outlet measured in the plane containing the axes of the run and branch, in.; this is subject to the limitations given in (d) below

T_b = Nominal branch pipe wall thickness
 $X_{min} = 1\frac{1}{4} T_b$
 θ = Partial penetration weld groove angle ≥ 45 deg

ANSI B16.11 Coupling

Welded Outlet Fitting

T_b = Fitting wall thickness in the reinforcement zone
 (when the fitting is tapered in the reinforcement zone, use average wall thickness)
 $X_{min} = 1\frac{1}{4} T_b$
 θ = Partial penetration weld groove angle ≥ 45 deg

FIG. ND-3643.2(b)-2 TYPICAL RIGHT ANGLE BRANCH CONNECTIONS MADE USING A FILLET WELD OR A PARTIAL PENETRATION WELD

FIG. ND-3643.4(a)-1 REINFORCED EXTRUDED OUTLETS

(d) Radii

(1) The minimum radius shall not be less than $0.05d$, except that on branch diameters larger than 30 in. it need not exceed $1\frac{1}{2}$ in. (38 mm).

(2) The maximum radius for outlet pipe sizes 6 in. nominal (DN 150) and larger shall not exceed $0.10d + 0.50$ in. For outlet pipe sizes less than 6 in. nominal (DN 150), this dimension shall be not greater than $1\frac{1}{4}$ in. (32 mm).

(3) When the external contour contains more than one radius, the radius of any arc sector of approximately 45 deg

shall meet the requirements of (1) and (2) above.

(4) Machining shall not be employed in order to meet the above requirements.

(e) *Required Area*. The required area is defined as:

$$A = K(t_r)(D_o)$$

where K shall be taken as follows:

(1) for d/D greater than 0.60, $K = 1.00$

(2) for d/D greater than 0.15 and not exceeding 0.60, $K = 0.6 + 2d/3D$

(3) for d/D equal to or less than 0.15, $K = 0.70$

(f) *Reinforcement Area*. The reinforcement area shall be the sum of areas $A_1 + A_2 + A_3$ as defined in (1), (2), and (3) below.

(1) Area A_1 is the area lying within the reinforcement zone resulting from any excess thickness available in the run wall:

$$A_1 = D_o(T_r - t_r)$$

(2) Area A_2 is the area lying within the reinforcement zone resulting from any excess thickness available in the branch pipe wall:

$$A_2 = 2L(T_b - t_b)$$

(3) Area A_3 is the area lying within the reinforcement zone resulting from excess thickness available in the extruded outlet lip:

$$A_3 = 2r_o(T_o - T_b)$$

(g) *Reinforcement of Multiple Openings*. When any two or more adjacent openings are so closely spaced that the reinforcement zones overlap, the two or more openings shall be reinforced in accordance with ND-3643.4, with a combined reinforcement that has a strength equal to the combined strength of the reinforcement that would be required for separate openings. No portion of the cross section shall be considered as applying to more than one opening or be evaluated more than once in a combined area.

(h) *Marking*. In addition to the above, the Certificate Holder shall be responsible for establishing and marking on the section containing extruded outlets, the Design Pressure and Temperature, and the Certificate Holder's name or trademark.

ND-3643.5 Branch Connections Subject to External Pressure

(a) The reinforcement area in sq in. required for branch connections subject to external pressure shall be $0.54(t_{mh})(d_1)(2 - \sin \alpha)$. See ND-3643.3(c)(1).

(b) Procedures established for connections subject to internal pressure shall apply for connections subject to external pressure.

ND-3643.6 Reinforcement of Other Designs.

The adequacy of designs to which the reinforcement requirements of ND-3643 cannot be applied shall be proven by burst or proof tests (ND-3649) on scale models or on full-size structures, or by calculations previously substantiated by successful service of similar design.

ND-3644 Miters

Mitered joints may be used in piping systems under the conditions stipulated in (a) through (e) below.

(a) The thickness of a segment of a miter shall be determined in accordance with ND-3641.1. The required thickness thus determined does not allow for the discontinuity stresses which exist at the junction between segments. The discontinuity stresses are reduced for a given miter as the number of segments is increased. These discontinuity stresses may be neglected for miters in nonflammable, nontoxic, noncyclic services with incompressible fluids at pressures of 100 psi (690 kPa) and under, and for gaseous vents to atmosphere. Miters to be used in other services or at higher pressures shall meet the requirements of ND-3649.

(b) The number of full pressure or thermal cycles shall not exceed 7000 during the expected lifetime of the piping system.

(c) The angle θ in Fig. ND-3673.2(b)-1 shall not be more than $22\frac{1}{2}$ deg.

(d) The center line distance between adjacent miters shall be in accordance with Fig. ND-3673.2(b)-1.

(e) Full penetration welds shall be used in joining miter segments.

ND-3645 Attachments

(a) External and internal attachments to piping shall be designed so as not to cause flattening of the pipe, excessive localized bending stresses, or harmful thermal gradients in the pipe wall. It is important that such attachments be designed to minimize stress concentrations in applications where the number of stress cycles, due either to pressure or thermal effect, is relatively large for the expected life of the equipment.

(b) Attachments shall meet the requirements of ND-3135.

ND-3646 Closures

(a) Closures in piping systems shall be made by use of closure fittings, such as blind flanges or threaded or welded plugs or caps, either manufactured in accordance with standards listed in Table ND-3132-1 and used within the specified pressure-temperature ratings, or made in accordance with (b) below.

(b) Closures not manufactured in accordance with the standards listed in Table ND-3132-1 may be made in accordance with the rules contained in ND-3300 using the equation:

$$t_m = t + A$$

where

t_m	= minimum required thickness, in.
t	= pressure design thickness, calculated for the given closure shape and direction of loading using appropriate equations and procedures in ND-3000, in.
A	= sum of mechanical allowances (ND-3613), in.

(c) Connections to closures may be made by welding, extruding, or threading. Connections to the closure shall be in accordance with the limitations provided in ND-3643 for branch connections. If the size of the opening is greater than one-half the inside diameter of the closure, the opening shall be designed as a reducer in accordance with ND-3648.

(d) Other openings in closures shall be reinforced in accordance with the requirements of reinforcement for a branch connection. The total cross-sectional area required for reinforcement in any plane passing through the center of the opening and normal to the surface of the closure shall not be less than the quantity of $d_5^2 t$, where

d_5	= diameter of the finished opening, in.
t	= pressure design thickness for the closure, in.

ND-3647 Pressure Design of Flanged Joints and Blanks

ND-3647.1

ND-3647.1 Flanged Joints

(a) Flanged joints manufactured in accordance with the standards listed in Table ND-3132-1, as limited by ND-3612.1, shall be considered as meeting the requirements of ND-3640.

(b) Flanged joints not included in Table ND-3132-1 shall be designed in accordance with XI-3000.

ND-3647.2 Permanent Blanks.

The minimum required thickness of permanent blanks (Fig. ND-3647.2-1) shall be calculated from the following equations:

$$t_m = t + A$$

where

t_m	= the minimum required thickness, in.
t	= the pressure design thickness calculated from the equation below, in.
A	= the sum of the mechanical allowances, in. (ND-3613)

$$t = d_6 \left(\frac{3P}{16S} \right)^{1/2}$$

FIG. ND-3647.2-1 TYPES OF PERMANENT BLANKS

FIG. ND-3647.2-1 TYPES OF PERMANENT BLANKS

where

d_g

= the inside diameter of the gasket for raised or flat face flanges or the pitch diameter of the gasket for retained gasketed flanges, in.

P

= Design Pressure, psi

S

= the allowable stress in accordance with Tables 1A, 1B, and 3, Section II, Part D, Subpart 1, psi.

ND-3647.3 Temporary Blanks.

Blanks to be used for test purposes only shall have a minimum thickness not less than the pressure design thickness t calculated as in ND-3647.2, except that P shall not be less than the test pressure and the allowable stress S may be taken as 95% of the specified minimum yield strength of the blank material (Section II, Part D, Subpart 1, Tables 1A and 1B).

ND-3647.4 Flanges.

Flanges shall be integral or be attached to pipe by welding, brazing, threading, or other means within the applicable standards specified in Table ND-3132-1.

ND-3647.5 Gaskets

(a) Gaskets shall be made of materials which are not injuriously affected by the fluid or by temperatures within the Design Temperature range.

(b) Only metallic or asbestos metallic gaskets may be used on flat or raised face flanges if the expected normal service pressure exceeds 720 psi (4960 kPa) or the temperature exceeds 750°F (399°C). However, compressed sheet asbestos confined gaskets are not limited as to pressures, provided the gasket material is suitable for the temperatures.

(c) The use of metal or metal asbestos gaskets is not limited as to pressure, provided the gasket materials are suitable for the fluid Design Temperature.

ND-3647.6 Bolting

(a) Bolts, stud bolts, nuts, and washers shall comply with applicable standards and specifications listed in Table ND-3132-1. Unless otherwise specified, bolting

Page 152

shall be in accordance with the latest edition of ANSI B16.5. Bolts and stud bolts shall extend completely through the nuts.

(b) Studs shall be threaded full length or shall be machined down to the root diameter of the thread in the unthreaded portion, provided that the threaded portions are at least $1\frac{1}{2}$ diameters in length. Studs greater than 8 diameters in length may have an unthreaded portion which has the nominal diameter of the thread, provided the following requirements are met:

(1) the threaded portions shall be at least $1\frac{1}{2}$ diameters in length;

(2) the stud shall be machined down to the root diameter of the thread for a minimum distance of 0.5 diameters adjacent to the threaded portion; and

(3) a suitable transition shall be provided between the root diameter and unthreaded portions.

(c) Carbon steel bolts shall be ANSI Standard square or heavy hexagon head bolts and shall have ANSI Standard heavy semifinished hexagon nuts.

(d) Alloy steel stud bolts shall have ANSI Standard heavy hexagon nuts. Headed alloy bolts are not recommended.

(e) It is recommended that all alloy bolts or stud bolts and accompanying nuts be threaded in accordance with ANSI B1.1 Class 2A external threads and Class 2B internal threads.

ND-3648 Reducers

Reducer fittings manufactured in accordance with the standards listed in Table ND-3132-1 shall be considered suitable for use. Where butt welding reducers are made to a nominal pipe thickness, the reducers shall be considered suitable for use with pipe of the same nominal thickness.

ND-3649 Pressure Design of Other Pressure Retaining Piping Products

Other pressure retaining piping products manufactured in accordance with the standards listed in Table ND-3132-1 shall be considered suitable for use in piping systems at the specified pressure-temperature ratings. Pressure retaining piping products not covered by the standards listed in Table ND-3132-1 and for which design equations or procedures are not given in this Subsection may be used where the design of similarly shaped, proportioned, and sized components has been proven satisfactory by successful performance under comparable service conditions. Where such satisfactory service experience exists, interpolation may be made to other sized piping products with a geometrically similar shape. In the absence of such service experience, the pressure design shall be based on an analysis consistent with the general design philosophy of this Subsection and substantiated by at least one of the following:

(a) proof tests as described in ANSI B16.9;

(b) experimental stress analysis (Appendix II).

ND-3649.1 Expansion Joints - General Requirements.

Expansion joints of the bellows, sliding, ball, or swivel type may be used to provide flexibility for piping systems. The design of the piping systems and the design, material, fabrication, examination, and testing of the expansion joints shall conform to this Subsection and shall comply with the requirements of (a) through (e) below.

(a) Piping system layout, anchorage, guiding, and support shall be such as to avoid the imposition of motions or forces on the expansion joints other than those for the absorption of which they are both suitable and intended. Bellows expansion joints are normally not designed for absorbing torsion. Sliding expansion joints are normally not designed for absorbing bending. In sliding and bellows expansion joints used for absorbing axial motion, the hydrostatic end force caused by fluid pressure and the forces caused by either friction resistance or spring force, or both, should be resisted by rigid end anchors, cross connections of the section ends, or other means. Where reaction to hydrostatic end forces acts on pipe, guides shall be provided to prevent buckling in any direction. For bellows expansion joints, the pipe guiding and anchorage shall conform to EJMA Standards.²¹

(b) The expansion joints shall be installed in such locations as to be accessible for scheduled inspection and maintenance and for removal and replacement either directly or by other suitable means.

(c) Expansion joints employing mechanical seals shall be sufficiently leak-tight to satisfy safety requirements. The system designer shall specify the leak-tightness criteria for this purpose.

(d) Material shall conform to the requirements of ND-2000, except that no sheet material in the quenched, aged, or air-hardened condition shall be used for the flexible elements of a bellows joint. If heat treatment is required, it shall be performed either after welding the element into a complete cylinder or after all forming of the bellows is completed, the only welding permissible after such treatment being that required to connect the element to pipe or end flanges.

²¹ Expansion Joint Manufacturers Association, 331 Madison Avenue, New York, NY 10017.

(e) All welded joints shall comply with the requirements of ND-4800.

ND-3649.2 Bellows Expansion Joints.

Expansion joints of the bellows type may be used to provide flexibility for piping systems. The design, material, fabrication, examination, and testing of the expansion joints shall conform to this Subsection and the requirements of (a) through (f) below.

(a) The piping system layout, anchorage, guiding, and support shall be such as to avoid the imposition of motions or forces on the bellows other than those for which they have been designed.

(b) In all systems containing bellows, the hydrostatic end force caused by pressure and the bellows spring force shall be accommodated by or resisted by rigid anchors, cross connections of the expansion joint ends, or other means. Where bellows are used in straight pipe sections to absorb axial motion and where the hydrostatic end force of the bellows acts on the pipe as a column, guides must be provided to prevent buckling of the pipe in any direction. The pipe guiding and anchorage shall conform to the requirements of the Design Specification for the attached piping.

(c) The expansion joints shall be installed in such locations as to be accessible for scheduled inspection, where applicable.

(d) The joints shall be provided with bars or other suitable members for maintaining the proper face-to-face dimension during shipment and installation. Bellows shall not be extended or compressed to make up deficiencies in length or offset to accommodate connected piping which is not properly aligned, unless such misalignments have been specified by the system designer.

(e) The expansion joints shall be marked to show the direction of flow, if applicable, and shall be installed in accordance with this marking.

(f) Unless otherwise stated in the Design Specification, internal sleeves shall be provided when flow velocities exceed the following values:

Air, Steam, and Other Gases

Up to 6 in. (152 mm) diameter - 4 ft/sec/in. of diameter;

6 in. (152 mm) diameter and over - 25 ft/sec.

Water and Other Liquids

Up to 6 in. (152 mm) diameter - 2 ft/sec/in. of diameter;

6 in. (152 mm) diameter and over - 10 ft/sec.

ND-3649.3 Bellows Expansion Joint Material.

Pressure retaining material in the expansion joint shall conform to the requirements of ND-2000.

ND-3649.4 Bellows Expansion Joint Design.

Bellows may be of the unreinforced or reinforced convoluted type or of the toroidal type. The design shall conform to the requirements of ND-3000 and to those of (a) through (j) below.

(a) The circumferential membrane stresses in both the bellows and reinforcing member, due to pressure, shall not exceed the allowable stresses given in Section II, Part D, Subpart 1, Tables 1A and 1B.

(b) The sum of the bellows meridional membrane and bending stresses due to internal pressure shall not exceed a value which results in a permanent decrease in the spaces between adjacent convolutions of 7% after a pressure test of $1\frac{1}{2}$ times the Design Pressure, adjusted for temperature.

(c) The ratio of the internal pressure at which the bellows will become unstable (squirm) to the equivalent cold service pressure shall exceed 2.25. By definition, squirm shall be considered to have occurred if under internal pressure an initially symmetrical bellows deforms, resulting in a lack of parallelism or uneven spacing of adjacent convolutions at any point on the circumference. Unless otherwise specified, this deformation shall be construed as unacceptable squirm when the ratio of the maximum convolution pitch under internal pressure to the convolution pitch before application of pressure exceeds 1.15 for unreinforced and 1.20 for reinforced bellows. In the case of universal expansion joints, which consist of two bellows joined by a cylindrical section, compliance with these criteria shall be satisfied by the entire assembly. No external restraints on the bellows shall be employed during squirm testing other than those which will exist after installation.

(1) For single joints used in axial or lateral motion, the squirm test may be performed with the bellows fixed in the straight position at the maximum length expected in service; for rotation and universal joints, the bellows shall be held at the maximum design rotation angle or offset movement. In the case of single joints subjected to rotation movement or universal joints subjected to lateral offset movement, an instability condition as previously defined may or may not appear. Instead, movement of the convolutions may occur due to the superposition of the lateral internal pressure component on the applied rotation. In such cases, that portion of the bellows deformation due to the design rotation angle or offset movement shall not be included in the deformation used to define squirm.

Page 154

(2) In the case of squirm tests, the equivalent cold service pressure is defined as the Design Pressure multiplied by the ratio E_c/E_h , where E_c and E_h are defined as the modulus of elasticity of the bellows material at room temperature and normal service temperature, respectively.

(d) The combination of meridional membrane and bending stresses S in the bellows due to internal pressure and deflection, multiplied by a stress factor K_s ,²² shall not exceed the value defined by the following equation:

$$K_s S \leq S_f$$

where

$$K_s = (K_{sc})(K_{ss}), \text{ but not less than } 1.25$$

$$K_{sc} = \text{factor for differences in design fatigue curves at}$$

	temperatures greater than 100°F (38°C)
	$= 2S_c / (S_c + S_h)$
K_{ss}	= factor for the statistical variation in test results
	= 1.470 - 0.044 times the number of replicate tests
S	= total combined meridional membrane and bending stress due to pressure and deflection, psi. The calculation of the individual stress components and their combination must be determined by the same method as used for determining S_f . In the case of single joints subjected to rotation movement and universal joints subjected to lateral offset movement, the increase in deflection stress caused by the lateral internal pressure component shall be included in determining the combined stress.
S_f	= total combined stress to failure at design cyclic life (number of cycles to failure) obtained from plots of stress versus cyclic life based on data from fatigue tests of a series of bellows at a given temperature (usually room temperature) evaluated by a best-fit continuous curve or series of curves, psi. The S_f plot shall be parallel to the best-fit curve and shall lie below all of the data points.
S_c	= basic material allowable stress value at room temperature from Section II, Part D, Subpart 1, Tables 1A and 1B, psi
S_h	= basic material allowable stress value at normal service temperature from Section II, Part D, Subpart 1, Tables 1A and 1B, psi

(e) Compliance with (a) through (d) above shall be demonstrated by any one of the procedures of (1), (2), or (3) below.

22 See Appendix II, II-1520(g).

(1) Calculation of the individual stresses, their combination, and their relation to fatigue life may be performed by any analytical method based on elastic shell theory. The resulting equations shall be substantiated by correlation with actual tests of a consistent series of bellows of the same basic design (unreinforced, reinforced, and toroidal bellows are considered as separate designs) by each manufacturer in order to demonstrate predictability of rupture pressure, meridional yielding, squirm, and cyclic life. A minimum of five burst tests on bellows of varying sizes, with not less than three convolutions, shall be conducted to verify that the analytical method will adequately satisfy (a) and (b) above. No specimen shall rupture at less than four times its equivalent cold pressure rating. A minimum of ten squirm tests on bellows of varying diameters and number of convolutions shall be conducted to verify that the analytical method will adequately satisfy (c) above. Since column instability is most likely to occur in bellows less than 20 in. (508 mm) diameter, where the convoluted bellows length is greater than its diameter, the test specimens shall reflect these considerations. In the case of universal expansion joints, two additional tests shall be conducted to verify that the analytical method will adequately satisfy (c) above. The cyclic life versus the combined stress plot used in evaluating ND-3649.4(d) shall be obtained from the results of at least 25 fatigue tests on bellows of varying diameters, thicknesses, and convolution profiles. These curves may be used for diameter and convolution profiles other than those tested, provided that a variation in these dimensions has been included in the correlation with test data. Each group of five such tests on varying bellows may be considered the equivalent of one replicate test in determining K_s .

(2) Individual expansion joint designs may be shown to comply by the testing of duplicate bellows. At least two test specimens are required, one to demonstrate pressure capacity in accordance with (a), (b), and (c) above and the second to demonstrate fatigue life in accordance with (d) above. In the case of rupture and fatigue tests, the specimens need not possess a duplicate number of convolutions provided the number of convolutions is not less than three and the

diameter, thickness, depth, and pitch of the specimen are identical to the part to be furnished; squirm test specimens shall possess the total number of convolutions.

(a) Any or all of the above tests of (e)(1) or (e)(2) may be conducted at room temperature, provided that cold service pressure is defined as the Design Pressure multiplied by the ratio of S_c/S_h for rupture specimens and E_c/E_h for squirm specimens.

Page 155

(b) The fatigue life of the test specimen shall exceed $K_s^{4.3}$ times the number of design cycles specified for the most significant cyclic movements. This test shall include the effect of internal pressure. If lateral and rotation movements are specified, these may be converted to equivalent axial motion for cyclic testing; the convolution deflection produced by the lateral component of the internal pressure force during the squirm test for single rotation joints and universal joints shall be added to the mechanical deflections in determining fatigue life. Where accelerated fatigue testing is employed, the deflection and number of cycles required shall be in accordance with Appendix II. Cumulative fatigue requirements can be satisfied in accordance with ND-3649.4(g) without additional testing by assuming that the slope of the fatigue curve is 4.3 and that the curve passes through the test point.

(3) An individual design may be shown to comply by a design analysis in accordance with NC-3200. The stresses at every point in the bellows shall be determined by either elastic shell theory or by a plastic analysis, where applicable. Where an elastic analysis is employed, the stress intensity values of Tables 2A and 2B, Section II, Part D, Subpart 1, and fatigue curves of Figs. I-9.0 may be used to evaluate the design.

(a) The stability requirements of ND-3649.4(c) may be demonstrated by either:

(1) elastic stability calculations, provided that the ratio of the internal pressure at which the bellows is predicted to become unstable to the equivalent cold service pressure exceeds 10; or

(2) the pressure test of ND-6230, provided that the test is conducted at $2\frac{1}{4}$ times the equivalent cold design pressure, and single rotation and universal joints are held at their design rotation angle or offset movement during the test, and the requirements of ND-3649.4(b) are not exceeded by such a test.

(f) The Certificate Holder's Data Report shall state which of the above procedures was utilized to verify the design.

(g) If there are two or more types of stress cycles which produce significant stresses, their cumulative effect shall be evaluated as stipulated in Steps 1 through 5 below.

Step 1: Designate the specified number of times each stress cycle of types 1, 2, ..., n will be repeated during the life of the component as $n_1, n_2, \dots, n_n$ respectively.

NOTE: In determining $n_1, n_2, \dots, n_n$ consideration shall be given to the superposition of cycles of various origins which produce a total stress difference $S_1, S_2, \dots, S_n$ greater than the stress difference of the individual cycles. For example, if one type of stress cycle produces 1,000 cycles of stress difference variation from 0 to +60,000 psi and another type of stress cycle produces 10,000 cycles of a stress difference variation from 0 to -50,000 psi, the two types of cycles to be considered are defined by the following parameters:

Type 1 Cycle: n_1	= 1,000,
S_1	= (60,000 + 50,000)
	= 110,000 psi, and
Type 2 Cycle: n_2	= 9,000,
S_2	= (50,000 + 0) = 50,000 psi

Step 2: For each value $S_1, S_2, \dots, S_n$ use the applicable design fatigue curve and corresponding method of analysis to determine the maximum number of stress cycles which would be allowable if this type of cycle were the only one acting. Call these values $N_1, N_2, \dots, N_n$. The fatigue curve used may be either the S_f lot defined in ND-3649.4(d) or the curve consistent with ND-3649.4(e)(2) or (3). If the fatigue curve has been developed based on a total stress difference,

then the full value of $S_1, S_2, \dots, S_n$ of Step 1 must be used to determine N ; however, if the curve is based on an alternating stress, then the values of $S_1, S_2, \dots, S_n$ shall be reduced by a factor of 2, in which case $S_1, S_2, \dots, S_n$ become the alternating stresses.

Step 3: For each type of stress cycle, calculate the usage factors $U_1, U_2, \dots, U_n$ from $U_1 = n_1/N_1, U_2 = n_2/N_2, \dots, U_n = n_n/N_n$.

Step 4: Calculate the cumulative usage factor U from $U = U_1 + U_2 + \dots + U_n$.

Step 5: The cumulative usage factor U shall not exceed 1.0.

(h) The Certificate Holder shall submit a report which demonstrates compliance with ND-3649.

(i) Where necessary to carry the pressure, the cylindrical ends of the bellows may be reinforced by suitable collars. The design method used to assure that the stresses generated will not cause premature failure of the bellows material or weldment shall include the attachment weld between the bellows and end connections.

(j) The spring rates of the expansion joint assembly shall be provided by the Certificate Holder. The spring rates of a bellows can be defined by several methods due to the hysteresis loop which can occur during deflection; a restoring force may be required to return the bellows to the original neutral position after deflection. When applicable, the Design Specification shall state the maximum allowable force that can be imposed

Page 156

on the connecting parts or shall require the Certificate Holder to determine the maximum force necessary to deflect the bellows a given distance, such as the maximum movement to be absorbed.

ND-3650 ANALYSIS OF PIPING SYSTEMS

ND-3651 General Requirements²³

(a) The design of the complete piping system shall be analyzed between anchors for the effects of thermal expansion, weight, and other sustained and occasional loads. The system design shall meet the limits of ND-3650. The pressure portion of Eqs. (8) and (9) may be replaced with the expression:

$$S_{LP} = B_1 \frac{2Pd^2}{D_o^2 - d^2}$$

The pressure portion of Eq. (11) may be replaced by the expression:

$$S_{LP} = \frac{Pd^2}{D_o^2 - d^2}$$

where the terms are the same as in ND-3652, except:

P	= P or $P_{\max}$, psi
d	= nominal inside diameter of pipe, in.

(b) When evaluating stresses in the vicinity of expansion joints, consideration must be given to actual cross-sectional areas that exist at the expansion joint.

(c) For analysis of flanged joints, see ND-3658.

ND-3652 Consideration of Design Conditions

The effects of pressure, weight, and other sustained mechanical loads must meet the requirements of Eq. (8):

$$S_{SL} = B_1 \frac{PD_o}{2t_n} + B_2 \frac{M_A}{Z} \leq 1.5S_h \quad (8)$$

(8)

B_1, B_2	= primary stress indices for the specific product under investigation [Fig. ND-3673.2(b)-1]
P	= internal Design Pressure, psi
D_o	= outside diameter of pipe, in.
t_n	= nominal wall thickness, in.
M_A	= resultant moment loading on cross section due to weight and other sustained loads, in.-lb (ND-3653.3)
Z	= section modulus of pipe, in. ³

S_h

= basic material allowable stress at Design Temperature, psi

23 The pressure term in Eqs. (8), (9), and (11) may not apply for bellows and expansion joints.

ND-3653 Consideration of Levels A and B Service Limits

ND-3653.1 Occasional Loads.²⁴

The effects of pressure, weight, other sustained loads, and occasional loads, including nonreversing dynamic loads, for which Level B Service Limits are designated, must meet the requirements of Eq. (9):

$$S_{OL} = B_1 \frac{P_{\max} D_o}{2t_n} + B_2 \left(\frac{M_A + M_B}{Z} \right) \leq 1.8S_h \quad (9)$$

(9)

but not greater than $1.5S_y$. Terms are the same as in ND-3652, except:

 $P_{\max}$

= peak pressure, psi

 M_B

= resultant moment loading on cross section due to nonreversing dynamic loads.

 S_y

= material yield strength at temperature consistent with the loading under consideration, psi

 S_h

= material allowable stress at temperature consistent with the loading under consideration, psi

ND-3653.2 Thermal Expansion.

For Service Loadings for which Level A and B Service Limits are designated, the requirements of either Eq. (10), or Eq. (11), and Eq. (11a) must be met.

(a) The effects of thermal expansion must meet the requirements of Eq. (10):

$$S_E = \frac{iM_C}{Z} \leq S_A \quad (10)$$

(10)

Terms are the same as in ND-3652, except:

M_C

= range of resultant moments due to thermal expansion, in.-lb;
also include moment effects of anchor displacements due to
nonreversing dynamic loads if anchor displacement effects
were omitted from Eq. (9) (ND-3653.1)

S_A

= allowable stress range for expansion stresses (ND-3611.2),
psi

i

= stress intensification factor (ND-3673.2)

(b) The effects of any single nonrepeated anchor movements shall meet the requirements of Eq. (10a):

24 Design Pressure may be used if the Design Specification states that peak pressure and earthquake need not be taken as acting concurrently.

Page 157

$$\frac{iM_D}{Z} \leq 3.0S_c \quad (10a)$$

(10a)

Terms are the same as in ND-3653.2(a), except:

M_D

= resultant moment due to any single nonrepeated anchor
movement (e.g., predicted building settlement), in.-lb.

S_c

= basic material allowable stress at ambient temperature, psi

(c) The effects of pressure, weight, other sustained loads, and thermal expansion shall meet the requirements of Eq. (11):

$$S_{TE} = \frac{PD_o}{4t_n} + 0.75i\left(\frac{M_A}{Z}\right) + i\left(\frac{M_C}{Z}\right) \leq (S_h + S_A) \quad (11)$$

(11)

Terms are the same as in ND-3652 and ND-3653.2(a), except 0.75i shall not be less than 1.0.

(d) The effects of reversing dynamic loads must meet the requirements of Eq. (11a):

$$S_R = \frac{iM_R}{Z} \leq 3.0S_A \quad (11a)$$

(11a)

Terms same as in NC-3653.2(a), except:

M_R

= range of resultant moments due to inertia and anchor motion effects of reversing dynamic loads

[98]

ND-3653.3 Determination of Moments and Section Modulus

(a) For purposes of Eqs. (8), (9), (10), (10a), and (11), the resultant moment for straight through components, curved pipe, or welding elbows may be calculated as follows:

$$M_j = (M_{xj}^2 + M_{yj}^2 + M_{zj}^2)^{1/2}$$

where

j

= A, B, C, or D which are the subscripts of M_A, M_B, M_C, M_D defined in ND-3652, ND-3653.1, and ND-3653.2

(b) When evaluating Eqs. (8) and (9) for branch connections and tees, use the procedure for branch and run moments given in NB-3683.1(d). When evaluating Eqs. (10), (10a), and (11), use (c) and (d) below.

(c) For full outlet branch connections, calculate the resultant moment of each leg separately in accordance with (a) above. Moments are to be taken at the junction point of the legs (Fig. ND-3653.3-1).

**FIG. ND-3653.3-1 REDUCING OR FULL OUTLET
BRANCH CONNECTIONS, OR TEES**

FIG. ND-3653.3-1 REDUCING OR FULL OUTLET BRANCH CONNECTIONS, OR TEES

(d) For reduced outlets, calculate the resultant moment of each leg separately in accordance with (a) above. Moments are to be taken at the junction point of the legs (Fig. ND-3653.3-1), except that for $r'_m/r < 0.5$ the branch moments at the outside surface of the run pipe may be used for the branch leg. For the reduced outlet branch:

$$M_A M_B M_C M_D = (M_{x3}^2 + M_{y3}^2 + M_{z3}^2)^{1/2}$$

and

Z	$= \pi(r'_m)^2 t_s$, in. ³ , except as otherwise defined in Fig. ND-3673.2(b)-1
r	= run pipe mean cross-sectional radius, in.
r'_m	= branch mean cross-sectional radius, in.
t_s	= effective branch wall thickness, in.
	= lesser of T_r or iT_b
T_b	= nominal branch wall thickness, in.
T_r	= nominal wall thickness of run pipe, in.

For the main run outlets, use M_A , M_B , M_C , and M_D , as defined in ND-3653.3(a).

[98]

ND-3654 Consideration of Level C Service Limits

ND-3654.1 Permissible Pressure.

When Level C Service Limits [NCA-2142.4(b)(3) and NB-3113(b)] are

Page 158

specified, the permissible pressure shall not exceed the pressure P_a , calculated in accordance with Eq. (5) of ND-3641.1, by more than 50%.

ND-3654.2 Analysis of Piping Components.

For Service Loadings for which Level C Service Limits [NCA-2142.4(b)(3) and NB-3113(b)] are designated, the requirements of (a) or (b) below shall apply.

(a) For Service Loadings for which Level C Service Limits are designated, which do not include reversing dynamic loads or have reversing dynamic loads combined with nonreversing dynamic loads, the conditions of Eq. (9) of ND-3653.1 shall be met using Service Level C coincident pressure P and moments M_t which result in the maximum calculated stress. The allowable stress to be used for this condition is $2.25S_h$ but not greater than $1.8S_y$.

(b) For Service Loadings for which Level C Service Limits are designated, which include reversing dynamic loads that are not required to be combined with nonreversing dynamic loads, the requirements of ND-3655(b) shall be satisfied, using the allowable stress in ND-3656(b)(2), 70% of the allowable stress in ND-3655(b)(3), and 70% of the allowable loads in ND-3656(b)(4).

ND-3654.3 Deformation Limits.

Any deformation or deflection limits prescribed by the Design Specifications shall be considered with respect to Level C Service Limits.

ND-3655 Consideration of Level D Service Limits

If the Design Specifications specify any Service Loading for which Level D Limits are designated [NCA-2142.2(b)(4)], the requirements of (a), (b), or (c) below shall apply.

(a) For Service Loadings for which Level D Service Limits are designated, which do not include reversing dynamic loads or have reversing dynamic loads combined with nonreversing dynamic loads, the requirements of (1) and (2) below shall apply.

(1) The permissible pressure shall not exceed 2.0 times the pressure P_a calculated in accordance with Eq. (3) of ND-3641.1.

(2)

not greater than $2.0S_y$.

h

(b) For piping fabricated from material designated P-No. 1 through P-No. 9 in Table 2A, Section II, Part D and limited to $D_o/t_n \leq 50$, if Level D Service Limits are designated, which include reversing dynamic loads that are not required to be combined with nonreversing dynamic loads, the requirements of (1) through (5) below shall apply.

(1) The pressure occurring coincident with the earthquake or other reversing type loading shall not exceed the Design Pressure.

(2) The sustained stress due to weight loading shall not exceed the following:

$$B_2 \frac{D_o}{2I} M_W \leq 0.5S_m$$

where

M_W = resultant moment due to weight effects

(3) The stress due to weight and inertial loading due to reversing dynamic loads in combination with the Level D coincident pressure shall not exceed the following:

$$B_1 \frac{P_D D_o}{2t} + B_2 \frac{D_o}{2I} M_E \leq 4.5S_m$$

where

P_D = the pressure occurring coincident with the reversing dynamic load

M_E

= the amplitude of the resultant moment due to the inertial loading from the earthquake, other reversing type dynamic events and weight. Earthquake and other reversing dynamic loads shall be computed from a linear elastic response spectrum analysis as defined in Appendix N-1226, except the spectrum peak broadening value Δ_{fg} in N-1226.3 shall not be less than 15% and, in place of the damping values for both large and small diameter piping systems in Table N-1230-1 for Operating Basis Earthquake and Safe Shutdown Earthquake, a value of 5 shall be used. The ground motion design input for generating the floor response spectrum to be used in the linear elastic analysis shall meet the requirements of Appendix N-1211(a) and N-1211(b). Moments and forces may be computed using a methodology other than prescribed above if the alternate methodology is demonstrated to produce results which envelope the prescribed methodology results. In the combination of loads, all directional moment components in the same direction shall be combined before determining the resultant moment. If the method of analysis is such that only magnitude without algebraic signs are obtained, the most conservative combination shall be assumed.

Page 159

(4) The range of the resultant moment M_{AM} and the amplitude of the longitudinal force F_{AM} resulting from the anchor motions due to earthquake and other reversing type dynamic loading shall not exceed the following:

$$C_2 \frac{M_{AM} D_O}{2I} < S_1$$

$$\frac{F_{AM}}{A_M} < S_2$$

where

S_1	$= 6S_m$
S_2	$= 1.0S_m$
A_M	= cross-sectional area of metal in the piping component wall

(5) Piping displacements shall satisfy Design Specification limitations.

(c) As an alternative to ND-3655(a) and (b), the rules contained in Appendix F may be used in evaluating these service loadings independently of all other Design and Service Loadings.

ND-3658 Analysis of Flanged Joints

The pressure design of flanged joints is covered by ND-3647.1. Flanged joints subjected to combinations of moment and pressure shall meet the requirements of either ND-3658.1, ND-3658.2, or ND-3658.3. In addition, the pipe-to-flange welds shall meet the requirements of ND-3651 through ND-3655 using appropriate stress intensification factors from Fig. ND-3673.2(b)-1. The following nomenclature applies for ND-3658:

P	= Design or Service Condition Pressure as defined in NCA-2140, psi
P_{eq}	= equivalent pressure to account for the moments applied to the flange joint during the Condition, psi
M_{fs}	= bending or torsional moment (considered separately) applied to the joint due to weight, thermal expansion of the piping, sustained anchor movements, relief valve steady-state thrust, and other sustained mechanical loads applied to the flanged joint during the design or service condition, in.-lb. If cold springing is used, the moment may be reduced to the extent permitted by ND-3673.5.
M_{fd}	= bending or torsional moment (considered separately) as defined for M_{fs} but including dynamic loadings applied to the flanged joint during the design or service condition, in.-lb
G	= diameter at location of gasket load reaction as defined in XI-3130, in.
A_b	= total cross-sectional area of bolts at root of thread or section of least diameter under stress, sq in.
C	= bolt circle diameter, in.
S	= allowable bolt stress for the bolt material, psi
S_y	= yield strength, psi, of flange material at Design Temperature (Table Y-1, Section II, Part D, Subpart 2)
D_f	= outside diameter of raised face, in.
P_{fd}	= pressure concurrent with M_{fd} , psi

ND-3658.1 Any Flanged Joint.

Flanged joints may be analyzed and the stresses evaluated by using the methods given in Appendix XI as modified by ND-3658.1(a) or by ND-3658.1(b). Alternatively, they may be analyzed in accordance with Appendix XIII.

(a) If the flanged joint conforms to one of the standards listed in Table ND-3132-1, and if each P' , as calculated by (b) is less than the rated pressure at the Design or Service Temperature utilized, the requirements of ND-3658 are satisfied.

(b) The Design Pressure used for the calculation of H in Appendix XI shall be replaced by a flange design pressure

$$P' = P + P_{eq}$$

The equivalent pressure P_{eq} shall be determined by the greater of:

$$P_{eq} = 16M_{fs}/\pi G^3$$

or

$$P_{eq} = 8M_{fd}/\pi G^3$$

ND-3658.2 Standard Flanged Joints at Moderate Pressures and Temperatures.

Flanged joints conforming to ANSI B16.5, MSS SP-44, API 605, or AWWA C207 Class E (275 psi), and used where neither the Design nor Service Pressure exceeds 100 psi and neither the Design nor Service Temperature exceeds 200°F, meet the requirements of ND-3658, provided the following equations are satisfied:

$$M_{fs} \leq A_b CS/4$$

and

$$M_{fd} \leq A_b CS/2$$

Page 160

ND-3658.3 ANSI B16.5, Flanged Joints With High Strength Bolting.

Flanged joints using flanges, bolting, and gaskets as specified in ANSI B16.5 and using bolting material having an S value at 100°F not less than 20,000 psi may be analyzed in accordance with the following rules.

(a) *Design Limits and Levels A and B Service Limits*

(1) The pressure shall not exceed the rated pressure for Level A Service Limits or 1.1 times the rated pressure for Level B Service Limits.

(2) The limitations given by Eqs. (12) and (13) shall be met:

$$(12) M_{fs} \leq 3125(S_y/36,000) CA_b$$

$$(13) M_{fd} \leq 6250(S_y/36,000) CA_b$$

where the value of $S_y/36,000$ shall not be taken as greater than unity.

(b) *Level C Service Limits*

(1) The pressure shall not exceed 1.5 times the rated pressure.

(2) The limitation given by Eq. (17) shall be met:

$$(17) M_{fd} \leq [11,250A_b - (\pi/16)D_f^2 P_{fd}] C(S_y/36,000)$$

where the value of $S_y/36,000$ shall not be taken as greater than unity.

(c) *Level D Service Limits*

(1) The pressure shall not exceed 2.0 times the rated pressure.

(2) The limitation given by Eq. (17) shall be met, where P_{fd} and M_{fd} are pressures, psi, and moments, in.-lb, occurring concurrently.

(d) *Test Loadings.* Analysis for test loadings is not required.

ND-3660 DESIGN OF WELDS

ND-3661 Welded Joints

ND-3661.1 General Requirements.

Welded joints shall be in accordance with the requirements of ND-4200 except as limited herein.

ND-3661.2 Butt Welded Joints

(a) Girth welds shall be Type 1, 2, or 3 (ND-4245).

(b) Longitudinal welds shall be Type 1 (ND-4245).

ND-3661.3 Socket Welded Joints²⁵

Socket welds shall comply with the requirements of ND-4427.

ND-3661.4 Fillet Welds and Partial Penetration Welds for Branch Connections²⁶

(a) Fillet welds and partial penetration welds may be used within the limitations of ND-3643.1(c).

(b) For fillet welds, the size of the weld shall be specified on the design drawings.

(c) For partial penetration welds, the size of the weld, the depth of the weld groove, and the groove angle shall be specified on the design drawings.

ND-3670 SPECIAL PIPING REQUIREMENTS

ND-3671 Selections and Limitations of Nonwelded Piping Joints

The type of piping joint used shall be suitable for the Design Loadings and shall be selected with consideration of joint tightness, mechanical strength, and the nature of the fluid handled.

ND-3671.1 Flanged Joints.

Flanged joints shall conform to ND-3647 and ND-3658.

ND-3671.2 Expanded or Rolled Joints.

Expanded or rolled joints may be used when experience or test (ND-3649) has demonstrated that the joint is suitable for the Design Loadings and when adequate provisions are made to prevent separation of the joint.

ND-3671.3 Threaded Joints.

Threaded joints may be used within the limitations specified in (a), (b), and (c) below.

(a) All threads on piping products shall be taper pipe threads in accordance with the applicable standard listed in Table ND-3132-1. Threads other than taper pipe threads may be used for piping components where tightness of the joint depends on a seal weld or a seating surface other than the threads and when experience or test (ND-3649) has demonstrated that such threads are suitable.

(b) Threaded joints shall not be used when severe erosion, crevice corrosion, shock, or vibration is expected to occur. Size limits for steam and hot water service above 220°F shall be as follows:

²⁵ Socket welded joints should not be used where the existence of crevices could result in accelerated corrosion.

²⁶ Fillet and partial penetration welds should not be used where severe vibration is expected.

Nominal Size, in.	Pressure, psi
3	400
2	600
1	1,200
$\frac{3}{4}$ and less	1,500

(c) Pipe with a wall thickness less than that of standard weight of ANSI B36.10 steel pipe shall not be threaded, regardless of service. When steel pipe is threaded and used in steam service over 250 psi (1720 kPa) or water service above 100 psi (690 kPa) and 220°F (104°C), the pipe shall be seamless and at least Schedule 80.

ND-3671.4 Flared, Flareless, and Compression Joints.

Flared, flareless, and compression type tubing fittings may be used for tube sizes not exceeding 2 in. O.D. within the limitations of applicable standards and specifications in Table ND-3132-1 and as specified in (a) through (e) below.

(a) Fittings and their joints shall be compatible with the tubing with which they are to be used and shall conform to the range of wall thicknesses and method of assembly recommended by the manufacturer.

(b) Fittings shall be used at pressure-temperature ratings not exceeding the recommendations of the manufacturer. Service Conditions, such as vibration and thermal cycling, shall be considered in the application.

(c) All threads on piping products shall be taper pipe threads in accordance with applicable standards listed in Table ND-3132-1. Exceptions are that threads other than taper pipe threads may be used for piping components where tightness of the joint depends on a seating surface other than the threads and when experience or tests (ND-3649) have demonstrated that such threads are suitable.

(d) In the absence of standards or specifications, the designer shall determine that the type of fitting selected is adequate and safe for the Design Loadings in accordance with the following requirements.

(1) The pressure design shall meet the requirements of ND-3649.

(2) Prototypes of the fittings to be used shall successfully meet performance tests (ND-3649) to determine the safety of the joint under simulated Service Loadings. When vibration, fatigue, cyclic conditions, low temperature, thermal expansion, or hydraulic shock are expected, the applicable conditions shall be incorporated in the test.

(e) Flareless fittings shall be of a design in which the gripping member or sleeve shall grip or bite into the outer surface of the tube with sufficient strength to hold the tube against pressure but without appreciably distorting the inside tube diameter. The gripping member shall also form a pressure seal against the fitting body.

(1) When using bite-type fittings, a spot check shall be made for adequate depth of bite and condition of tubing by disassembling and reassembling selected joints.

(2) Grip-type fittings that are tightened in accordance with manufacturer's instructions need not be disassembled for checking.

ND-3671.5 Caulked Joints.

Caulked or leaded joints shall not be used.

ND-3671.6 Brazed and Soldered Joints

(a) *Brazed Joints.* Brazed joints shall be socket-type, and the minimum socket depth shall be sufficient for the intended service, but in no case less than that specified in Fig. ND-4511-1.

(b) *Soldered Joints.* Soldered joints shall be socket-type and shall be made in accordance with applicable standards listed in Table ND-3132-1.

(c) *Limitations of Brazed and Soldered Joints*

(1)

hazards are involved.

(2) Soldered socket-type joints shall be limited to systems containing nonflammable and nontoxic fluids.

(3) Soldered socket-type joints shall not be used in piping subject to mechanical or thermal shock, or vibration.

(4) Brazed or soldered joints depending solely upon a fillet, rather than primarily upon brazing or soldering material between the pipe and socket, are not acceptable.

(5) Soldered joints shall be pressure and temperature rated in accordance with the applicable standards in Table ND-3132-1, except that they shall not be used at pressures in excess of 175 psi (1207 kPa) or at temperatures in excess of 250°F (121°C).

ND-3671.7 Sleeve-Coupled and Other Patented Joints.

Coupling-type, mechanical gland-type, and other patented joints may be used where experience or tests have demonstrated to the satisfaction of the designer that the joint is safe for the Design Loadings and when adequate provision is made to prevent separation of the joint.

ND-3672 Expansion and Flexibility

ND-3672.1 General Requirements

(a) In addition to the design requirements for pressure, weight, and other loadings, piping systems subject

Page 162

to thermal expansion or contraction or to similar movements imposed by other sources shall be designed in accordance with the requirements for the evaluation and analysis of flexibility and stresses specified in this paragraph.

(b) Piping shall meet the expansion and flexibility requirements of this Subarticle except that, where Class 3 piping is connected to Class 1 piping, the requirements for expansion and flexibility for Class 1 piping shall apply to the Class 3 piping out to the first anchor on the Class 3 piping. However, the effect of expansion stresses in combination with stresses from other causes shall be evaluated in accordance with ND-3650. Other exceptions as stated in the following subparagraphs shall apply.

ND-3672.2 Properties.

Thermal expansion data and moduli of elasticity shall be determined from Tables TE and TM, Section II, Part D, Subpart 2, which cover more commonly used piping materials. For material not included in these Tables, reference shall be to authoritative source data such as publications of the National Institute of Standards and Technology.

ND-3672.3 Thermal Expansion Range.

The thermal expansion range shall be determined from Table TE, Section II, Part D, Subpart 2 as the difference between the unit expansion shown for the highest metal temperature and that for the lowest metal temperature resulting from service and shutdown conditions.

ND-3672.4 Moduli of Elasticity.

The cold and hot moduli of elasticity E_c and E_h shall be as shown in Table TM, Section II, Part D, Subpart 2 for the material based on the temperatures established in ND-3672.3.

ND-3672.5 Poisson's Ratio.

Poisson's ratio, when required for flexibility calculations, shall be taken as 0.3 at all temperatures for all materials.

ND-3672.6 Stresses.

Calculations for the stresses shall be based on the least cross-sectional area of the pipe or fitting, using nominal

dimensions at the location of local strain. Calculations for the expansion stress S_E shall be based on the modulus of elasticity at room temperature E_c .

(a) *Stress Range.* Stresses caused by thermal expansion, when of sufficient initial magnitude, relax in the hot condition as a result of local yielding or creep. A stress reduction takes place and usually appears as a stress of reversed sign when the component returns to the cold condition. This phenomenon is designated as self-springing of the line and is similar in effect to cold springing. The extent of self-springing depends on the material, the magnitude of the initial expansion and fabrication stress, the hot service temperature, and the elapsed time. While the expansion stress in the hot condition tends to diminish with time, the sum of the expansion strains for the hot and cold conditions during any one cycle remains substantially constant. This sum is referred to as the strain range; however, to permit convenient association with allowable stress, stress range is selected as the criterion for the thermal design of piping.

(b) *Local Overstrain.* All the commonly used methods of piping flexibility analysis assume elastic behavior of the entire piping system. This assumption is sufficiently accurate for systems in which plastic straining occurs at many points or over relatively wide regions but fails to reflect the actual strain distribution in unbalanced systems in which only a small portion of the piping undergoes plastic strain or in which, for piping operating in the creep range, the strain distribution is very uneven. In these cases, the weaker or higher stressed portions will be subjected to strain concentrations due to elastic follow-up of the stiffer or lower stressed portions. Unbalance can be produced:

(1) by use of small pipe runs in series with larger or stiffer pipe, with the small lines relatively highly stressed;

(2) by local reduction in size or cross section, or local use of a weaker material;

(3) in a system of uniform size, by use of a line configuration for which the neutral axis or thrust line is situated close to the major portion of the line itself, with only a very small offset portion of the line absorbing most of the expansion strain.

(c) Conditions of this type shall be avoided, particularly where materials of relatively low ductility are used; if unavoidable, they shall be mitigated by the judicious application of cold spring.

(d) It is recommended that the design of piping systems of austenitic steel materials be approached with greater overall care as to general elimination of local stress raisers, examination, material selection, fabrication quality, and erection.

ND-3672.7 Flexibility.

Piping systems shall be designed to have sufficient flexibility to prevent pipe movements from causing failure from overstress of the pipe material or anchors, leakage at joints, or detrimental distortion of connected equipment resulting from excessive thrusts and moments. Flexibility shall be provided by changes of direction in the piping through the use of bends, loops, or offsets; or provisions shall be made to absorb thermal movements by utilizing expansion, swivel, or ball joints or corrugated pipe.

Page 163

ND-3672.8 Expansion, Swivel, or Ball Joints.

Expansion, swivel, or ball joints, if used, shall conform to the requirements and limitations of ND-3649.

ND-3673 Analysis

ND-3673.1 Method of Analysis.

All systems shall be analyzed for adequate flexibility by a structural analysis unless one of the following conditions is met:

(a) The system can be judged technically adequate by an engineering comparison with previously analyzed systems.

(b) The operating temperature of the piping system is at or below 150°F and the piping is laid out with inherent flexibility, as provided in ND-3672.7.

(c) The operating temperature of the piping system is at or below 250°F and the piping is analyzed for flexibility using simplified methods of calculation such as handbooks or charts.

simplified methods of calculation such as handbooks or charts.

[98]

ND-3673.2 Basic Assumptions and Requirements

(a) When calculating the flexibility of a piping system between anchor points, the system between anchor points shall be treated as a whole. The significance of all parts of the line and of all restraints, such as supports or guides, including intermediate restraints introduced for the purpose of reducing moments and forces on equipment or small branch lines, shall be considered.

(b) Comprehensive calculations shall take into account the flexibility factors found to exist in piping products or joints other than straight pipe. Credit may be taken where extra flexibility exists in such products or joints. Flexibility factors and stress intensification factors for commonly used piping products and joints are shown in Fig. ND-3673.2(b)-1. The stress intensification factors and flexibility factors in Fig. ND-3673.2(b)-1 shall be used unless specific experimental or analytical data exist that would warrant lower stress intensification factors or higher flexibility factors.

(c) Flexibility factors are identified herein by k with appropriate subscripts. The general definition of a flexibility factor is:

$$k = \theta_{ab} / \theta_{nom}$$

where

θ_{ab} = rotation of end a , with respect to end b , due to a moment load M and in the direction of the moment M

θ_{nom} = nominal rotation of equivalent straight pipe due to moment load M

The flexibility factor k is defined in detail for specific components in Fig. ND-3673.2(b)-1.

(d) Stress intensification factors are identified herein by i . The definition of a stress intensification factor is based on fatigue bend testing of mild carbon steel fittings and is:

$$iS = 245,000 N^{0.2}$$

where

S = amplitude of the applied bending stress at the point of failure (psi)

N = number of cycles to failure

i = stress intensification factor

= ratio of the bending moment producing fatigue in a given number of cycles in a straight pipe with a girth butt weld to that producing failure in the same number of cycles in the fitting or joint under consideration.

(e) For piping products or joints not listed in Fig. ND-3673.2(b)-1, flexibility or stress intensification factors shall be established by experimental or analytical means.

(f) Experimental determination of flexibility factors shall be in accordance with Appendix II, II-1900. Experimental determination of stress intensification factors shall be in accordance with Appendix II, II-2000.

(g) Analytical determination of flexibility factors shall be consistent with the definition above.

(h) Analytical determination of stress intensification factors may be based on the empirical relationship

$$i = C_2 K_2 / 2, \text{ but not less than } 1.0$$

where C_2 and K_2 are stress indices for Class 1 piping products or joints from NB-3681(a)-1, or are determined as explained below.

Analytical determination of stress intensification factors shall be correlated with experimental fatigue results. Experimental correlation may be with new test data or with test data from similar products or joints reported in literature. Finite element analyses or other stress analysis methods may be used to determine C_2 ; however, test or established stress concentration factor data should then be used to determine K_2 .

(i) For certain piping products or joints the stress intensification factor may vary depending on the direction of the applied moment, such as in an elbow or branch connection. For these cases, the stress intensification factor used in Eqs. (10), (10a), and (11) of ND-3653.2

Page 164

shall be the maximum stress intensification factor for all loading directions as determined in accordance with (f) or (h) above.

(j) Stress intensification factors determined in accordance with (f) above shall be documented in accordance with Appendix II, II-2050. The test report may be included and certified with the Design Report (NCA-3551.1 and NCA-3555) for the individual piping system or a separate report furnished (II-2050).

(k) Stress intensification factors determined in accordance with (h) above shall be documented in a report with sufficient detail to permit independent review. The review shall be performed by an engineer competent in the applicable field of design in accordance with Appendix XXIII. The report shall be included and certified as part of the design report for the piping system (NCA-3551.1 and NCA-3555).

(l) The total expansion range as determined from ND-3672.3 shall be used in all calculations, whether or not the piping is cold sprung. Expansion of the line, linear and angular movements of the equipment, supports, restraints, and anchors shall be considered in the determination of the total expansion range.

(m) Where simplifying assumptions are used in calculations or model tests, the likelihood of underestimates of forces, moments, and stresses, including the effects of stress intensification, shall be evaluated.

(n) Dimensional properties of pipe and fittings used in flexibility calculations shall be based on nominal dimensions.

(o) When determining stress intensification factors by experimental methods, ND-3653.3(d) shall not apply. The nominal stress at the point under consideration (crack site, point of maximum stress, etc.) shall be used.

[98]

ND-3673.3 Cold Springing.

The beneficial effect of judicious cold springing in assisting a system to attain its most favorable position is recognized. Inasmuch as the life of a system under cyclic conditions depends on the stress range rather than the stress level at any one time, no credit for cold spring is allowed with regard to stresses. In calculating end thrusts and moments acting on equipment, the actual reactions at any one time, rather than their range, shall be used. Credit for cold springing is allowed in the calculations of thrusts and moments, provided the method of obtaining the designed cold spring is specified and used.

ND-3673.4 Movements.

Movement caused by thermal expansion and loadings shall be determined for consideration of obstructions and design of proper supports.

[98]

ND-3673.5 Computing Hot and Cold Reactions

(a) In a piping system with no cold spring or an equal percentage of cold springing in all directions, the reactions of R_h and R_c in the hot and cold conditions, respectively, shall be obtained from the reaction R derived from the flexibility calculations based on the modulus of elasticity at room temperature E_c using Eqs. (14) and (15):

$$R_h = \left(1 - \frac{2}{3}C\right) \left(\frac{E_h}{E_c}\right) R \quad (14)$$

$$R_c = CR$$

$$= \left[1 - \frac{(S_h)}{(S_E)} \cdot \frac{(E_c)}{(E_h)}\right] R \quad (15)$$

(14 - 15) whichever is greater, and with the further condition that

$$\frac{(S_h)}{(S_E)} \cdot \frac{(E_c)}{(E_h)} < 1$$

where

C

= cold spring factor varying from zero for no cold spring to 1.00 for 100% cold spring

S_E

= computed expansion stress, psi [ND-3653.2(a)]

E_c

= modulus of elasticity in the cold condition, psi

E_h

= modulus of elasticity in the hot condition, psi

R

= maximum reaction for full expansion range based on E_c which assumes the most severe condition (100% cold spring, whether such is used or not), lb

$R_c R_h$

= maximum reactions estimated to occur in the cold and hot conditions, respectively, lb

(b) If a piping system is designed with different percentages of cold spring in various directions, Eqs. (14) and (15) are not applicable. In this case, the piping system shall be analyzed by a comprehensive method. The calculated hot reactions shall be based on theoretical cold springs in all directions not greater than two-thirds of the cold springs as specified or measured.

[98]

ND-3673.6 Reaction Limits.

The reactions computed shall not exceed limits which the attached equipment can safely sustain.

FIG. ND-3673.2(b)-1 STRESS INDICES, FLEXIBILITY, AND STRESS INTENSIFICATION FACTORS ($D_o/t_n \leq 100$) [Notes (11), (12), (13)] (CONT'D)

NOTES:

- (1) Where flanges are attached to one or both ends, the values of k and i shall be corrected by the factor c given below.
 - (a) One end flanged, $c = h^{1/6}$
 - (b) Both ends flanged, $c = h^{1/3}$
- (2) B_1 and B_2 primary stress indices for these products are in course of preparation. In the interim, use $B_1 = 0.5$ and $B_2 = 0.75 i$.
- (3) Also includes single miter joints.
- (4) When $t_o > 1.5 t_n$, $h = 4.05 t_n/r$
- (5) The equation applies only if the following conditions are met.
 - (a) The reinforcement area requirements of ND-3643 are met.
 - (b) The axis of the branch pipe is normal to the surface of run pipe wall.
 - (c) For branch connections in a pipe, the arc distance measured between the centers of adjacent branches along the surface of the run pipe is not less than three times the sum of their inside radii in the longitudinal direction or not less than two times the sum of their inside radii along the circumference of the run pipe.
 - (d) The inside corner radius r_1 [Fig. ND-3673.2(b)-2] for nominal branch pipe size greater than 4 in. shall be between 10% and 50% T_r . The radius r_1 is not required for nominal branch pipe size smaller than 4 in.
 - (e) The outer radius r_2 is not less than the larger of $T_o/2$, $(T_b + Y)/2$ [Fig. ND-3673-2 sketch (c)] or $T_r/2$.
 - (f) The outer radius r_3 is not less than the larger of
 - (1) $0.002 \theta D_o$
 - (2) $2 (\sin \theta)^3$ times the offset for the configurations shown in Fig. ND-3673.2(b)-2 sketches (a) and (b).
 - (g) $R_m/T_r \leq 50$ and $r_m/R_m \leq 0.5$.
 - (h) The outer radius r_2 is not required provided an additional multiplier of 2.0 is included in the equations for branch end and run end stress intensification factors. In this case, the calculated value of i for the branch or run shall not be less than 2.1.
- (6) For checking branch leg stress: $Z = \pi (r_m)^2 T_b$.
- (7) In Fig. ND-4427-1(c-1) and (c-2), C_x shall be taken as X_{min} and $C_x \geq 1.25 t_n$. In Fig. ND-4427-1(c-3), $C_x \geq 0.75 t_n$. For unequal leg lengths use the smaller leg length for C_x .
- (8) The equation applies only if the following conditions are met.
 - (a) Cone angle α does not exceed 60 deg.
 - (b) The larger of D_o/t_1 and D_o/t_2 does not exceed 100.
 - (c) The wall thickness is not less than t_1 throughout the body of the reducer, except in and immediately adjacent to the cylindrical portion on the small end, where the thickness shall not be less than t_2 .
 - (d) For eccentric reducers, α is the maximum cone angle.
- (9) Factors shown apply to bending; flexibility factor for torsion equals 0.9.
- (10) The designer is cautioned that cast butt welding elbows may have considerably heavier walls than that of the pipe with which they are used. Large errors may be introduced unless the effect of these greater thicknesses is considered.
- (11) The following nomenclature applies:

r = mean radius of pipe, in. (matching pipe for tees and elbows)
 t_1 = nominal wall thickness of pipe, in. (matching pipe for tees and elbows, see Note (10))
 R = nominal bend radius of elbow or pipe bend, in.
 θ = one-half angle between adjacent miter axes, deg
 s = miter spacing at center line, in.
 t_o = reinforced thickness, in.
 D_o = nominal outside diameter, in.
- (12) For branch connections nomenclature, refer to Figs. ND-3643.2(b)-2 and ND-3673.2(b)-2.
- (13) The flexibility factors k and stress intensification factors i , and stress indices B_2 apply to bending in any plane for fittings and shall in no case be taken less than 1.0. They apply over the effective arc length (shown by heavy center lines in the sketches) for curved and miter elbows, and to the intersection point for tees.
- (13) Primary stress indices are applicable to $D_o/t_n \leq 50$ and stress intensification factors are applicable to $D_o/t_n \leq 100$.

FIG. ND-3673.2(b)-1 STRESS INDICES, FLEXIBILITY, AND STRESS INTENSIFICATION FACTORS ($D_o/t_n \leq 100$) [Notes (11), (12), (13)] (CONT'D)

d_o = outside diameter of branch pipe, in.
 r'_m = mean radius of branch pipe, in.
 T'_b = nominal thickness of branch pipes, in.
 R_m = mean radius of run pipe, in.
 T_r = nominal thickness of run pipe, in.

GENERAL NOTES:

- (a) T_b , θ , r_1 , r_2 , r_3 , r_p , and y are defined in this figure.
 (b) If L_1 equals or exceeds $0.5 \sqrt{r_1 T_b}$, where r_1 is the inside radius of the branch, then r'_m can be taken as the radius to the center of T_b .

FIG. ND-3673.2(b)-2 BRANCH DIMENSIONS

[98]

FIG. ND-3673.2(b)-2 BRANCH DIMENSIONS

ND-3674 Design of Pipe Supporting Elements

Supporting elements, including hangers, anchors, and sliding supports, shall be designed in accordance with the requirements of Subsection NF.

ND-3677 Pressure Relief Piping

ND-3677.1 General Requirements.

Pressure relief piping within the scope of this Subarticle shall be supported to sustain reaction forces and shall conform to the requirements of the following subparagraphs.

ND-3677.2 Piping to Pressure Relieving Safety Devices

(a) Piping that connects a pressure relief device to a piping system shall comply with all the requirements of the Class of piping of the system which it is designed to relieve.

(b) There shall be no intervening stop valves between systems being protected and their protective device or devices, except as provided for in ND-7142.

ND-3677.3 Discharge Piping From Pressure Relieving Safety Devices

(a) Discharge piping from pressure relief devices shall comply with the requirements of the Class of piping applicable to the conditions under which it operates.

(b) There shall be no intervening stop valves between the protective device or devices and the point of discharge, except as provided for in ND-7142.

(c) When discharging directly to the atmosphere, discharge shall not impinge on other piping or equipment and shall be directed away from platforms and other areas used by personnel.

(d) It is recommended that individual discharge lines be used, but if two or more reliefs are combined:

(1) the discharge piping shall be designed with sufficient flow area so as not to affect operation of the relief devices, and

(2) in no case shall the area of such common lines be less than the combined area of all lines discharging into it.

(e) Discharge lines from pressure relieving safety devices within the scope of this Subarticle shall be designed to facilitate drainage.

(f) When the umbrella or drip pan type of connection is used, the discharge piping shall be so designed as to prevent binding due to expansion movements. Drainage shall be provided to remove water collected above the safety valve seat.

ND-3678 Temporary Piping Systems

Prior to service of piping systems and associated equipment, certain temporary piping may be installed to accommodate cleaning by blowing out with steam or air, or by acid or caustic fluid circulation, or other flushing methods. Such temporary piping shall be designed to safeguard against rupture or other failure which could become a hazard to health or safety.

ND-3690 DIMENSIONAL REQUIREMENTS FOR PIPING PRODUCTS

ND-3691 Standard Piping Products

Dimensions of standard piping products shall comply with the standards and specifications listed in Table ND-3132-1.

ND-3692 Nonstandard Piping Products

The dimensions of nonstandard piping products shall be such as to provide strength and performance equivalent to standard products, except as permitted in ND-3641.

ND-3700 ELECTRICAL AND MECHANICAL PENETRATION ASSEMBLIES

ND-3720 DESIGN RULES

(a) The design of the pressure retaining portion of electrical and mechanical penetration assemblies shall be the same as for vessels (ND-3300).

(b) For closing seams in electrical and mechanical penetration assemblies meeting the requirements of ND-4730(c), the closure head shall meet the requirements of ND-3325 using a factor $C = 0.20$. The fillet weld shall be designed using an allowable stress of 0.5S.

ND-3800 DESIGN OF ATMOSPHERIC STORAGE TANKS

ND-3810 GENERAL REQUIREMENTS

ND-3811 Acceptability

The requirements for acceptability of atmospheric storage tanks are given in the following subparagraphs.

ND-3811.1 Scope.

The design rules for atmospheric storage tanks cover vertical cylindrical flat bottom above

Page 171

ground²⁷ welded tanks at atmospheric pressure. The tanks may contain liquids such as refueling water, condensate, boroated reactor coolant, or liquid radioactive waste. Such tanks may be within building structures, depending upon the liquid to be contained, or they may be above grade exposed to atmospheric conditions.

ND-3811.2 Design Requirements.

The design rules for atmospheric storage tanks shall conform to the design requirements of ND-3100 and ND-3300, except as they may be modified by the requirements of this Subarticle. The joint efficiency E shall be based on the requirements of ND-3352. The specific design requirements shall be stipulated in the Design Specifications.

ND-3812 Design Report

The manufacturer of a storage tank conforming to the design requirements of this Subarticle is required to provide a Design Report as part of his responsibility of achieving structural integrity of the tank. The Design Report shall be certified when required by NCA-3550.

ND-3820 DESIGN CONSIDERATIONS

ND-3821 Design and Service Conditions

(a) Conditions shall be identified as Design or Service, and if Service they shall have Level A, B, C, or D Service Limits designated.

(b) The provisions of ND-3110 shall apply.

(c) The stress limits given in ND-3821.5 shall be met.

ND-3821.1 Design Pressure.

The Design Pressure²⁸ shall be atmospheric.

The Design Pressure shall be atmospheric.

ND-3821.2 Design Temperature.

The Design Temperature shall be not greater than 200°F.

ND-3821.3 Loadings.

The requirements of ND-3111 shall be met.

ND-3821.4 Welded Joint Restrictions.

The restrictions given in (a) through (c) below on type and size of joints or welds shall apply.

27 These rules do not limit storage tanks from being installed below grade or below ground, provided the tanks are not subject to external pressure resulting from earth or fill.

28 The limitation of the Design Pressure to atmospheric is not intended to preclude the use of these tanks at vapor pressure slightly above or below atmospheric within the range normally required to operate vent valves. If these pressure or vacuums exceed $\frac{1}{2}$ oz /sq in., especially in combination with large diameter tanks, the forces involved may require special consideration in the design.

TABLE ND-3324.8(b)-1
VALUES OF FACTOR M
Use Nearest Value of L/r ; Interpolation Unnecessary

L/r	1.0	1.25	1.50	1.75	2.00	2.25	2.50	2.75	3.00	3.25	3.50
M	1.00	1.03	1.06	1.08	1.10	1.13	1.15	1.17	1.18	1.20	1.22
L/r	4.0	4.5	5.0	5.5	6.0	6.5	7.0	7.5	8.0	8.5	9.0
M	1.25	1.28	1.31	1.34	1.36	1.39	1.41	1.44	1.46	1.48	1.50
L/r	9.5	10.00	10.5	11.0	11.5	12.0	13.0	14.0	15.0	16.0	16.67
M	1.52	1.54	1.56	1.58	1.60	1.62	1.65	1.69	1.72	1.75	1.77

NOTE:

(1) Maximum ratio allowed by ND-3324.5(d) when L equals the outside diameter of the skirt of the head.

TABLE ND-3821.5-1 DESIGN AND SERVICE LIMITS

(a) Tack welds shall not be considered as having any strength value in the finished structure.

(b) The minimum size of fillet welds shall be in accordance with ND-4246.6.

(c) All nozzle welds shall be in accordance with ND-4246.5.

ND-3821.5 Limits of Calculated Stresses for Design and Service Loadings.

Stress²⁹ limits for Design and Service Loadings are specified in Table ND-3821.5-1. The symbols used in Table ND-3821.5-1 are defined as follows:

σ_m

= general membrane stress, psi. This stress is equal to the average stress across the solid section under consideration. It excludes discontinuities and concentrations, and is produced only by pressure and other mechanical loads.

σ_L

= local membrane stress, psi. This stress is the same as σ_m except that it includes the effect of discontinuities.

σ_b

= bending stress, psi. This stress is equal to the linear varying portion of the stress across the solid section under consideration. It excludes discontinuities and concentrations,

S

and is produced only by pressure and other mechanical loads.
= allowable stress value given in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1, psi. The allowable stress shall correspond to the highest metal temperature at the section under consideration during the loading under consideration.

29 Stress means the maximum normal stress.

Page 172

Typical examples of locations and loadings for which σ_m , σ_L , and σ_b are applicable are shown in Table XIII-1130-1, with σ considered as equivalent to P in Table XIII-1130-1.

ND-3830 BOTTOM DESIGN

ND-3831 Plate Sizes

- (a) All bottom plates shall have a minimum nominal thickness of $\frac{1}{4}$ in. (6 mm) exclusive of any corrosion allowance required by the Design Specifications.
- (b) Bottom plates shall be ordered of sufficient size so that, when trimmed, at least a 1 in. (25 mm) width will project beyond the outside edge of the weld attaching the bottom to the shell plate.
- (c) The type of foundation used for supporting the tank shall be taken into account in the design of the bottom plates and welds. For recommended practice for construction of foundations, see API-650, Appendix B.

ND-3832 Methods of Construction

Bottoms shall be built to either one of the alternative methods of construction given in ND-4246.1.

ND-3833 Shell-to-Bottom Attachment

The requirements for shell-to-bottom attachments are given in ND-4246.2.

ND-3840 SHELL DESIGN

ND-3841 Loads

- (a) Thicknesses shall be computed on the basis of the specific gravity of the stored material, but in no case shall the specific gravity be less than 1.00. The tension in each ring shall be computed 12 in. (305 mm) above the center line of the lower horizontal joint of the course in question. In computing these stresses, the tank diameter shall be taken as the nominal diameter of the bottom course.
- (b) Isolated radial loads on tank shells, such as caused by heavy loads on platforms and elevated walk ways between tanks, shall be distributed by rolled structural sections, plate ribs, or built-up members, preferably in a horizontal position.

ND-3842 Diameters and Thicknesses of Shell Plates

- (a) For method of determining minimum thicknesses³⁰ of shell plates, see ND-3324.3. See ND-2121 for pressure retaining material.
- (b) In no case shall the nominal thickness³¹ of shell plates be less than the following:

Ferrous Material		Aluminum material	
Nominal Tank Diameter, ft ³²	Nominal Thickness, in.	Nominal Tank Diameter, ft ³²	Nominal Thickness, in.
Smaller than 60	$\frac{3}{16}$ ₁	Smaller than 20	$\frac{3}{16}$ ₁

(c) The maximum nominal thickness of tank shell plates shall be $1\frac{1}{2}$ in. (38 mm).

ND-3843 Arrangement of Members

(a) The tank shell shall be designed to have all courses vertical. Unless otherwise specified, abutting shell plates at horizontal joints shall have a common vertical center line of thickness. Vertical joints in adjacent shell courses shall not be in alignment but shall be offset from each other a minimum distance of 6 in.

(b) Except as specified for self-supporting roofs and for tanks having the flanged roof-to-shell detail described in (c) below, tank shells shall be supplied with top angles of not less than the following sizes: tanks 35 ft (10.6 m) and smaller in diameter, $2\frac{1}{2}$ in. $\times$ $2\frac{1}{2}$ in. $\times$ $\frac{1}{4}$ in. (64 mm $\times$ 65 mm $\times$ 6 mm); tanks of more than 35 ft to 60 ft (10.6 m to 18.3 m), inclusive, in diameter, $2\frac{1}{2}$ in. $\times$ $2\frac{1}{2}$ in. $\times$ $\frac{5}{16}$ in. (64 mm $\times$ 64 mm $\times$ 8 mm); tanks larger than 60 ft (18.3 m) in diameter, 3 in. $\times$ 3 in. $\times$ $\frac{3}{8}$ in. (76 mm $\times$ 76 mm $\times$ 10 mm). The outstanding leg of the top angle may extend inside or outside the tank shell.

(c)(1) For tanks not exceeding 35 ft (10.6 m) in diameter and having supported cone roofs, the top edge of the shell may be flanged in lieu of installing a top angle. The radius of bend and the width of the flanged edge shall conform to the details of Fig. ND-4246.3-1 sketch (c).

30 Any specified corrosion allowance for the shell plates shall be added to the calculated thickness.

31 The nominal thickness of shell plates refers to the tank shell as constructed. The thickness specified are based on erection requirements.

32 Nominal tank diameter shall be the center line diameter of the shell plates, unless otherwise stipulated in the Design Specifications.

(2) This construction may be used for any tank having a self-supporting roof if the total cross-sectional area of the junction fulfills the stated area requirements for the top angle construction. No additional member, such as an angle or bar, shall be added to the flanged roof-to-shell detail.

(d) For tanks not exceeding 35 ft (10.6 m) in diameter and having a supported flat roof, the roof plates may be flanged and butt welded to the shell. The flanged tank roof plates shall be butt welded. The inside radius of the knuckle shall not be less than $1.75t$ nor more than $8t$.

ND-3850 ROOF DESIGN

ND-3851 Types of Roofs

The types of roofs are defined in the following subparagraphs.

ND-3851.1 Supported Cone Roof.

A supported cone roof is a roof formed to approximately the surface of a right cone, with its principal support provided by either rafters on girders and columns or rafters on trusses with or without columns.

ND-3851.2 Supported Flat Roof.

A supported flat roof is a roof which is essentially flat, with its principal support provided by either rafters supported by the shell without columns or by rafters in conjunction with girders and trusses with or without columns.

ND-3851.3 Self-Supporting Cone Roof.

A self-supporting cone roof is a roof formed to approximately the surface of a right cone, supported only at its periphery.

ND-3851.4 Self-Supporting Dome Roof.

A self-supporting dome roof is a roof formed to approximately a spherical surface, supported only at its periphery.

ND-3851.5 Self-Supporting Umbrella Roof.

A self-supporting umbrella roof is a modified dome roof so formed that any horizontal section is a regular polygon with as many sides as there are roof plates, supported only at its periphery.

ND-3852 General Roof Design Requirements

ND-3852.1 Loading Requirements.

All roofs and supporting structures shall be designed to support dead load, plus a uniform live load of not less than 25 lb/sq ft (1.2 kPa) of projected area unless otherwise specified, except that tanks installed in an enclosed area, not exposed to the elements, shall be designed to support the dead load plus a uniform live load of not less than 10 lb/sq ft (0.5 kPa).

ND-3852.2 Minimum Plate Thickness.

Roof plates shall have a minimum nominal thickness of $\frac{3}{16}$ in. (4.8 mm). A greater thickness may be required for self-supporting roofs. Any specified corrosion allowance for the plates of self-supporting roofs shall be added to calculated thickness. Any specified corrosion allowance for plates of supported roofs shall be added to the minimum nominal thickness.

ND-3852.3 Minimum Thickness of Supporting Members.

All internal and external structural members shall have a minimum nominal thickness, in any component, of 0.17 in. (4.3 mm).

ND-3852.4 Attachment of Roof Plates.

Roof plates shall be attached to the top angle of the tank in accordance with ND-4246.3. Roof plates of supported roofs shall not be attached to internal supporting members.

ND-3852.5 Welding of Roof Plates

(a) If the continuous fillet weld between the roof plates and the top angle does not exceed $\frac{3}{16}$ in. (4.8 mm) and the slope of the roof at the top angle attachment does not exceed 2 in./ft, the joint may be considered to serve as an emergency venting device which, in case of excessive internal pressure, will fail before failure occurs in the tank shell joints or the shell-to-bottom joint. Failure of the roof-to-shell joint may be accompanied by buckling of the top angle.

(b) Where the weld size exceeds $\frac{3}{16}$ in. (4.8 mm) or where the slope of the roof at the top angle attachment is greater than 2 in./ft, emergency venting devices conforming to the specifications noted in API Standard 2000³³ shall be provided. The Certificate Holder shall provide a suitable tank connection for the device.

(c) Roof plates shall be welded in accordance with ND-4246.4.

ND-3852.6 Allowable Stresses for Ferrous Steel Structures.³⁴

All parts of the structure shall be so proportioned that the sum of the static stresses shall not exceed the values given in (a) through (d) below.

(a) *Tension*

(1) in rolled steel, on net section, 20.0 ksi (138 MPa);

³³ API Standard 2000, 1968 Edition, Venting Atmospheric and Low Pressure Storage Tanks, American Petroleum Institute, 1801 K St., N.W., Washington, D.C. 20036.

³⁴ The decrease in yield stress at Design Temperature shall be taken into account.

(2) in full penetration groove welds on the thinner plate area, 18.0 ksi (124 MPa).

(b) Compression

(1) in rolled steel, where lateral deflection is prevented, 20.0 ksi (138 MPa);

(2) in full penetration groove welds on the thinner plate area, 20.0 ksi (138 MPa);

(3) in columns, on cross-sectional area, ksi:

For L/r not over 120:

$$\left[1 - \frac{(L/r)^2}{34,700} \right] \left[\frac{33 Y}{FS} \right]$$

For L/r over 120 to 131.7, inclusive:

$$\frac{\left[1 - \frac{(L/r)^2}{34,700} \right] \left[\frac{33 Y}{FS} \right]}{1.6 - (L/200r)}$$

For L/r over 131.7:

$$\frac{(149,000 Y)}{(L/r)^2 [1.6 - (L/200r)]}$$

where

L = unbraced length of column, in.

r = least radius of gyration of column, in.

FS = factor of safety

=

$$5/3 + \left[\frac{(L/r)}{350} \right] - \left[\frac{(L/r)^3}{18,300,000} \right]$$

Y = 1.0 for structural sections or tubular sections having t/R values equal to or exceeding 0.015

= $(200/3)(t/R)[2 - (200/3)(t/R)]$ for tubular sections having t/R values less than 0.015

t = thickness of tubular section, in.; $1/4$ in. minimum for main compression members, $3/16$ in. minimum for bracing and other secondary members

R = outside radius of tubular section, in.

For main compression members, the ratio L/r shall not exceed 180. For bracing and other secondary members, the ratio L/r shall not exceed 200.

(c) Bending

(1) in tension and compression on extreme fibers of rolled shapes and built-up members with an axis of symmetry in the plane of loading, where the laterally unsupported length of compression flange is no greater than 13 times its width, the compression flange width-thickness ratio does not exceed 17, and the web depth-thickness ratio does not exceed 70, 22.0 ksi (152 MPa);

(2) in tension and compression on extreme fibers of unsymmetrical members, where the member is supported

laterally at intervals no greater than 13 times its compression flange width, 20.0 ksi;

(3) in tension on extreme fibers of other rolled shapes, built-up members, and plate girders, 20.0 ksi;

(4) in compression on extreme fibers of other rolled shapes, plate girders, and built-up members having an axis of symmetry in the plane of loading, the larger value computed by the following, ksi:

$$20.0 - \frac{0.571}{1000} (l/r)^2$$

or

$$\frac{12,000}{ld / A_f} \leq 20.0$$

where

l = unbraced length of compression flange, in.

r = radius of gyration of section about an axis in the plane of loading, in.

d = depth of section, in.

A_f = area of compression flange, sq in.

Compression on extreme fibers of other unsymmetrical sections, ksi:

$$\frac{12,000}{ld / A_f} \leq 20$$

(d) *Shearing*

(1) in fillet, plug, slot, and partial penetration groove welds across throat area, 13.6 ksi (94 MPa);

(2) on the gross area of the webs of beams and girders, when t is the thickness of the web, in., and h , the clear distance between web flanges, in., is not more than $60t$, or when the web is adequately stiffened, 13.0 ksi (90 MPa);

(3) on the gross area of the webs of beams and girders, if the web is not stiffened so that h is more than $60t$, the greatest average shear V/A shall not exceed, ksi:

$$\frac{19.5}{1 + h^2 / 7200t^2}$$

where

V

V

= the total shear, kips

A

= the gross area of the web, sq in.

ND-3852.7 Allowable Stresses for Aluminum Structures.

All parts of the structure shall be so proportioned that the sum of the static stresses shall

Page 175

not exceed the allowable stresses given in Tables ND-3852.7-1 through ND-3852.7-6.

FIG. ND-3325-1 SOME ACCEPTABLE TYPES OF UNSTAYED FLAT HEADS AND COVERS
The Above Illustrations Are Diagrammatic Only. Other Designs That Meet The Requirements of ND-3325 Are Acceptable.

TABLE ND-3852.7-1 ALLOWABLE TENSILE STRESSES FOR ROOF SUPPORTS

ND-3853 Supported Cone Roofs - General Requirements

ND-3853.1 Slope of Roof.

The slope of roof shall be $\frac{3}{4}$ in./ft (6.25%) or greater. If the rafters are set directly on chord girders, producing slightly varying rafter slopes, the slope of the flattest rafter shall conform to the specified roof slope.

ND-3853.2 Main Supporting Members.

Main supporting members, including those supporting the rafters, may be rolled or fabricated sections or trusses. Although these members may be in contact with the roof plates, the compression flange of a member or the top chord of a truss shall be considered to receive no lateral support from the roof plates and shall be laterally braced, if necessary, by other acceptable methods. The allowable stresses in these members shall be governed by ND-3852.6.

ND-3853.3 Design of Rafters.

Structural members, serving as rafters, may be rolled or fabricated sections but in all cases shall conform with the rules of ND-3852 through ND-3853. Rafters in direct contact with the roof plates applying the loading to the rafters may be considered to receive adequate lateral support from the friction between the roof plates and the compression flanges of the rafters, with the following exceptions:

- (a) trusses and open web joints used as rafters;
- (b) rafters having a nominal depth greater than 15 in. (381 mm);
- (c) rafters having a slope greater than 2 in./ft. (16.7%)

ND-3853.4 Spacing of Rafters.

Rafters shall be spaced so that, in the outer ring, their centers shall not be more than 6.28 ft (1.9 m) apart, measured along the circumference of the tank. Spacing on inner rings shall not be greater than $5\frac{1}{2}$ ft (1.7 m).

ND-3853.5 Roof Columns.

Roof columns shall be made from structural shapes or pipe.

ND-3853.6 Attachment of Rafter Clips and Column Base Clip Guides.

Rafter clips for the outer row of rafters shall be welded to the tank shell. Column base clip guides shall be welded to the tank bottom to prevent lateral movement of column bases. All other structural attachments shall be either bolted or welded.

ND-3853.7 Welding of Roof Plates.

Roof plates shall be welded in accordance with ND-4246.4. The size of the roof-to-top angle weld shall be $\frac{3}{16}$ in. (4.8 mm) or smaller.

ND-3854 Supported Flat Roofs

ND-3854.1 General Requirements.

The use of supported flat roofs shall be limited to tanks having diameters not greater than 35 ft (10.6 mm). The design of supported flat roofs shall be in accordance with ND-3853 except as noted below.

ND-3854.2 Main Supporting Members

- (a)

= combined cross-sectional area of roof plate, shell plate, and top shell angle, sq in.

NOTES:

- (1) L_b = length of beam between points at which the compression flange is supported against movement or length of cantilever beam from free end to point at which the compression flange is supported against lateral movement, in.
- (2) r_y = radius of gyration of beam about axis parallel to web, in. For beams that are unsymmetrical about the horizontal axis, r_y should be calculated as though both flanges were the same as the compression flange.
- (3) Rafter with compression flanges in direct contact with the roof plates which they support may be considered to have adequate and continuous lateral support; therefore, allowable stresses for zero length may be used.
- (4) These allowable stresses apply to all material welded with 5556 or 5356 filler alloy for temperatures not exceeding 150°F, and to material $\frac{3}{8}$ in. or less in thickness welded with 4043 or 5554 filler alloy. For thicker material welded with 4043 or 5554 filler alloy, these allowable stresses shall be reduced by multiplying them by 0.8. Allowable stresses not marked with a number in parentheses apply to material welded with either 5556 or 5356 filler alloy for temperatures not exceeding 150°F, or either 4043 or 5554 alloy.
- (5) These slenderness limits apply to all material welded with 5556 or 5356 filler alloy for temperatures not exceeding 150°F, and to material $\frac{3}{8}$ in. or less in thickness welded with 4043 or 5554 filler alloy. For thicker material welded with 4043 or 5554 filler alloy, these slenderness limits must be adjusted to correspond to the reduced values of maximum allowable stresses indicated in Note (4) above.

TABLE ND-3852.7-4

6063-T6	To 100	8.5	$\frac{h}{t} = 19$	$9.5 - 0.054 \frac{h}{t}$	$\frac{h}{t} = 79$	$\frac{33,000}{(h/t)^2}$	4	$\frac{h}{t} = 91$	$\frac{33,000}{(h/t)^2}$
	150	8.5	$\frac{h}{t} = 13$	$9.2 - 0.052 \frac{h}{t}$	$\frac{h}{t} = 79$	$\frac{32,000}{(h/t)^2}$	3.6	$\frac{h}{t} = 94$	$\frac{32,000}{(h/t)^2}$
6063-T6	200	8	$\frac{h}{t} = 16$	$8.8 - 0.049 \frac{h}{t}$	$\frac{h}{t} = 80$	$\frac{31,000}{(h/t)^2}$	3.5	$\frac{h}{t} = 94$	$\frac{31,000}{(h/t)^2}$

NOTES:

(1) h = clear height of web, in.(2) t = thickness of web, in.(3) These allowable stresses apply to all material welded with 5556 or 5356 filler alloy for temperatures not exceeding 150°F, and to material $\frac{3}{8}$ in. or less in thickness welded with 4043 or 5554 filler alloy. For thicker material welded with 4043 or 5554 filler alloy, these allowable stresses shall be reduced by multiplying them by 0.8. Allowable stresses not marked with a number in parentheses apply to material welded with either 5556 or 5356 filler alloy for temperatures not exceeding 150°F, or either 4043 or 5554 alloy.(4) These slenderness limits apply to all material welded with 5556 or 5356 filler alloy for temperatures not exceeding 150°F, and to material $\frac{3}{8}$ in. or less in thickness welded with 4043 or 5554 filler alloy. For thicker material welded with 4043 or 5554 filler alloy, these slenderness limits must be adjusted to correspond to the reduced values of maximum allowable stresses indicated in Note (3) above.

TABLE ND-3852.7-4 ALLOWABLE SHEAR STRESSES FOR ROOF SUPPORTS

TABLE ND-3852.7-5
ALLOWABLE SHEAR AND TENSION STRESSES FOR
BOLTS FOR ROOF SUPPORTS
Bolts Shall Not be Welded

Description of Bolt	Allowable Stress, ksi		
	Maximum Temperature, °F		
	To 100	150	200
2024-T4 bolts	Shear		
	16	15	14.5
	Tension		
	26	26	25
2024-T4 bolts 6061-T6 bolts	18	17	17

TABLE ND-3852.7-5 ALLOWABLE SHEAR AND TENSIONS STRESSES FOR BOLTS FOR ROOF SUPPORTS

D	= nominal diameter of tank shell, ft
θ	= angle of cone elements with the horizontal, deg
f	= tensile working stress for the material of the roof plates, shell plates, or top shell angle, whichever is the least value, at the service temperature, psi
P	= dead load of roof, plus the live load, lb/sq ft
R	= radius of curvature of roof, ft
t_r	= nominal thickness of roof plates, in.

TABLE ND-3852.7-6
ALLOWABLE BEARING STRESSES FOR
BOLTS FOR ROOF SUPPORTS
Bolts Shall Not be Welded

Alloy and Temper	Maximum Temperature, °F	Allowable Stress, ksi	
		Cross Sections Farther Than 1.0 in. From Any Weld	Cross Sections Within 1.0 in. of a Weld
		Bolts [Note (1)]	
6061-T6	To 100	34	18 [Note (2)]
	150	33	18 [Note (2)]
	200	32	18 [Note (2)]
6063-T6	To 100	24	10
	150	23	9.5
	200	22	9

NOTES:

- (1) These values apply for a ratio of edge distance to bolt diameter of 2 or more. For smaller ratios, multiply these allowable stresses by the ratio (edge distance)/(twice the bolt diameter).
- (2) These allowable stresses apply to all material welded with 5556 or 5356 filler alloy for temperatures not exceeding 150°F, and to material $\frac{3}{8}$ in. or less in thickness welded with 4043 or 5554 filler alloy. For thicker material welded with 4043 or 5554 filler alloy, these allowable stresses shall be reduced by multiplying them by 0.8.

TABLE ND-3852.7-6 ALLOWABLE BEARING STRESSES FOR BOLTS FOR ROOF SUPPORTS

ND-3855.2 Design Requirements for Ferrous Material.

Self-supporting cone roofs shall conform to the requirements³⁵ of (a) through (c) below.

(a) Slope

Maximum $\theta=37$ deg (tangent=9:12)

Minimum $\sin \theta=0.165$ [slope 2 in./ft (16.7%)]

(b) Plate Thickness

(1) Minimum $t_r = \frac{D}{400 \sin \theta}$ but not less than $\frac{3}{16}$ in.

Maximum $t_r = \frac{1}{2}$ in.

(2) Self-supporting roofs having the roof plates stiffened by sections welded to the plates need not conform to the minimum thickness requirements but shall be not less than $\frac{3}{16}$ in.

(c) Top Angle to Roof-to-Shell Joint. The cross-sectional area of the top angle, in square inches, plus the cross-sectional areas of the shell and roof plates within a distance of 16 times their thicknesses, measured from their most remote point of attachment to the top angle, shall equal or exceed:

$$\frac{D^2}{3000 \sin \theta}$$

ND-3855.3 Design Requirements for Aluminum Material.

Self-supporting cone roofs shall conform to the requirements of (a) through (c) below.

(a) Slope

Minimum $\sin \theta=0.165$ [slope 2 in./ft (16.7%)]

Maximum $\theta=37$ deg (tangent=9:12)

(b) Plate Thickness

$$t_r = \frac{D}{1414 \sin \theta} \sqrt{P}$$

but not less than $\frac{3}{16}$ in. nominal.

(c) *Top Angle to Roof-to-Shell Joint.* The cross-sectional area of the top angle, in square inches, plus the cross-sectional areas of the shell and roof plates within a distance of 16 times their thicknesses, measured from their most remote point of attachment to the top angle, shall equal or exceed:

$$\text{Minimum } A_t = \frac{PD^2}{8f \sin \theta}$$

³⁵ The Formulas applying to self-supporting roof provide for a uniform live load of 25 lb/ft².

ND-3856 Self-Supporting Dome and Umbrella Roofs

ND-3856.1 Nomenclature.

See ND-3855.1 for nomenclature.

ND-3856.2 Design Requirements for Ferrous Material.

Self-supporting dome and umbrella roofs shall conform to the requirements³² of (a) through (c) below.

(a) Radius of Curvature

$R = D$ unless otherwise specified

Minimum $R = 0.80D$

Maximum $R = 1.2D$

(b) Plate Thickness

(1) Minimum $t = R/200$ but not less than $\frac{3}{16}$ in.

Maximum $t = \frac{1}{2}$ in.

(2) Self-supporting roofs having the roof plates stiffened by sections welded to the plates need not conform to the minimum thickness requirements but shall be not less than $\frac{3}{16}$ in.

(c) *Top Angle to Roof-to-Shell Joint.* The cross-sectional area of the top angle, in square inches, plus the cross-sectional areas of the shell and roof plates within a distance of 16 times their thicknesses, measured from their most remote point of attachment to the top angle, shall equal or exceed:

$$\frac{DR}{1500}$$

ND-3856.3 Design Requirements for Aluminum Material.

Self-supporting dome and umbrella roofs shall conform to the requirements of (a) through (c) below.

(a) Radius of Curvature

Minimum $R = 0.80D$

Maximum $R = 1.2D$

(b) Plate Thickness

$$t_r = \frac{R}{707} \sqrt{P}$$

but not less than $\frac{3}{16}$ in. nominal.

(c) *Top Angle to Roof-to-Shell Joint.* The cross-sectional area of the top shell angle, in square inches, plus the cross-sectional areas of shell and roof plates within a distance of 16 times their thicknesses, measured from their most remote point of attachment to the top shell angle, shall equal or exceed:

$$t_r = \frac{R}{707} \sqrt{P}$$

ND-3856.4 Top Angle Attachment for Self-Supporting Roofs

(a) The top angle sections for self-supporting roofs shall meet the requirements of ND-4246.6(d). Joint efficiency factors need not be applied.

(b) For self-supporting roofs, the edges of the roof plates may be flanged horizontally to rest flat against the top angle to improve welding conditions.

ND-3860 TANK CONNECTIONS AND APPURTENANCES

ND-3861 Roof Manholes

Roof manholes shall conform to Fig. ND-3861-1 and Table ND-3861-1, except that alternative designs which provide equivalent strength are permissible if agreed to by the Owner or his designee.

ND-3862 Roof Nozzles

(a) Flanged roof nozzles shall conform to Fig. ND-3862(a)-1 and Table ND-3862(a)-1. Threaded nozzles shall conform to Fig. ND-3862(a)-2 and Table ND-3862(a)-2. Alternative designs for flanged roof nozzles and threaded nozzles can be used, provided they are of equivalent strength and are agreed to by the Owner or his designee.

(b) Roof nozzles are not intended to take loads from pipe reactions. Earthquake loadings need not be considered.

ND-3863 Bottom Outlet Elbows

Bottom outlet elbows shall conform to Fig. ND-3863-1 and Table ND-3863-1.

ND-3864 Threaded Connections

Threaded piping connections shall be female and shall be tapered. The threads shall conform to the requirements for taper pipe threads included in ANSI B1.20.1.

ND-3865 Platforms, Walkways, and Stairways

Platforms, walkways, and stairways shall be in accordance with Tables ND-3865-1 through ND-3865-3.

Page 181

**TABLE ND-3861-1
ROOF MANHOLES**
See Fig. ND-3861-1 All Dimensions Are in Inches.

Size of Manhole	Diameter of Neck I.D.	Diameter of Cover Plate D_C	Diameter of Bolt Circle D_B	Number of Bolts	Diameter of Gasket		Diameter of Hole in Roof Plate or Reinforcing Plate D_P	O.D. of Reinforcing Plate D
					I.D.	O.D.		
20	20	26	23½	16	21½	26	20⅝	42
24	24	30	27½	20	25½	30	24⅝	46

TABLE ND-3861-1 ROOF MANHOLES

ND-3866 Nozzle Piping Transitions

The stress limits of Table ND-3821.5-1 shall apply to all portions of nozzles which lie within the limits of reinforcement given in ND-3334, except as provided in ND-3867. Stresses in the extension of any nozzle beyond the limits of reinforcement shall be subject to the stress limits of ND-3600.

ND-3867 Consideration of Standard Reinforcement

(a) Where a nozzle-to-shell junction is reinforced in accordance with the rules of ND-3334, the stresses in this region due to internal pressure may be considered to satisfy the limits of Table ND-3821.5-1. Under these conditions, no analysis is required to demonstrate compliance for pressure induced stresses in the nozzle region.

(b) Where external piping loads are to be designed for, membrane plus bending stresses due to these loads shall be calculated in the nozzle, and membrane stresses shall be calculated in the local nozzle-to-shell region. These stresses, in conjunction with pressure induced stresses, shall meet the limits of Table ND-3821.5-1 for $(\sigma_m \text{ or } \sigma_L) + \sigma_b$. In this case, the pressure induced stresses in the $(\sigma_m \text{ or } \sigma_L) + \sigma_b$ category may be assumed to be no greater than the limit specified for σ_m in Table ND-3821.5-1, for a given loading.

ND-3900 DESIGN OF 0-15 psi (0-103 kPa) STORAGE TANKS

ND-3910 GENERAL REQUIREMENTS

ND-3911 Acceptability

36 These rules do not limit storage tanks from being installed below grade or below ground, provided the tanks are not subject to external pressure resulting from earth or fill.

ND-3911.1 Scope.

The design rules for 0-15 psi (0-103 kPa) storage tanks shall cover above ground³⁶ welded storage tanks. These tanks may contain liquids or gases such as refueling water, condensate, borated reactor coolant, or radioactive waste. Such tanks are normally located within building structures.

ND-3911.2 Design Requirements

(a) The design requirements for 0-15 psi (0-103 kPa) storage tanks shall conform to the design rules of ND-3100 and ND-3300 except where they are modified by the requirements of this Subarticle. The joint efficiency E shall be based on the requirements of ND-3352. The specific design requirements shall be stipulated by the Design Specifications.

(b) The total liquid capacity of a tank shall be defined as the total volumetric liquid capacity below the high liquid design level. The nominal liquid capacity of a tank shall be defined as the total volumetric liquid capacity between the plane of the high liquid design level and the elevation of the tank grade immediately adjacent to the wall of the tank or such other low liquid design level as the Certificate Holder shall stipulate.

ND-3912 Design Report

The Certificate Holder of a storage tank conforming to the design requirements of this Subarticle is required to provide a Design Report as part of his responsibility of achieving structural integrity of the tank. The Design Report shall be certified when required by NCA-3550.

ND-3920 DESIGN CONSIDERATIONS

ND-3921 Design and Service Loadings

(a) Loadings shall be identified as Design or Service, and, if Service, they shall have Level A, B, C, or D Service Limits designated (NCA-2142).

(b) The provisions of ND-3110 shall apply.

(c) The stress limits of ND-3921.8 shall be met.

FIG. ND-3863-1 WELDED BOTTOM OUTLET ELBOW

TABLE ND-3865-1

PLATFORMS AND WALKWAYS

1. All parts to be made of metal.
 2. Width of floor level (min.): 24 in.
 3. Flooring to be made of grating or nonslip material.
 4. Height of top railing above floor¹: 42 in.
 5. Height of toeboard (min.): 3 in.
 6. Space between top of floor and bottom of toeboard (max.): $\frac{1}{4}$ in.
 7. Height of midrail: approximately one-half the distance from top of walkway to top of railing.
 8. Distance between railing posts (max.): 96 in.
 9. The completed structure shall be capable of supporting a moving concentrated load of 1000 lb, and the handrailing structure shall be capable of withstanding a load of 200 lb applied in any direction at any point on the top rail.
 10. Handrails to be on both sides of platform, discontinuing where necessary for access.
 11. At handrail openings, any space between tank and platform wider than 6 in. should be floored.
 12. Tank runways, which extend from one part of a tank to any part of an adjacent tank, or to ground or other structure, shall be so supported as to permit free relative movement of the structures joined by the runway. This may be accomplished by firm attachment of runway to one tank, but with a slip joint at point of contact between runway and other tank. This is to permit either tank to settle or be disrupted by an explosion without endangering the other.
-

NOTE:

- (1) Handrail height as required by ANSI specifications. This height is mandatory in some states.

TABLE ND-3865-1 PLATFORMS AND WALKWAYS

37 Whenever a tank is to be operated with liquid levels which at no time reach the top of the roof, but is to be filled to the very top of the roof during the hydrostatic test, it shall be designed for both of these maximum liquid level conditions, using in each case the density of the liquid employed. If a tank is not designed to be filled to the very top of the roof, overfill protection is required.

38 A suitable margin shall be allowed between the pressure at which the relief valves are set, so as to allow for the increases in pressure caused by variations in the temperature or gravity of the liquid contents of the tank and other factors affecting the pressure in the gas or vapor space.

39 The partial vacuum shall be greater than that at which the vacuum relief valves are set to open.

ND-3921.1 Design Pressure

(a) The walls of the gas or vapor space and other components of the tank above the maximum liquid level³⁷ at the top of the tank shall be designed for a pressure not less than that at which the pressure relief valves are to be set³⁸ and for the maximum partial vacuum which can be developed in such space³⁹ when the inflow of air, gas, or vapor through the vacuum relief valves is at its maximum specified rate. The maximum positive gage pressure for which this space is designed shall be understood to be the nominal pressure rating for the tank and shall not exceed 15 psi (103 kPa).

TABLE ND-3865-2 STAIRWAYS

1. All parts to be made of metal.
2. Width of stairs (min.): 24 in.
3. Angle¹ of stairway with a horizontal line (max.): 50 deg
4. Width of stair treads (min.): 8 in. [The run (defined as the horizontal distance between the noses of successive tread pieces) and the rise of stair treads shall be such that the sum of twice the rise, plus the run, shall be not less than 24 in. nor more than 26 in. Rises shall be uniform throughout the height of the stairway.]
5. Treads to be made of grating or nonslip material.
6. Top railing shall join platform handrail without offset, and the height measured vertically from tread level at nose of tread shall be 30 to 34 in.
7. Distance between railing posts (max.) measured along slope of railing: 96 in.
8. The completed structure shall be capable of supporting a moving concentrated load of 1000 lb, and the handrailing structure shall be capable of withstanding a load of 200 lb applied in any direction at any point on the top rail.
9. Handrails shall be on both sides of straight stairs; also, handrails shall be on both sides of circular stairs when the clearance between tank shell and stair stringer exceeds 8 in.
10. Circumferential stairways should be completely supported on the shell of the tank, and ends of the stringers should be clear of the ground.

NOTE:

- (1) It is recommended that the same angle be employed for all stairways in a tank group or plant area.

TABLE ND-3865-2 STAIRWAYS

(b) All portions of the tank at levels below maximum liquid level shall be designed for the most severe combination of gas pressure, partial vacuum, and static liquid head.

ND-3921.2 Design Temperature.

The Design Temperature shall not be greater than 200°F (93°C).

ND-3921.3 Tank Shape.

Tank walls shall be so shaped as to avoid any pockets on the inside where gases may become trapped when the liquid level is being raised or pockets on the outside where rainwater may collect.

ND-3921.4 Loadings.

See ND-3111 for loadings to be considered.

ND-3921.5 Corrosion Allowance.

When corrosion is expected on any part of the tank wall or on any external or internal supporting or bracing members upon which the safety of the completed tank depends, additional metal thickness in excess of that required by the design computations shall be provided or some satisfactory method of protecting these surfaces from

Page 187

corrosion shall be employed. Such added thickness need not be the same for all zones of exposure inside and outside of the tank.

TABLE ND-3865-3 STAIRWAY RISE, RUN, AND ANGLE RELATIONSHIPS

ND-3921.6 Linings.

When corrosion resistant linings are attached to any element of the tank wall, including nozzles, their thickness shall not be included in the computation for the required wall thickness.

ND-3921.7 Welded Joint Restrictions.

The restrictions on type and size of joints or welds given in (a) through (c) below shall apply.

(a) Tack welds shall not be considered as having any strength value in the finished structure.

(b) The weld joint requirements shall be as given in ND-4247.

(c) All nozzle welds shall be in accordance with ND-4244.

40.Stress means the maximum normal stress.

ND-3921.8 Limits of Calculated Stresses for Design and Service Loadings.

Stress⁴⁰ limits for Design and Service Loadings are specified in Table ND-3921.8-1. The symbols used in Table ND-3921.8-1 are defined as follows:

σ_m	= general membrane stress, psi. This stress is equal to the average stress across the solid section under consideration. It excludes discontinuities and concentrations, and is produced only by pressure and other mechanical loads.
σ_L	= local membrane stress, psi. This stress is the same as σ_m , except that it includes the effect of discontinuities.
σ_b	= bending stress, psi. This stress is equal to the linear varying portion of the stress across the solid section under consideration. It excludes
	discontinuities and concentrations, and is produced only by pressure and other mechanical loads.
S	= allowable stress value given in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1, psi. The allowable stress shall correspond to the highest metal temperature at the section under consideration during the loading under consideration.

**TABLE ND-3921.8-1
DESIGN AND SERVICE LIMITS
FOR STEEL TANKS**

Service Limit	Stress Limits ^{1,2}
Design and Level A	$\sigma_m \leq 1.0S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.5S$
Level B	$\sigma_m \leq 1.10S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.65S$
Level C	$\sigma_m \leq 1.5S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 1.8S$
Level D	$\sigma_m \leq 2.0S$ $(\sigma_m \text{ or } \sigma_L) + \sigma_b \leq 2.4S$

NOTES:

- (1) See ND-3921.8 for definitions of symbols.
- (2) These limits do not take into account either local or general buckling which might occur in thin wall vessels.

TABLE ND-3921.8-1 DESIGN AND SERVICE LIMITS FOR STEEL TANKS

Typical examples of locations and loadings for which σ_m , σ_L , and σ_b are applicable are shown in Table XIII-1130-1 with σ in Table ND-3921.8-1 considered as equivalent to P in Table XIII-1130-1.

ND-3922 Maximum Allowable Stress Values for Tanks

ND-3922.1 Nomenclature.

The various symbols used for stresses are defined as follows:

t	= thickness, in., of sidewalls, roof, or bottom, including corrosion allowance
c	= allowance for corrosion, in.
R	= radius of the wall, in.
R	= radius of curvature of the tank wall in a meridian plane, in.

R_2	= length, in., of the normal to the tank wall measured from the wall of the tank to its axis of revolution
T_1	= meridional unit force in the wall of the tank, lb/in. of latitudinal arc
T_2	= latitudinal unit force in the wall of the tank, lb/in. of meridional arc
S_{ts}	= maximum allowable stress for simple tension, psi (Tables 1A, 1B, and 3, Section II, Part D, Subpart 1)
S_{cs}	= maximum allowable longitudinal compressive stress, psi, for a cylindrical wall acted upon by an axial load with neither a tensile nor a compressive force acting concurrently in a circumferential direction, and determined in accordance with ND-3922.3(a) for the thickness-radius ratio involved
S_{ta}	= allowable tensile stress, psi, which is lower than S_{ts} because of the presence of a coexistent compressive stress perpendicular to it
S_{ca}	= allowable compressive stress, psi, which is lower than S_{cs} because of the presence of a coexistent tensile or compressive stress perpendicular to it
S_{tc}	= computed tensile stress, psi, at the point under consideration
S_{cc}	= computed compressive stress, psi, at the point under consideration
S_t	= general symbol for indicating a tensile stress, psi, which may be either an allowable or computed value, depending on the context in which the symbol is used
S_c	= general symbol for indicating a compressive stress, psi, which may be either an allowable or computed value, depending on the context in which the symbol is used
N	= ratio of the tensile stress S_t to the maximum allowable stress for simple tension S_{ts}
M	= ratio of the compressive stress S_c to the maximum allowable compressive stress S_{cs} (Fig. ND-3922.1-2)

ND-3922.2 Maximum Tensile Stresses.

The maximum tensile stresses in the outside walls of a tank, as determined for any loadings or any concurrent combination of such loadings, shall not exceed the applicable stress values determined in accordance with (a) or (b) below.

(a) If both the meridional and latitudinal unit forces T_1 and T_2 are tensile, or if one of these forces is tensile and the other is zero, the computed tensile stress S_{tc} shall not exceed the applicable value given in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1.

(b) If the meridional unit force T_1 is tensile and the coexistent latitudinal unit force T_2 is compressive, or if T_2 is tensile and T_1 is compressive, the computed tensile stress S_{tc} shall not exceed a value of S_{ta} obtained by multiplying the applicable stress value given in Tables 1A, 1B, and 3, Section II, Part D, Subpart 1 by the appropriate value of N obtained from Fig. ND-3922.1-1 for the value of compressive stress ($S_c = S_{cc}$) and co-related ratio $(t - c)/R$ involved. However, in

For $(t - c)/R$ values less than 0.00667:

$$S_{cs} = 1,800,000(t - c)/R$$

For $(t - c)/R$ values between 0.00667 and 0.0175:

$$S_{cs} = 10,150 + 277,400(t - c)/R$$

For $(t - c)/R$ values greater than 0.0175:

$$S_{cs} = 15,000$$

However, values of S_{cs} calculated as above, but with R taken as equal to R_1 when the compressive unit force under consideration is latitudinal or with R taken as equal to R_2 when the compressive unit force is meridional, form the basis for the rules given in (b), (c), and (d) below which apply to walls of double curvature.

(b) If both the meridional and latitudinal unit forces T_1 and T_2 are compressive and of equal magnitude, the computed compressive stress S_{ce} shall not exceed a value S_{ca} established for the applicable thickness-radius as follows.

Page 190

Page 191

GENERAL NOTES:

- (1) Hatched area represents overlapping of the reinforcement limits.
- (2) Each cross-section indicated by a straight line a-a must be investigated for adequacy of reinforcement.
- (3) Heavy circles represent openings, and light circles represent limits of reinforcement.

FIG. ND-3335.2-1 ARRANGEMENT OF MULTIPLE OPENINGS

FIG. ND-3922.1-2 REDUCTION OF DESIGN STRESSES REQUIRED TO ALLOW FOR BIAXIAL STRESSES OF OPPOSITE SIGN

For $(t - c)/R$ values less than 0.00667:

$$S_{ca} = 1,000,000(t - c)/R$$

For $(t - c)/R$ values between 0.00667 and 0.0175:

$$S_{ca} = 5,650 + 154,200(t - c)/R$$

For $(t - c)/R$ values greater than 0.0175:

$$S_{ca} = 8,340$$

(c) If both the meridional and latitudinal unit forces T_1 and T_2 are compressive but of unequal magnitude, both the larger and the smaller computed compressive stresses shall be limited to values which satisfy the following requirements:⁴³

$$\frac{(\text{larger stress}) + 0.8 (\text{smaller stress})}{S_{cs} \text{ determined using } R \text{ for the larger unit force}} \leq 1.0$$

$$\frac{1.8 (\text{smaller stress})}{S_{cs} \text{ determined using } R \text{ for the smaller unit force}} \leq 1.0$$

(d) If the meridional unit force T_1 is compressive and the coexistent unit force T_2 is tensile or if T_2 is compressive and T_1 is tensile, the computed compressive stress S_{cc} shall not exceed a value of S_{ca} determined from Fig. ND-3922.1-1 by entering the computed value of N and the value of $(t - c)/R$ associated with the compressive unit stress and by reading the value of S_c which corresponds to that point. Such value of S_c will be the limiting value of S_{ca} for the given conditions. Section F.1 of Appendix F of API 620, Feb. 1970 Ed. gives examples illustrating the determination of allowable compressive stress values S_{ca} .

(e) The allowable compressive stresses previously specified in this subparagraph are predicated on butt welded construction. If one or more of the main joints across which the compressive force acts are of the lap welded type, the allowable compressive stress shall be determined as above except that the maximum compressive stress shall be subject to the limitations of ND-3933.1 and the applicable joint efficiency.

⁴³ In these expressions if the unit force is latitudinal, R shall be considered to be R_1 and, if meridional, R shall be considered as equal to R_2 .

ND-3922.4 Maximum Shear Stresses.

The maximum shear stresses in welds used for attaching man ways, nozzles, reinforcements, or other attachments to

the walls of a tank, and in sections of manway or nozzle necks serving as reinforcement attachment, shall not exceed 80% of the applicable maximum allowable tensile stress value S_{ts} .

ND-3923 Maximum Allowable Stress Values for Structural Members

ND-3923.1 General Stress Limits.

Subject to the provisions of ND-3923.2(c) the maximum stresses in internal or external diaphragms, webs, trusses, columns, and other framing, as determined for any loadings shall not exceed the applicable allowable stresses given in Table ND-3923.1-1.

ND-3923.2 Slenderness Ratio Limits.

The slender ness ratio (i.e., the ratio of the unbraced length l to the least radius of gyration r) for structural members in compression and for tension members other than rods shall not exceed the following values, except as provided in (a) below.

	Maximum l/r
For main compression members	120
For bracing and other secondary members in compression	200
For main tension members	240
For bracing and other secondary members in tension	300

(a) The slenderness ratio of main compression members inside of a tank may exceed 120, but not 200, provided the member is not ordinarily subject to shock or vibration loads and the unit stress under full Design Loadings does not exceed the following fraction of the stress value given in Table ND-3923.1-1 for the member's actual l/r ratio:

$$f = 1.6 - \frac{1}{200r}$$

(b) The gross and net sections of structural members shall be as determined in (1) through (5) below.

(1) The gross section of a member at any point shall be determined by summing the products of the thickness and the gross width of each element as measured normal to the axis of the member. The net section shall be determined by substituting for the gross width the net width which, in the case of a member having a chain of holes extending across it in any diagonal or zigzag line, shall be computed by deducting from the gross width the sum of the diameters of all

$$\frac{s^2}{4g}$$

s = longitudinal spacing (pitch), in., of any two successive holes
 g = transverse spacing (gage), in., of the same two holes

Pages 193-194

TABLE ND-3923.1-1
 MAXIMUM ALLOWABLE STRESS VALUES FOR STRUCTURAL MEMBERS

	Column 1 For Members Not Subject to Pressure-Imposed Loads, ksi	Column 2 For Internal Members Resisting Pressure, ksi
(a) Tension		
Roller steel, on net section.....	18.0	[Note (1)]
Butt welds, on cross-sectional area in, or at edge of, weld ²	18.0	[Note (1)]
Bolts and other threaded parts, on net area at root of thread.....	18.0	[Note (1)]
(b) Compression		
For axially loaded structural columns, structural bracing, and structural secondary members, on gross section.....	18 $1 + \frac{f^2}{18,000r^2}$ but not to exceed 15	Same values as for Column 1
For axially loaded tubular columns, tubular bracing, and tubular secondary members, on gross section (minimum permissible thickness, $\frac{1}{4}$ in.)	$18.0Y$ $1 + \frac{f^2}{18,000r^2}$ but not to exceed 15 Y	Same values as for Column 1
where f = unbraced length of column, in. r = corresponding least radius of gyration of column, in. R = outside radius of tubular column, in. t = thickness of tubular column, in. Y = unity (1.0) for values of t/R equal to or exceeding 0.015 = $\frac{2}{3}$ (100 t/R)(2 - $\frac{2}{3}$ (100 t/R)), for values of t/R less than 0.015		
Butt welds, on least cross-sectional area in, or at edge of, weld (crushing)	18.0	15.0
Plate girder stiffeners, on gross section	18.0	15.0

TABLE ND-3923.1-1 (CONT'D) MAXIMUM ALLOWABLE STRESS VALUES FOR STRUCTURAL MEMBERS

TABLE ND-3923.1-1 (CONT'D)
MAXIMUM ALLOWABLE STRESS VALUES FOR STRUCTURAL MEMBERS

	Column 1 For Members Not Subject to Pressure-Imposed Loads, ksi	Column 2 For Internal Members Resisting Pressure, ksi
(e) Bearing		
Pins and turned bolts in reamed or drilled holes:		
Load applied to bolt at only one side of member connected	24.0	1.33 (tension value ¹)
Load approximately uniformly distributed across thickness of member connected	30.0	1.67 (tension value ¹)
Unfinished bolts:		
Load applied to bolt at only one side of member connected	16.0	0.9 (tension value ¹)
Load approximately uniformly distributed across thickness of member connected	20.0	1.1 (tension value ¹)

NOTES:

(1) Tables 1A, 1B, and 3, Section II, Part D, Subpart 1.

(2) All values for butt welds in tension or shear shall be multiplied by the applicable joint efficiency. These values are obtained by combining the following: a factor of 80% for shear strength of weld metal; an efficiency factor of approximately 85% for fillet welds or 80% for plug welds and slot welds; and a factor of 100% for perpendicular loading or approximately 75% for parallel loading.

[98]

TABLE ND-3923.1-1 (CONT'D) MAXIMUM ALLOWABLE STRESS VALUES FOR STRUCTURAL MEMBERS

(2) In the case of angles, the gage for holes in opposite legs shall be the sum of the gages from the back of the angle less the thickness.

(3) In determining the net section across plug or slot welds, the weld metal shall not be considered as adding to the net area.

(4) For splice members, the thickness considered shall be only that part of the thickness of the member which has been developed by the welds or other attachments beyond the section considered.

(5) In pin connected tension members other than forged eyebars, the net section across the pinhole transverse to the axis of the member shall not be less than 135%, and the net section beyond the pinhole parallel to the axis of the member shall not be less than 90% of the net section of the body of the member. The net width of a pin connected member across the pinhole transverse to the axis of the member shall not exceed eight times the thickness of the member at the pin, unless lateral buckling is prevented.

(c) External structural or tubular columns and framing subject to stresses produced by a combination of wind and other applicable loads specified in ND-3921.4 may be proportioned for unit stresses 25% greater than those specified in Table ND-3923.1-1, provided the section thus required is not less than that required for all other applicable loads combined on the basis of the unit stresses specified in Table ND-3923.1-1. A corresponding increase may be applied to the allowable unit stresses in the connecting bolts or welds.

ND-3930 DESIGN PROCEDURE

ND-3931 Design of Tank Walls

(a) Free body analyses shall be made at successive levels from the top to the bottom of the tank for the purpose of determining the magnitude and character of the meridional and latitudinal unit forces which will exist in the walls of the tank at critical levels under all the various combinations of gas pressure or partial vacuum and liquid head to be encountered in service which may have a controlling effect on the design. To this end it will sometimes be necessary to make several analyses at a given level of the tank to establish the governing conditions of gas pressure and liquid head for

that level. The thicknesses required in the main walls of the tank shall then be computed by the applicable procedures given in ND-3932.3.

(b) For tanks having points of marked discontinuity in the direction of the meridional tangent, such as occurs at the juncture between a conical or dished roof or bottom and a cylindrical sidewall or at the juncture between a conical reducer and a cylindrical sidewall, the portions of the tank near such points shall be designed in accordance with the provisions of ND-3933.

ND-3932 Design of Sidewalls, Roofs, and Bottoms

ND-3932.1 Nomenclature.

The symbols are defined as follows:

P	$= P_L + P_G$ = total pressure, psi, acting at a given level of the tank under a particular condition of loading
P_L	= pressure resulting from the liquid head at the level under consideration in the tank, psi
P_G	= gas pressure, psi, above the surface of the liquid. The maximum value, a pressure not exceeding 15 psig, is the nominal pressure rating of the tank. P_G is positive except in computations for investigating the ability of a tank to withstand a partial vacuum, where the value is negative.
T_1	= meridional unit force in the wall of the tank at the level under consideration, lb/in. of latitudinal arc. T_1 is positive when in tension.
T_2	= latitudinal unit force in the wall of the tank at the level under consideration, lb/in. of meridional arc. T_2 is positive when in tension. In cylindrical sidewalls the latitudinal unit forces are circumferential unit forces.
R_1	= radius of curvature of the tank wall in a meridian plane, at the level under consideration, in. R_1 is to be considered negative when it is on the opposite side of the tank wall from R_2 except as provided in ND-3932.2(f).
R_2	= length, in., of the normal to the tank wall at the level under consideration, measured from the wall of the tank to its axis of revolution. R_2 is always positive except as provided in ND-3932.2(f).
W	= total weight, lb, of that portion of the tank and its contents either above the level under consideration, as in Fig. ND-3932.1-1 sketch (b), or below such level, as in Fig. ND-3932.1-1 sketch (a) which is treated as a free body in the computations for such level. W shall be given same sign as P when acting in the same direction as the pressure on the horizontal face of the free body, and the opposite sign when acting in the opposite direction.
F	= summation, lb, of the vertical components of the forces in all internal or external ties, braces, diaphragms, trusses, columns, skirts, or other structural devices or supports acting on the free body. F shall be given the same sign as P when

	acting in the same direction as the pressure on the horizontal face of the free body and the opposite sign when acting in the opposite direction.
A_T	= cross-sectional area of the interior of the tank at the level under consideration, sq in.
E	= efficiency, expressed as a decimal, of the weakest joint across which the stress under consideration acts
S_{ts}	= maximum allowable stress for simple tension, psi (Tables 1A, 1B, and 3, Section II , Part D, Subpart 1)
S_{ta}	= allowable tension stress, psi, as required in ND-3922.2(b)
S_{ca}	= allowable compression stress, psi, as required in ND-3922.3
S_{tc}	= computed tension stress, psi, at the point under consideration
S_{cc}	= computed compression stress, psi, at the point under consideration

44 (a) Equation (2) has been derived from a summation of the components, normal to the surface, of the T_1 and T_2 forces acting on a unit area of the tank wall subjected only to a pressure P . To be technically correct, the normal to the surface components of other loads, such as metal, snow, or insulation, should be added to or subtracted from the term P . For the usual internal Design Pressure, these added loads are small compared to the pressure P and can be omitted without significant error. When the pressure P is relatively small including the case of the partial vacuum loading, the other load components can have a substantial effect on the calculated T_2 force and the resultant thickness.

(b) Example F.3.01 in Appendix F of API 620 Feb. 1970 Edition calculates the required roof thicknesses under a small vacuum by considering the metal, insulation, and snow loads in Eqs. (1) through (6). The designer should note that if these loads had been omitted the calculated thicknesses would have been much less than the correct values.

(c) In Eqs. (1), (5), (7), and (10), the term W is intended to include loads, such as metal weight, of significant value. At points away from the vertical center line of the roof, the value of T_2 is required for the thickness calculations of Eqs. (18), (20), and (22) and the value of P in Eqs. (2), (6), and (9) must be modified by the normal components of the added loads for the correct determination of T_2 .

ND-3932.2 Computation of Unit Forces

(a) At each level of the tank selected for free body analysis as specified in ND-3931 (Fig. ND-3932.1-1) and for each condition of gas and liquid loading which must be investigated at such level, the magnitude of the meridional and latitudinal unit forces in the wall of the tank shall be computed from Eqs.⁴⁴ (1) and (2) below, except as provided in ND-3932.6 or ND-3933.

Page 196

Page 197

FIG. ND-3932.1-1 SOME TYPICAL FREE BODY DIAGRAMS FOR CERTAIN SHAPES OF TANKS

FIG. ND-3932.1-1 SOME TYPICAL FREE BODY DIAGRAMS FOR CERTAIN SHAPES OF TANKS

$$T_1 = \frac{R_2}{2} \left(P + \frac{W + F}{A_T} \right) \quad (1)$$

$$T_2 = R_2 \left(P - \frac{T_1}{R_1} \right) \quad (2)$$

$$= R_2 \left[P \left(1 - \frac{R_2}{2R_1} \right) - \frac{R_2}{2R_1} \left(\frac{W + F}{A_T} \right) \right]$$

(1 - 2)

(b) Positive values of T_1 and T_2 indicate tensile forces, and negative values indicate compressive forces.

(c) It will usually be necessary to make such analyses at the level of each horizontal joint in the sidewalls, roof, and bottom of the tank and at any intermediate levels at which the center of curvature changes significantly. Moreover, the maximum total pressure, liquid head plus gas pressure which can exist at a given level will not necessarily be the governing condition for that level; sufficient analyses shall be made at each level to establish that combination of liquid head and gas pressure or partial vacuum which, in conjunction with the allowable tensile and compressive stresses, will control the design at such level. Even though a tank may normally be operated at a fixed height of liquid contents, it shall be made safe for any conditions which might develop in filling or emptying the tank.

(d) The values for a point at a horizontal distance x from the vertical axis of a roof or bottom in which the length of the horizontal semiaxis a is two times the length of the vertical semiaxis b may be determined by multiplying the length a by the factor from Table ND-3932.2(d)-1. Values for ellipsoidal shapes of other proportions shall be calculated from the following equations:

$$R_1 = \frac{b^2}{a^4} \left[\frac{a^4}{b^2} + \left(1 - \frac{a^2}{b^2} \right) x^2 \right]^{3/2} = \frac{b^2 (R_2)^3}{a^4} \quad (3)$$

(3)

$$R_2 = \left[\frac{a^4}{b^2} + \left(1 - \frac{a^2}{b^2} \right) x^2 \right]^{1/2} \quad (4)$$

(4)

(e) Equations (1) and (2) are general formulas applicable to any tank having a single vertical axis of revolution and to any free body which is isolated by a horizontal plane which intersects the walls of the tank in only one circle [ND-3932.2(f)]. For shapes most commonly used, these equations reduce to the simplified equations given in (1) through (3) below for the respective shapes indicated.

TABLE ND-3932.2(d)-1
FACTORS FOR DETERMINING VALUES OF
 R_1 AND R_2 FOR 2:1 ELLIPSIODAL
ROOFS AND BOTTOMS

x/α	$u = R_1/\alpha$	$v = R_2/\alpha$
0.00	2.000	2.000
0.05	1.994	1.998
0.10	1.978	1.993
0.15	1.950	1.983
0.20	1.911	1.970
0.25	1.861	1.953
0.30	1.801	1.931
0.35	1.731	1.906
0.40	1.651	1.876
0.45	1.562	1.842
0.50	1.465	1.803
0.55	1.360	1.759
0.60	1.247	1.709

0.95	0.367	1.137
1.00	0.250	1.000

x = horizontal distance from point in roof or bottom to axis of revolution

α = horizontal semiaxis of elliptical cross section

$R_1 = u\alpha$

$R_2 = v\alpha$

TABLE ND-3932.2(d)-1 FACTORS OF DETERMINING VALUES OF R_1 AND R_2 FOR 2:1 ELLIPSIODAL ROOFS AND BOTTOMS

(1) For a Spherical Tank or Spherical Segment of a Tank. $R_1 = R_2 = R_s$, the spherical radius of the tank or segment, and Eqs. (1) and (2) become:

$$T_1 = \frac{R_s}{2} \left(P + \frac{W + F}{A_T} \right) \quad (5)$$

$$T_2 = R_s P - T_1 \quad (6)$$

(5 - 6)

If the sphere is for gas pressure only and if $(W + F)/A_T$ is negligible as compared with P_G Eqs. (5) and (6) reduce to:

$$(7) T_1 = T_2 = \frac{1}{2} P_G R_s$$

(2) For a Conical Roof or Bottom

$$R_1 = \text{infinity}$$

and

$$R_2 = \frac{R_3}{\cos \alpha}$$

where

R_3

= horizontal radius of the base of the cone at the level under consideration, in.

α

= one-half the included apex angle of the conical roof or bottom

For this condition, Eqs. (1) and (2) reduce to:

$$T_1 = \left(\frac{R_3}{2 \cos \alpha} \right) \left(P + \frac{W + F}{A_T} \right) \quad (8)$$

$$T_2 = \frac{PR_3}{\cos \alpha} \quad (9)$$

(8 - 9)

(3) For Cylindrical Sidewalls of a Vertical Tank. $R_1 = \text{infinity}$ and $R_2 = R_c$ the radius of the cylinder, and Eqs. (1) and (2) become:

$$T_1 = \frac{R_c}{2} \left(P + \frac{W + F}{A_T} \right) \quad (10)$$

$$T_2 = PR_c \quad (11)$$

(10 - 11)

If the cylinder is for gas pressure only and if $W + F/A_T$ is negligible as compared with P_G , Eqs. (10) and (11) reduce to:

$$(12) T_1 = \frac{1}{2} P_G R_c$$

$$(13) T_2 = P_G R_c$$

(f) In the case of a torispherical head shown in Fig. ND-3932.1-1(d), applicable equations for the meridional and latitudinal unit forces in the walls of the segment are as follows:

$$(14) T_1 = (\text{in preparation})$$

$$(15) T_2 = (\text{in preparation})$$

[98]

ND-3932.3 Required Thickness.

The thickness of the tank wall at any given level shall be not less than the largest value of t as determined for the level by the methods prescribed in (a) through (d) below. In addition, provision shall be made by means of additional metal, where needed, for the loadings other than internal pressure or possible partial vacuum enumerated in ND-3921.4, and if the tank walls have points of marked discontinuity in the direction of the meridional tangent, such as occur at the juncture between a conical or dished roof or bottom and a cylindrical sidewall, the portions of the tank near such points shall be designed in accordance with the provisions of ND-3933.

(a) If the unit forces T_1 and T_2 are both positive for the governing combination of gas pressure or partial vacuum and liquid head at a given level of the tank, the larger of the two shall be used for computing the thickness required at such level, as follows:

$$t = \frac{T_1}{S_{ts}E} + c \quad \text{or} \quad t = \frac{T_2}{S_{ts}E} + c \quad (16)$$

(16)

(b) If the unit force T_1 is positive and T_2 is negative for the governing combination of gas pressure or partial vacuum and liquid head at a given level of the tank or if T_2 is positive and T_1 is negative, the thickness of tank wall required for this condition shall be determined by assuming different thicknesses until one is found for which the simultaneous values of the calculated tension stress S_{tc} and the calculated compression stress S_{cc} satisfy the requirements of ND-3922.2 (b) and ND-3922.3(d), respectively. The determination of this thickness will be facilitated by using a graphical solution such as illustrated in Appendix F, Section F.2 of API Standard 620, Feb. 1970 Edition. If the unit force acting in compression does not exceed 5% of the coexistent tensile unit force acting perpendicular to it, the designer may determine the thickness required for this condition by using the method specified in (a) above.

NOTE: The value of the joint efficiency factor E will not enter into this determination unless the magnitude of the allowable tensile stress S_{ta} is governed by the product ES_{ts} as provided in ND-3922.2(b).

(c) If the unit forces T_1 and T_2 are both negative and are of equal magnitude for the governing condition of loading at a given level of the tank, the thickness of tank wall required shall be calculated as follows:

$$t = \frac{T_1}{S_{ca}} + c = \frac{T_2}{S_{ca}} + c \quad (17)$$

(17) where S_{ca} has the appropriate value for the thickness-radius ratio involved, as required in ND-3922.3(b) and (e).

Page 199

(d) If the unit forces T_1 and T_2 are both negative but of unequal magnitude for the governing condition of loading at a given level, the thickness of tank wall required for this condition shall be the largest of those thickness values, calculated by the following procedure, which show a proper correlation with the respective thickness-radius ratios involved in their computation (Steps 2 and 4).

Step 1: Calculate the values of

$$t = \frac{\sqrt{(T' + 0.8T'')R'}}{1342} + c \quad (18)$$

(18)

and

$$t = \frac{\sqrt{T''R''}}{1000} + c \quad (19)$$

(19) using values of T' equal to the larger of the two coexistent unit forces and T'' equal to the smaller of the two unit forces, and taking R' and R'' as equal to R_1 and R_2 , respectively, if the larger unit force is latitudinal; but, conversely, taking R' and R'' as equal to R_2 and R_1 , respectively, if the larger unit force is meridional.

Step 2: Deduct the corrosion allowance from each of the two thicknesses calculated in Step 1 and check the thickness-radius ratio $(t - c)/R$ for each based on the value of R used in Eq. (18) or (19). If both such thickness-radius ratios are less than 0.00667, the larger of the two thicknesses calculated in Step 1 will be the required thickness for the condition under consideration. Otherwise, proceed with Step 3.

Step 3: If one or both thickness-radius ratios determined in Step 2 exceed 0.00667, calculate the values of:

$$t = \frac{T' + 0.8T''}{15,000} + c \quad (20)$$

(20)

and

$$t = \frac{T''}{8340} + c \quad (21)$$

(21)

Step 4: Deduct the corrosion allowance from each of the two thicknesses calculated in Step 3 and check the thickness-radius ratio $(t - c)/R$ for each using a value of R equal to R' as defined in Step 1 in connection with the thickness determined from Eq. (20) and a value of R equal to R'' in connection with the thickness determined from Eq. (21). If both such thickness-radius ratios are greater than 0.0175, the larger of the two thicknesses calculated in Step 3 will be the required thickness for the condition under consideration. Otherwise, proceed with Step 5.

Step 5: If one or more of the thickness-radius ratios determined in Step 2 or Step 4 fall between 0.00667 and 0.0175 and the thickness involved was calculated by Eq. (18) or (20), find a thickness which satisfies the following equation:

$$\frac{10,150 (t - c) + 277,400 (t - c)^2}{R'} = T' + 0.8T'' \quad (22)$$

(22) or, if the thickness involved was calculated by Eq. (19) or (21), find a thickness which satisfies the following equation:

$$\frac{5,650 (t - c) + 154,200 (t - c)^2}{R''}$$

$$= T'' \quad (23)$$

(23)

Step 6: Make a selection of thickness from the values calculated. Calculate the values of S_{cc} for both T_1 and T_2 and check that values of S_{cc} satisfy the requirements of ND-3922.3(c).

NOTE: The procedure described in ND-3932.3(d) is predicated on the assumption that the problem is one in which biaxial compression with unit forces of unequal magnitude is the governing condition. In many cases, however, a tentative thickness will have been established previously by other design considerations and only needs to be checked for the external pressure or partial vacuum condition. In such cases, the problem is greatly simplified because the designer has only to compute the values of S_{cc} for both T_1 and T_2 and then check to see that these values satisfy the requirements of ND-3922.3(c), as specified in Step 6 [see Section F.3 of Appendix F of API Standard 620, Feb. 1970 Edition, for examples illustrating the application of ND-3932.3(a)].

[98]

ND-3932.4 Least Permissible Thickness.

In no event shall the net thickness after fabrication of any plate subject to pressure imposed membrane stresses be less than $\frac{3}{16}$ in., exclusive of corrosion allowance. For tanks having cylindrical sidewalls with diameters from 60 ft up to but not including 120 ft, such thickness for

Page 200

sidewall plates shall not be less than $\frac{1}{4}$ in. exclusive of corrosion allowance.

ND-3932.5 External Pressure Limitations.

The thickness computed by the equations and procedures specified in ND-3932, using a negative value of P_G equal to the partial vacuum for which the tank is to be designed, will ensure stability against collapse for tank surfaces of double curvature in which the meridional radius R_1 is equal to or less than R_2 or does not exceed R_2 by more than a very small amount. Data on the stability of sidewall surfaces of prolate spheroids are lacking, and it is not intended that the formulas and procedures be used for evaluating the stability of such surfaces or of cylindrical surfaces against external pressure. However, cylindrical sidewalls of vertical tanks designed in accordance with these rules for storage of liquids⁴⁵ with the thickness of upper courses no t less than specified in ND-3932.4 for the size of tank involved and with increasing thicknesses from top to bottom as required for the combined gas and liquid loadings may safely be subjected to a partial vacuum in the gas or vapor space not exceeding 1 oz/sq in. (0.4 kPa)⁴⁶ with the operating liquid level in the tank at any stage from full to empty.

ND-3932.6 Special Considerations Applicable to Bottoms Resting Directly on Foundations

(a) *Uplift Considerations.* In the case of tanks with cylindrical sidewalls and flat bottoms, the uplift⁴⁷ from the pressure acting on the underside of the roof must not exceed the weight of the sidewalls plus the weight of that portion of the roof which is carried by the sidewalls when no uplift exists, unless such excess is counteracted by increasing the magnitude

of the downward acting forces. This shall be a matter of agreement between the Certificate Holder and Owner. Similar precautions must be taken with flat bottom tanks of other shapes. All weights used in such calculations shall be based on net thicknesses of the materials, exclusive of corrosion allowance.

45 These rules do not contain provisions in respect to the design of cylindrical sidewalls subject to partial internal vacuum in tanks constructed for storage of gases or vapors alone.

46 The vacuum relief valve or valves shall be set to open at a smaller partial vacuum so that the 1 oz partial vacuum will not be exceeded when the inflow of air or gas through the valves is at its maximum specified rate.

47 If external anchors bolts are used for resisting such uplift, it is recommended that their nominal diameter be not less than 1 in. plus a corrosion of a least $\frac{1}{4}$ in. on the diameter.

48 These forces are computed by the applicable equations in ND-3932.

(b) *Foundation Considerations.* The type of foundation used for supporting the tank shall be taken into account in the design of bottom plates and welds. For recommended practice for construction of foundations, see API Standard 620, Feb. 1970 Edition, Appendix C.

ND-3933 Design of Roof and Bottom Knuckle Regions, and Compression Ring

ND-3933.1 Nomenclature.

The symbols used are defined as follows:

w_h	= width, in., of the roof or bottom plate considered to participate in resisting the circumferential force acting on the compression ring region
w_c	= corresponding width, in., of the participating sidewall plate
t_h	= thickness, in., of the roof or bottom plate at and near the juncture of the roof or bottom and sidewalls, including corrosion allowance
t_c	= corresponding thickness, in., of the cylindrical sidewalls at and near such juncture
R_2	= length, in., of the normal to the roof or bottom at the juncture between the roof or bottom and the sidewalls, measured from the roof or bottom to the tank's vertical axis of revolution
R_c	= horizontal radius, in., of the cylindrical sidewall at its juncture with the roof or bottom
T_1	= meridional unit force in the roof or bottom of the tank at its juncture with the sidewall, lb/in. of circumferential arc
T_2	= corresponding latitudinal unit force in the roof or bottom, lb/in. of meridian arc
T_{2s}	= circumferential unit force ⁴⁸ in the cylindrical sidewall of the tank at its juncture with the roof or bottom, lb/in., measured along an element of the cylinder
α	= angle between the direction of T_1 and a vertical line. In a conical surface it is also one-half of the total vertex angle of the cone.
Q	= total circumferential force, lb acting on a vertical cross section through the compression ring region
A	

A_c	= net area, sq in., of the vertical cross section of metal required in the compression ring region, exclusive of all corrosion allowances
S_{ts}	= maximum allowable stress value for simple tension, psi (Tables 1A, 1B, and 3, Section II, Part D, Subpart 1)
E	= efficiency, expressed as a decimal, of meridional joints in the compression ring region in the event that Q should have a positive value, indicating tension

ND-3933.2 General Requirements.

When the roof or bottom of a tank is a cone or partial sphere and is attached to cylindrical sidewalls, the membrane stresses in the roof or bottom act inward on the periphery of the sidewalls. This results in circumferential compressive forces at the juncture, which shall be resisted either by a knuckle curvature in the roof or bottom or by a limited zone at the juncture of the intersecting roof or bottom plates and sidewall plates, supplemented in some cases by an angle, a rectangular bar, or a ring girder.

ND-3933.3 Requirements for Knuckle Regions

(a) If a curved knuckle is provided, a ring girder or other form of compression ring shall not be used and there shall be no sudden changes in the direction of a meridional line at any point. In addition, the radius of curvature of the knuckle in a meridional plane shall not be less than 6%, and preferably not less than 12%, of the diameter of the sidewalls.⁴⁹ Subject to the provisions of (b) below, the thickness of the knuckle at all points shall satisfy the requirements of ND-3932.

(b) Application of the equations in ND-3932.2 to levels immediately above and below a point where two surfaces of differing meridional curvature have a common meridional tangent, as at the juncture between the knuckle region and the spherically dished portion of a torispherical roof, will result in the calculation of two latitudinal unit forces, differing in magnitude and perhaps in sign, at the same point. The latitudinal unit force at such a point will be between the two calculated values, depending on the geometry of the tank wall in that area.

ND-3933.4 Requirements for Compression Rings

(a) If a curved knuckle is not provided, the circumferential compressive forces shall be resisted by other means in the compression ring region of the tank walls. The zone of the tank walls at the juncture between the roof or bottom and the sidewalls includes that width of plate on each side of the juncture which is considered to participate in resisting these forces [Fig. ND-3933.4(a)-1]. The thickness of the wall plate on either side of the juncture shall not be less than the thickness needed to satisfy the requirements of ND-3932, and the widths of plate making up the compression ring region shall be computed from the following equations:

⁴⁹ Use of a knuckle radius as small as 6% of the sidewall diameter will frequently require an excessively heavy thickness for the knuckle region. The thickness requirements for such region will be found more reasonable if larger knuckle radius is used.

FIG. ND-3933.4(a)-1 COMPRESSION RING REGION

FIG. ND-3933.4(a)-1 COMPRESSION RING REGION

$$w_c = 0.6 \sqrt{R_c(t_c - c)} \quad (25)$$

(24 - 25)

(b) The magnitude of the total circumferential force acting on any vertical cross section through the compression ring region shall be computed as follows:

$$(26) Q = T_2 w_h + T_2 w_c - T_1 R_c \sin \alpha$$

and the net cross-sectional area provided in the compression ring region shall not be less than that found to be required by the following equation:

$$A_c = \frac{Q}{15,000} \quad \text{or} \quad \frac{Q}{S_{ts} E} \quad (27)$$

(27)

depending on whether the value of Q as determined by Eq. (26) is negative⁵⁰ or positive.

50 Because of the discontinuities and other conditions found in a compression ring region, biaxial stress design criteria are not considered applicable for a compressive force determined as in Eq.

(26). Experience has shown that a compressive stress of the order of 15,000 psi, as indicated in Eq. (27), is permissible in this case, provided the requirements of ND-3933.5 are satisfied.

ND-3933.5 Details of Compression Ring Regions

(a) If the force Q is negative, indicating compression, the horizontal projection of the effective compression ring region shall have a width in a radial direction not less than 0.015 times the horizontal radius of the tank wall at the level of the juncture between the roof or bottom and the sidewalls. If such projected width

Page 202

does not meet this requirement, appropriate corrective measures shall be taken as specified in this subparagraph.

(b) Whenever the circumferential force Q determined in accordance with ND-3933.4 is of such magnitude that the area required by Eq. (27) is not provided in a compression ring region with plates of the minimum thicknesses established by

the requirements of ND-3932, or when Q is compressive and the horizontal projection of the width w_h is less than specified in ND-3933.5(a), the compressional ring region shall be reinforced either by thickening the roof or bottom and sidewall plates as required to provide a compressional ring region having the necessary cross-sectional area and width as determined on the basis of the thicker plates,⁵¹ or by adding an angle, a rectangular bar, or a ring girder at the juncture of the roof or bottom and sidewall plates, or by a combination of these alternatives.

(c) Such an angle, bar, or ring girder, if used, may be located either inside or outside of the tank⁵² and shall have a cross section of such dimensions that:

(1) its area makes up the deficiency between the area A_c required by Eq. (27) and the cross-sectional area provided by the compression ring region in the walls of the tank;

(2) the horizontal width of the angle, bar, or ring girder is not less than 0.015 times the horizontal radius R_c of the tank wall at the level of the juncture of the roof or bottom and the sidewalls, except that, when the cross-sectional area to be added in an angle or bar is not more than one-half the total area required by Eq. (27), the width requirement for this member may be disregarded, provided the horizontal projection of the width w_h of participating roof or bottom plates alone is equal to or greater than $0.015R_c$ or, with an angle or bar located on the outside of a tank, the sum of the projection of the width w_h and the horizontal width of the added angle or bar is equal to or greater than $0.015R_c$;

(3) when bracing must be provided as specified in ND-3933.5(h), the moment of inertia of the cross section about a horizontal axis shall be not less than that required by Eq. (28).

51 Note that, unless the effect of the unit forces T_2 and T_3 on the resulting increments in width of participating plate may safely be neglected, the use of thicker plates involves recomputing not only w_h and w but also Q and A for the increased plate thicknesses; hence, the design of the compression ring region in this case resolves into a trial and error procedure.

52 See Fig. ND-3933.5(d)-1 for some acceptable details of construction of compression rings.

(d) When the vertical leg of an angle ring or a vertical flange of a ring girder is located on the sidewall of the tank, it may be built into the sidewall if its thickness is not less than that of the adjoining wall plates. However, if this construction is not used, the leg, edge, or flange of the compression ring next to the tank shall make good contact with the wall of the tank around the entire circumference and, except as provided in (e) below, shall be attached along both the top and bottom edges by continuous fillet welds. These welds shall be of sufficient size to transmit to the compression ring angle, bar, or girder that portion of the total circumferential force Q , assuming, in the case of welds separated by the width of a leg or flange of a structural member as shown in Fig. ND-3933.5(d)-1 sketches (a), (g), and (j), that only the weld nearest the roof or bottom is effective. The part thicknesses and weld sizes in Table ND-4247.6(d)-1 relate to dimensions in the as-welded condition before deduction of corrosion allowances, but all other part thicknesses and weld sizes referred to in this subparagraph relate to dimensions after deduction of corrosion allowance.

(e) If a continuous weld is not needed for strength or as a seal against corrosive elements, attachment welds along the lower edge of a compression ring on the outside of a tank may be intermittent provided:

(1) the summation of their lengths is not less than one-half the circumference of the tank;

(2) the unattached width of tank wall between the ends of welds does not exceed eight times the tank wall thickness exclusive of corrosion allowance;

(3) the welds are of such size as needed for strength but in no case smaller than specified in Table ND-4247.6(d)-1.

(f) The projecting part of a compression ring shall be placed as close as possible to the juncture between the roof or bottom plates and the sidewall plates.

(g) If a compression ring on either the inside or outside of a tank is of such shape that liquid may be trapped, it shall be provided with adequate drain holes uniformly distributed along its length. Similarly, if the shape of a compression ring on the inside of a tank is such that gas would be trapped on the underside thereof when the tank is being filled with liquid, adequate vent holes shall be provided along its length. Where feasible, such drain or vent holes shall be not less than $\frac{3}{4}$ in. diameter.

(h) The projecting part of a compression ring without an outer vertical flange need not be braced, provided the width of such projecting part in a radial vertical plane does not exceed 16 times its thickness. With this exception, the horizontal

part of the compression ring shall be braced at intervals around the circumference of the tank with brackets or other suitable members securely attached to both the ring and the tank wall to prevent such part of the ring from buckling laterally.

Page 203

Page 204

GENERAL NOTES:

- (a) See ND-3350 for limitations concerning locations where various types of welded joints may be used.
- (b) For sketches (j) and (k), dimension B shall not exceed A.

FIG. ND-3933.5(d)-1 PERMISSIBLE DETAILS OF COMPRESSION RING CONSTRUCTION

FIG. ND-3933.5(d)-1 PERMISSIBLE DETAILS OF COMPRESSION RING CONSTRUCTION

When such bracing is required, the moment of inertia of the cross section of the angle, bar, or ring girder about a horizontal axis shall be not less than that calculated to be required by the following equation:⁵³

$$I_1 = \frac{1.44 Q_p R_c^2}{29,000,000 k} = 5 \frac{Q_p R_c^2}{k} \times 10^{-8} \quad (28)$$

(28)

where

I_1

= required moment of inertia, in.⁴, for the cross section of a steel compression ring with respect to a horizontal axis through the centroid of the section, not taking credit for any portion of the tank wall except that, in the case of an angle ring whose vertical leg is attached to or forms a part of the tank wall, the moment of inertia of only the horizontal leg shall be considered, and it shall be figured with respect to a horizontal axis through the centroid of such leg⁵³

Q_p

= that portion of the total circumferential force Q , lb, [Eq. (26)] which is carried by the compression ring angle, bar, or girder, as computed from the ratio of the cross-sectional area of the compression ring to the total area of the compression zone

R_c

= horizontal radius, in., of the cylindrical sidewall of the tank at its juncture with the roof or bottom

k

= a constant whose value depends on the magnitude of the angle θ , subtended at the central axis of the tank by the space between adjacent brackets or other supports, which value shall be determined from the tabulation in Table ND-3933.5(h)-1, in which n is the number of brackets or other supports evenly spaced around the circumference of the tank

⁵³ Note that the value required for I_1 as calculated from Eq. (28) is not applicated for materials other than steel.

**TABLE ND-3933.5(h)-1
SOME VALUES FOR k BASED ON n, θ**

n	30	24	20	18	15	12
θ , deg	12	15	18	20	24	30

θ , deg	36	40	45	60	72	90
k	20.0	16.0	12.5	6.7	4.4	2.6

GENERAL NOTE: In no case shall θ be larger than 90 deg.

TABLE ND-3933.5(h)-1 SOME VALUES FOR k BASED ON n, θ

ND-3934 Nozzle Piping Transitions

The stress limits of Table ND-3921.8-1 shall apply to all portions of nozzles which lie within the limits of reinforcement given in ND-3334, except as provided in ND-3935. Stresses in the extension of any nozzle beyond the limits of reinforcement shall be subject to the stress limits of ND-3600.

ND-3935 Consideration of Standard Reinforcement

(a) Where a nozzle-to-shell junction is reinforced in accordance with the rules of ND-3334, the stresses in this region due to internal pressure may be considered to satisfy the limits of Table ND-3921.8-1. Under these conditions, no analysis is required to demonstrate compliance for pressure induced stresses in the nozzle region.

(b) Where external piping loads are to be designed for, membrane plus bending stresses due to these loads shall be calculated in the nozzle, and membrane stresses shall be calculated in the local nozzle-to-shell region. These stresses, in conjunction with pressure induced stresses, shall meet the limits of Table ND-3921.8-1 for $(\sigma_m \text{ or } \sigma_L) + \sigma_b$. In this case, the pressure induced stresses in the $(\sigma_m \text{ or } \sigma_L) + \sigma_b$ category may be assumed to be no greater than the limit specified for σ_m in Table ND-3921.8-1, for a given condition.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 ND-4000

ARTICLE ND-4000 FABRICATION AND INSTALLATION

Page 205

ND-4100 GENERAL REQUIREMENTS

ND-4110 INTRODUCTION

(a) Components, parts, and appurtenances shall be fabricated and installed in accordance with the rules of this Article and shall be manufactured from materials which meet the requirements of ND-2000.

(b) Atmospheric and 0-15 psi (0-103 kPa) storage tanks shall be fabricated in accordance with the rules of this Article.

ND-4120 CERTIFICATION OF MATERIAL AND FABRICATION BY COMPONENT CERTIFICATE HOLDER

ND-4121 Means of Certification

The Certificate Holder for an item shall certify, by application of the appropriate Code Symbol and completion of the appropriate Data Report in accordance with NCA-8000, that the material used complies with the requirements of ND-2000 and that the fabrication or installation complies with the requirements of this Article.

ND-4121.1 Certification of Treatments, Tests, and Examinations.

If a Certificate Holder or Subcontractor performs treatments, tests, repairs, or examinations required by other Articles of this Subsection, the Certificate Holder shall certify that this requirement has been fulfilled (NCA-3862). Reports of all required treatments and of the results of all required tests, repairs, and examinations performed shall be available to the Inspector.

ND-4121.2 Repetition of Tensile or Impact Tests.

If during the fabrication or installation of the item the material is subjected to heat treatment that has not been covered by treatment of the test coupons (ND-2200) and that may reduce either tensile or impact properties below the required values, the tensile and impact tests shall be repeated by the Certificate Holder on test specimens taken from test coupons which have been taken and treated in accordance with the requirements of ND-2000.

ND-4121.3 Repetition of Surface Examination After Machining.

During the fabrication or installation of an item if materials for pressure containing parts are machined, the Certificate Holder shall reexamine the surface of the material in accordance with ND-2500 when:

(a) the surface was required to be examined by the magnetic particle or liquid penetrant method in accordance with ND-2500; and

(b) the amount of material removed from the surface exceeds the lesser of $\frac{1}{8}$ in. (3.2 mm) or 10% of the minimum required thickness of the part.

ND-4122 Material Identification

(a) Material for pressure retaining parts shall carry identification markings which will remain distinguishable until the component is assembled or installed. If the original identification markings are cut off or the material is divided, the same marks shall either be transferred to the parts cut or a coded marking shall be used to assure identification of each piece of material during subsequent fabrication or installation. In either case, an as-built sketch or a tabulation of materials shall be made identifying each piece of material with the Certified Material Test Report, where applicable, and the coded marking. For studs, bolts, nuts, and heat exchanger tubes it is permissible to identify the Certified Material Test Reports for material in each component in lieu of identifying each piece of material with the Certified Material Test Report and the coded marking. Material supplied with a Certificate of Compliance, and welding and brazing material, shall be identified and controlled so that they can be traced to each component or installation of a piping system, or else a control

Page 212

procedure shall be employed which ensures that the specified materials are used.

(b) Material from which the identification marking is lost shall be treated as nonconforming material until appropriate tests or other verifications are made and documented to assure material identification. Testing is required unless positive identification can be made by other documented evidence. The material may then be remarked upon establishing positive

identification.

ND-4122.1 Marking Material.

Material shall be marked in accordance with ND-2150.

ND-4123 Examinations

Visual examination activities that are not referenced for examination by other specific Code paragraphs, and are performed solely to verify compliance with requirements of ND-4000, may be performed by the persons who perform or supervise the work. These visual examinations are not required to be performed by personnel and procedures qualified to ND-5100 and ND-5500, respectively, unless so specified.

ND-4125 Testing of Welding and Brazing Material

All welding and brazing material shall meet the requirements of ND-2400.

ND-4130 REPAIR OF MATERIAL

Material originally accepted on delivery in which defects exceeding the limits of ND-2500 are known or discovered during the process of fabrication or installation is unacceptable. The material may be used provided the condition is corrected in accordance with the requirements of ND-2500 for the applicable product form, except that:

- (a) the limitation on the depth of the weld repair does not apply; and
- (b) the time of examination of the weld repairs to weld edge preparations shall be in accordance with ND-5120;
- (c) radiographic examination is not required for weld repairs to seal membrane material when the material thickness is $\frac{1}{4}$ in. (6 mm) or less;
- (d) radiographic examination is not required for welded repairs in material used in components, provided that the welded joints in these materials are not required to be radiographed, the extent of the welded repair does not exceed 10 sq in. (6452 mm²) of the surface area, and the magnetic particle or liquid penetrant examination of the repair is made as required by ND-2539.4.

ND-4200 FORMING, FITTING, AND ALIGNING

ND-4210 CUTTING, FORMING, AND BENDING

ND-4211 Cutting

Materials may be cut to shape and size by mechanical means such as machining, shearing, chipping, or grinding, or by thermal cutting.

ND-4211.1 Preheating Before Thermal Cutting.

When thermal cutting is performed to prepare weld joints or edges, to remove attachments or defective material, or for any other purpose, consideration shall be given to preheating the material, using preheat schedules such as suggested in Appendix D.

ND-4212 Forming and Bending Processes

Any process may be used to hot or cold form or bend pressure retaining material, including weld metal, provided the required dimensions are attained (see ND-4214 and ND-4220), and provided the impact properties of the materials, when required, are not reduced below the minimum specified values or they are effectively restored by heat treatment following the forming operation. *Hot forming* is defined as forming with the material temperature higher than 100°F (56°C) below the lower transformation temperature of the material. When required, the process shall be qualified for impact properties as outlined in ND-4213. When required, the process shall be qualified to meet thickness requirements as outlined in ND-4223.1.

ND-4213 Qualification of Forming Processes for Impact Property Requirements

When impact testing is required by the Design Specifications a procedure qualification test shall be conducted using specimens taken from material of the same specification, grade or class, heat treatment, and with similar impact properties as required for the material in the component. These specimens shall be subjected to the equivalent forming or bending process and heat treatment as the material in the component. Applicable tests shall be conducted to determine that the required impact properties of ND-2300 are met after straining.

Page 213

ND-4213.1 Exemptions.

Procedure qualification tests are not required for materials listed in (a) through (f) below:

- (a) hot formed material, such as forging, in which the hot forming is completed by the Material Organization prior to removal of the impact test specimens;
- (b) hot formed material represented by test coupons which has been subjected to heat treatment representing the hot forming procedure and the heat treatments to be applied to the parts;
- (c) material which does not require impacts in accordance with ND-2300;
- (d) material which has a final strain less than 0.5%;
- (e) material where the final strain is less than that of a previously qualified procedure for that material;
- (f) material from which the impact testing required by ND-2300 is performed on each heat and lot, as applicable, after forming.

[98]

ND-4213.2 Procedure Qualification Test.

The procedure qualification test shall be performed in the manner stipulated in (a) through (f) below.

- (a) The tests shall be performed on three different heats of material both before straining and after straining and heat treatment to establish the effects of the forming and subsequent heat treatment operations.
- (b) Specimens shall be taken in accordance with the requirements of ND-2000 and shall be taken from the tension side of the strained material.
- (c) The percent strain shall be established by the following equations.

For cylinders:

$$\% \text{ strain} = \frac{50t}{R_f} \left(1 - \frac{R_f}{R_o} \right)$$

For spherical or dished surfaces:

$$\% \text{ strain} = \frac{75t}{R_f} \left(1 - \frac{R_f}{R_o} \right)$$

For pipe:

$$\% \text{ strain} = \frac{100r}{R}$$

where

t	= nominal thickness, in.
R_f	= final radius to center line of shell, in.
R_n	= original radius (equal to infinity for a flat part), in.
R	= nominal bending radius to the center line of the pipe, in.
r	= nominal radius of the pipe, in.

(d) The procedure qualification shall simulate the maximum percent surface strain, employing a bending process similar to that used in the fabrication of the material or by direct tension on the specimen.

(e) Sufficient Charpy V-notch test specimens shall be taken from each of the three heats of material to establish a transition curve showing both the upper and lower shelves. On each of the three heats, tests consisting of three impact specimens shall be conducted at a minimum of five different temperatures distributed throughout the transition region. The upper and lower shelves may be established by the use of one test specimen for each shelf. Depending on the product form, it may be necessary to plot the transition curves using both the lateral expansion and energy level data (ND-2300). In addition, drop weight tests shall be made when required by ND-2300.

(f) Using the results of the impact test data from each of three heats, taken both before and after straining, determine either of (1) or (2) below:

(1) the maximum change in NDT temperature along with:

(a) the maximum change of lateral expansion and energy at the temperature under consideration, or

(b) the maximum change in temperature at the lateral expansion and energy levels under consideration; or

(2) where lateral expansion is the acceptance criteria (ND-2300), either the maximum change in temperature or the maximum change in lateral expansion.

[98]

ND-4213.3

ND-4213.3 Acceptance Criteria for Formed Material.

To be acceptable, the formed material used in the component shall have impact properties before forming sufficient to compensate for the maximum loss of impact properties due to the qualified forming procedure used.

ND-4213.4 Requalification.

A new procedure qualification test is required when any of the following changes in (a), (b), or (c) below are made:

(a) the actual postweld heat treatment time at temperature is greater than previously qualified considering ND-2211; if the material is not postweld heat treated, the procedure must be qualified without postweld heat treatment;

(b) the maximum calculated strain of the material exceeds the previously qualified strain by more than 0.5%;

(c) where preheat over 250°F (121°C) is used in the forming or bending operation but not followed by a subsequent postweld heat treatment.

Page 214

**FIG. ND-4221.1-1 MAXIMUM DIFFERENCE
IN CROSS-SECTIONAL DIAMETERS**

FIG. ND-4221.1-1 MAXIMUM DIFFERENCE IN CROSS-SECTIONAL DIAMETERS

ND-4214 Minimum Thickness of Fabricated Material

If any fabrication operation reduces the thickness below the minimum required to satisfy the rules of ND-2124 and ND-3000, the material may be repaired in accordance with ND-4130.

ND-4220 FORMING TOLERANCES

ND-4221 Tolerance for Vessel Shells

Cylindrical, conical, or spherical shells of a completed vessel except formed heads covered by ND-4222 shall meet the requirements of the following subparagraphs at all cross sections.

ND-4221.1 Maximum Difference in Cross-Sectional Diameters.

The difference in inches between the maximum and minimum diameters at any cross section shall not exceed the smaller of $(D + 50)/200$ and $D/100$, where D is the nominal inside diameter in inches at the cross section under consideration. The diameters may be measured on the inside or outside of the vessel. If measured on the outside, the diameters shall be corrected for the plate thickness at the cross section under consideration (Fig. ND-4221.1-1). When the cross section passes through an opening, the permissible difference in inside diameters given herein may be increased by 2% of the inside diameter of the opening. For vessels with longitudinal lap joints, the permissible difference in inside diameters may be increased by the nominal plate thickness.

ND-4221.2 Maximum Deviation From True Theoretical Form for External Pressure.

Vessels designed for external pressure shall meet the following tolerances.

(a) The maximum plus or minus deviation from the true circular form of cylinders or the theoretical form of other shapes, measured radially on the outside or inside of the component, shall not exceed the maximum permissible deviation obtained from Fig. ND-4221.2(a)-1. Measurements shall be made from a segmental circular template having the design inside or outside radius depending on where the measurements are taken and a chord length equal to twice the arc length obtained from Fig. ND-4221.2(a)-2. For Fig. ND-4221.2(a)-1, the maximum permissible deviation e need not be less than $0.3t$. For Fig. ND-4221.2(a)-2, the arc length need not be greater than $0.3D_o$. Measurements shall not be taken on welds or other raised parts.

(b) The value of t in inches at any cross section is the nominal plate thickness less corrosion allowance for sections of constant thickness and the nominal thickness of the thinnest plate less corrosion allowance for sections having plates of more than one thickness. For vessels with longitudinal lap joints, t is the nominal plate thickness and the permissible deviation is $(t + e)$.

(c) The value of L in Figs. ND-4221.2(a)-1 and ND-4221.2(a)-2 is determined by (1) through (3) below.

(1) For cylinders, L is as given in ND-3133.2.

(2) For cones, L is the axial length of the conical section if no stiffener rings are used or, if stiffener rings are used, the axial length from the head bend line at the large end of the cone to the first stiffener ring, with D_o taken as the outside diameter in inches of the cylinder at the large end of the cone.

(3) For spheres, L is one-half of the outside diameter D_o in.

(d) The dimensions of a completed vessel may be brought within the requirements by any process which will not impair the strength of the material.

(e) Sharp bends and flat spots shall not be permitted unless provision is made for them in the design.

ND-4221.3 Deviations From Tolerances.

Deviations from the tolerance requirements stipulated in ND-4221.1 and ND-4221.2 are permitted, provided the drawings are modified and reconciled with the design calculations.

ND-4221.4 Tolerance Deviations for Vessel Parts Fabricated From Pipe.

Vessel parts subjected to either internal or external pressure and fabricated from pipe, meeting all other requirements of this Subsection, may have variations of diameter and deviations from circularity permitted by the specification for such pipe.

ND-4221.5 Localized Thin Areas.

Localized thin areas are permitted if the adjacent areas surrounding each has sufficient thickness to provide the necessary reinforcement according to the rules for reinforcement in ND-3330.

FIG. ND-4221.2(a)-1 MAXIMUM PERMISSIBLE DEVIATION e FROM A TRUE CIRCULAR FORM

FIG. ND-4221.2(a)-1 MAXIMUM PERMISSIBLE DEVIATION e FROM A TRUE CIRCULAR FORM

ND-4222 Tolerances for Formed Vessel Heads

The tolerances for formed vessel heads shall be as set forth in the following subparagraphs.

ND-4222.1 Maximum Difference in Cross-Sectional Diameters.

The skirt or cylindrical end of a formed head shall be circular to the extent that the difference in inches between the maximum and minimum diameters does not exceed the lesser of $(D + 50)/200$ and $(D + 12)/100$, where D is the nominal inside diameter in inches and shall match the cylindrical edge of the adjoining part within the alignment tolerance specified in ND-4232.

ND-4222.2 Deviation From Specified Shape

(a) The inner surface of a torispherical or ellipsoidal head shall not deviate outside the specified shape by more than $1\frac{1}{4}\%$ of D , nor inside the specified shape by more than $\frac{5}{8}\%$ of D , where D is the nominal inside diameter of the vessel. Such deviations shall be measured perpendicular to the specified shape and shall not be abrupt. The knuckle radius shall not be less than specified. For 2:1 ellipsoidal heads, the knuckle radius may be considered to be 17% of the diameter of

the vessel.

(b) Hemispherical heads and any spherical portion of a formed head shall meet the local tolerances for spheres as given in ND-4221.2, using L as the outside spherical radius in inches and D_o as two times L .

(c) Deviation measurements shall be taken on the surface of the base material and not on welds.

ND-4223 Tolerances for Formed or Bent Piping

The tolerances for formed or bent piping shall be as set forth in the following subparagraphs.

Page 216

FIG. ND-4221.2(a)-2 MAXIMUM ARC LENGTH FOR DETERMINING PLUS OR MINUS DEVIATION

FIG. ND-4221.2(a)-2 MAXIMUM ARC LENGTH FOR DETERMINING PLUS OR MINUS DEVIATION

[98]

ND-4223.1 Minimum Wall Thickness

(a) In order to assure that the wall thickness requirements of the design calculations are met, the actual thickness shall be measured, or the process shall be qualified by demonstrating that it will maintain the required wall thickness.

(b) As an alternative to (a) above, the requirements of Table ND-3642.1(c)-1 shall be followed.

[98]

ND-4223.2 Ovality Tolerance.

Unless otherwise justified by the design calculations, the ovality of piping after bending shall not exceed 8% as determined by:

$$100 \times (D_{\max} - D_{\min})/D_o$$

where

D_o	= the nominal pipe outside diameter, in.
$D_{\min}$	= the minimum outside diameter after bending or forming, in.
$D_{\max}$	= the maximum outside diameter after bending or forming, in.

ND-4224 Tolerances for Storage Tanks

The horizontal circular cross section of storage tanks shall be sufficiently true to round so that the difference between the maximum and minimum diameters measured inside or outside at any section in a cylindrical wall shall not exceed 1% of the average diameter or 12 in. (305 mm), whichever is less, measured 6 ft (1.8 m) or one plate width from the top or bottom juncture, respectively, if these junctures are of a type which offers serious restraint when the tank is filled or under the specified maximum vapor pressure. At

Page 217

any section in a sidewall having double curvature, this difference in diameter shall not exceed $\frac{1}{2}\%$ of the average diameter or 6 in., whichever is less.

ND-4224.1 Maximum Difference in Cross-Sectional Diameters for Tanks of Double Curvature.

For tanks of double curvature, the meridian curvature of the plate surface shall not deviate from the design shape by more than $\frac{1}{2}\%$ of the radius, measured radially, and shall not show abrupt changes. Plate surfaces shall merge smoothly into the adjoining surfaces in all directions. Local inward deviations, such as flat spots, shall be limited by ND-4224.2.

ND-4224.2 Local Inward Deviations.

Local inward deviations, such as flat spots, if present on wall or bottom surfaces having double curvature, shall not be greater than the plate thickness and shall not have a diameter d greater than $\sqrt{8Rt}$, where R is the radius of the tank and t is the thickness of the plate involved. R shall be taken as R_1 , with d being the chord in a meridional direction, and as R_2 , with d being the chord in a latitudinal direction.

ND-4224.3 Tolerance Measurements.

The tolerance measurements are given for a tank while empty and shall be taken with a steel tape, making corrections for temperature, sag, and wind.

ND-4230 FITTING AND ALIGNING

ND-4231 Fitting and Aligning Methods

Parts that are to be joined by welding may be fitted, aligned, and retained in position during the welding operation by the use of bars, jacks, clamps, tack welds, or temporary attachments.

ND-4231.1 Tack Welds.

Tack welds used to secure alignment either shall be removed completely when they have served their purpose, or their stopping and starting ends shall be properly prepared by grinding or other suitable means so that they may be satisfactorily incorporated into the final weld. Tack welds shall be made by qualified welders using qualified welding procedures. When tack welds are to become part of the finished weld, they shall be visually examined and defective tack

procedures. When tack welds are to become part of the finished weld, they shall be visually examined and defective tack welds removed.

**TABLE ND-4232(a)-1
MAXIMUM ALLOWABLE OFFSET IN
FINAL WELDED JOINTS**

Section Thickness, in.	Direction of Joints	
	Longitudinal	Circumferential
Up to $\frac{1}{2}$, incl.	$\frac{1}{4}t$	$\frac{1}{4}t$
Over $\frac{1}{2}$ to $\frac{3}{4}$, incl	$\frac{1}{8}$ in.	$\frac{1}{4}t$
Over $\frac{3}{4}$ to $1\frac{1}{2}$, inc.	$\frac{1}{8}$ in.	$\frac{3}{16}$ in.
Over $1\frac{1}{2}$ to 2, inc.	$\frac{1}{8}$ in.	$\frac{1}{8}t$
Over 2	Lesser of $\frac{1}{16}t$ or $\frac{3}{8}$ in.	Lesser of $\frac{1}{8}t$ or $\frac{3}{4}$ in.

TABLE ND-4232(a)-1 MAXIMUM ALLOWABLE OFFSET IN FINAL WELDED JOINTS

ND-4232 Alignment Requirements When Components Are Welded From Two Sides

(a) Alignment of sections which are welded from two sides shall be such that the maximum offset of the finished weld will not be greater than the applicable amount listed in Table ND-4232(a)-1, where t is the nominal thickness of the thinner section at the joint.

(b) Joints in spherical vessels and joints within heads and joints between cylindrical shells and hemispherical heads shall meet the requirements in Table ND-4232(a)-1 for longitudinal joints.

ND-4232.1 Fairing of Offsets.

Any offset within the allowable tolerance provided above shall be faired to at least a 3:1 taper over the width of the finished weld or, if necessary, by adding additional weld metal beyond what would otherwise be the edge of the weld.

ND-4233 Alignment Requirements When Inside Surfaces Are Inaccessible

(a) When the inside surfaces of items are inaccessible for welding or fairing in accordance with ND-4232, alignment of sections shall meet the requirements of (1) and (2) below.

(1)(a) For circumferential joints the inside diameters shall match each other within $\frac{1}{16}$ in (1.6 mm). When the items are aligned concentrically, a uniform mismatch of $\frac{1}{32}$ in. (0.8 mm) all around the joint can result as shown in Fig. ND-4233-1 sketch (a). However, other variables not associated with the diameter of the item often result in alignments

that are offset rather than concentric. In these cases, the maximum misalignment at any one point around the joint shall not exceed $\frac{3}{32}$ in. (2.4 mm) as shown in Fig. ND-4233-1 sketch (b). Should tolerances on diameter, wall thickness, out-of-roundness, etc., result in inside diameter variations

Page 218

Page 219

which do not meet these limits, the inside diameters shall be counterbored, sized, or ground to produce a bore within these limits, provided the requirements of ND-4250 are met.

GENERAL NOTE:

The weld end transitions are typical and are not intended as requirements. Refer to ND-4250 for weld end transition requirements.

FIG. ND-4233-1 BUTT WELD ALIGNMENT AND MISMATCH TOLERANCES FOR UNEQUAL I.D. AND O.D. WHEN COMPONENTS ARE WELDED FROM ONE SIDE AND FAIRING IS NOT PERFORMED

FIG. ND-4233-1 BUTT WELD ALIGNMENT AND MISMATCH TOLERANCES FOR UNEQUAL I.D. AND O.D. WHEN COMPONENTS ARE WELDED FROM ONE SIDE AND FAIRING IS NOT PERFORMED

(b) Offset of outside surfaces shall be faired to at least a 3:1 taper over the width of the finished weld or, if necessary, by adding additional weld metal.

(2) For longitudinal joints the misalignment of inside surfaces shall not exceed $\frac{3}{32}$ in. (2.4 mm), and the offset of outside surfaces shall be faired to at least a 3:1 taper over the width of the finished weld or, if necessary, by adding additional weld metal.

(b) Single welded joints may meet the alignment requirements of (1) and (2) above in lieu of the requirements of ND-4232.

ND-4240 REQUIREMENTS FOR WELD JOINTS IN COMPONENTS¹

ND-4241 Category A Weld Joints in Vessels and Longitudinal Weld Joints in Other Components

All Category A weld joints in vessels and longitudinal weld joints in other components shall meet the requirements of (a), (b), and (c) below.

(a) When the design is based on a joint efficiency permitted by ND-3352.1(a) or ND-3352.1(b), all Category A welds in vessels and longitudinal joints in other components shall be Type 1 or Type 2 as described in ND-4245.

(b) When the design is based on a joint efficiency permitted by ND-3352.1(c), any joint Type as described in ND-4245 may be used, provided the limitations of the joint are followed.

(c) When the component is constructed of P-No. 11A, Group 1 material, Type 1 joints as described in ND-4245 shall be used.

ND-4242 Category B Weld Joints in Vessels and Circumferential Weld Joints in Other Components

Category B weld joints in vessels and circumferential weld joints in other components shall meet the requirements of (a) and (b) below, except that piping 2 in. NPS (DN 50) and smaller may be socket welded.

¹ See ND-4246 and ND-4247 for special weld joint requirements in storage tanks.

(a) When the design is based on a joint efficiency permitted by ND-3352.1(a) or ND-3352.1(b), or when P-No. 11A, Group 1 materials are joined, all Category B welds in pressure vessels and circumferential joints in other components shall be Type 1 or Type 2 as described in ND-4245.

(b) When the design is based on a joint efficiency permitted by ND-3352.2(c), any joint Type as described in ND-4245 may be used, provided the limitations of the joint are followed.

ND-4243 Category C Weld Joints in Vessels and Similar Joints in Other Components

Category C weld joints in vessels and similar weld joints in other components shall meet the requirements of (a), (b), and (c) below, except that socket welded flanges NPS 2 (DN 50) and less and slip-on flanges may be used.

(a) Category C and similar weld joints shall be Type 1 or Type 2 as described in ND-4245(a) when a butt weld detail is used and the provisions of ND-3352.1(a) or ND-3352.2(b) apply. These joints must be Type 1 or Type 2 butt welds when the joint is required to be radiographed.

(b) Typical Category C corner joints are shown in Fig. ND-4243-1 and Appendix XI.

(c) All category C joints in P-No. 11A, Group 1 material shall be full penetration welds extending through the entire section of the joint.

ND-4243.1 Flat Heads and Tubesheets With Hubs.

Hubs for butt welding to the adjacent shell, head, or other pressure part, as in Fig. ND-4243.1-1, shall not be machined from rolled plate. The component having the hub shall be forged in such a manner as to provide in the hub the full minimum tensile strength and elongation specified for the material, in a direction parallel to the axis of the vessel. Proof of this shall be furnished by a tension test specimen, subsize if necessary, taken in this direction and as close to the hub as is practical.² In no case shall the height of the hub be less than 1.5 times the thickness of the pressure part to which it is welded.

ND-4244 Category D Weld Joints in Vessels and Branch Connection Weld Joints in Other Components

² One test specimen may represent a group of forgings, provided they are of the same nominal dimensions, from the same heat of material, the same heat treatment lot, and forged in the same manner.

Category D weld joints in vessels and branch connection weld joints in other components shall be welded using one of the details of (a) through (g) below except

Page 220

that joints in P-No. 11A, Group 1 material shall be full penetration welds extending through the entire thickness of the component wall or nozzle wall as shown in Figs. ND-4244(a)-1, ND-4244(b)-1, and ND-4244(c)-1.

(a) Butt Welded Nozzles and Branch Piping Connections. Nozzles and branch piping connections shall be attached by full penetration butt welds through the wall of the component nozzle or branch as shown in Fig. ND-4244(a)-1. Backing strips, if used, may be left in place.

(b) Corner Welded Nozzles and Branch Piping Connections. Nozzles and branch piping connections shall be joined to the component by full penetration welds through the wall of the component, nozzle, or branch similar to those shown in Fig. ND-4244(b)-1. When complete joint penetration cannot be verified by visual examination or other means permitted, backing strips or equivalent shall be used with full penetration welds deposited from only one side. Backing strips, if used, may be left in place.

(c) Deposited Weld Metal of Opening for Nozzles and Branch Piping Connections. Nozzles and branch piping connections shall be joined to the component by full penetration weld to built-up weld deposits applied to the component, nozzle, or branch as shown in Fig. ND-4244(c)-1. Backing strips, if used, may be left in place. Fillet welds shall be used only to provide

a transition between the parts joined or to provide a seal. The fillet welds, when used, shall be finished by grinding to
provide a smooth surface having a transition radius at its intersection with either part being joined. Pages 221-221

FIG. ND-4243-1 ATTACHMENT OF PRESSURE PARTS TO PLATES TO FORM A CORNER JOINT (CONT'D)

(d) *Partial Penetration Welded Nozzle and Branch Piping Connections.* Partial penetration welds in components and branch piping connections shall meet the weld design requirements of ND-3352.4(d) and ND-3359. Nozzles shall be attached as shown in Fig. ND-4244(d)-1. Reinforcing plates of nozzles attached to the outside of a vessel shall be provided with at least one telltale hole, maximum size $\frac{1}{4}$ in. pipe tap, that may be tapped for a preliminary compressed air and soapsuds test for tightness of welds that seal off the inside of the vessel. These telltale holes may be left open or may be plugged when the vessel is in service. If the holes are plugged, the plugging material used shall not be capable of sustaining pressure between the reinforcing plate and the vessel wall.

³ Written and illustrated with internal threads, but also applicable to externally threaded and socket or butt welded fittings.

(e) *Attachment of Fittings With Internal Threads.*³ Internally threaded fittings shall be attached by a full penetration groove weld or, for NPS 3 (DN 80) and less, by two fillet or partial penetration welds, one on

each face of the vessel wall, or by a fillet groove weld from the outside only as shown in Fig. ND-4244(e)-1 sketch (c-3). Internally threaded fitting and bolting pads not exceeding NPS 3, as shown in Fig. ND-4244(e)-2, may be attached to components having a wall thickness not greater than $\frac{3}{8}$ in. (10 mm) by a fillet weld, deposited from the outside only. The design requirements of ND-3352.4(e) shall be met for all components.

GENERAL NOTE:

Not permissible if machined from rolled plate. The tension test specimen may be located, when possible, inside the forged hub, instead of outside, as shown.

FIG. ND-4243.1-1 TYPICAL FLAT HEADS, AND SUPPORTED AND UNSUPPORTED TUBESHEETS WITH HUBS

FIG. ND-4243.1-1 TYPICAL FLAT HEADS, AND SUPPORTED AND UNSUPPORTED TUBESHEETS WITH HUBS

(f) *Tubed Connections.* Nozzles or tubes recessed into thick-walled components or parts may be welded from only one side, provided the requirements of ND-3352.4(f) are met. Typical connections are shown in Fig. ND-4244(f)-1.

(g) *Nozzles With Integral Reinforcing.* Nozzles and other connections having integral reinforcing in the form of external necks or saddle type pads shall be attached by full penetration welds or by means of a

FIG. ND-4244(e)-1 SOME ACCEPTABLE TYPES OF WELDED NOZZLES

ND-4245 Description and Limitations of Joint Types

(a) For components the description of the joint types are as follows:

Type	Description
1	Butt joints as attained by double welded or by other means will obtain the same quality of deposit weld metal on the inside and outside surface to agree with the requirements of ND-4426. Welds using metal backing strips which remain in place are excluded.
2	Single welded butt joints with backing strips other than those included in Type 1
3	Single welded butt joints without the use of a backing strip
4	Double full fillet lap joints
5	Single full fillet lap joints with plug welds conforming to ND-3356.2
6	Single full fillet lap joints without plug welds

(b) The limitations for each Type of weld are as outlined below. Some typical configurations are shown in Fig. ND-4245-1.

Type	Limitations
1	The use of this joint Type is not limited.
2	The use of this joint Type is not limited, except for butt welds with one plate offset which can be used for circumferential joints only and are limited by the provisions of ND-3358.5 [Fig. ND-4245-1 sketch (k)].
3	This joint Type is limited to circumferential joints only, which are not over $\frac{5}{8}$ in. (16 mm) thick and not over 24 in. (610 mm) outside diameter.
4	This joint Type is limited to longitudinal joints not over $\frac{3}{8}$ in. (10 mm) thick and circumferential joints not over $\frac{5}{8}$ in. (16 mm) thick.
5	This joint Type is limited to circumferential joints for attachments of heads other than hemispherical not over 24 in. (610 mm) outside diameter to shells not over $\frac{1}{2}$ in. (13 mm) thick. This joint Type cannot be used for attaching hemispherical heads to shells.
6	This joint Type is limited to attachment of heads convex to pressure to shells not over $\frac{5}{8}$ in. required thickness, using fillet welds on the inside of the shell or for the attachment of heads having pressure on either side, to shells not over 24 in. inside diameter and not over $\frac{1}{4}$ in. required thickness with the fillet welds on the outside of the head flange only.

FIG. ND-4244(e)-2 SOME ACCEPTABLE TYPES OF SMALL FITTINGS

ND-4246 Atmospheric Storage Tank Special Joints

Requirements for special joints for atmospheric storage tanks are given below.

GENERAL NOTE: When used for other than square, round, or oval headers, round off corners.

FIG. ND-4244(f)-1 TUBE CONNECTIONS
For Definition of Symbols, See ND-3352.4(f)

FIG. ND-4244(f)-1 TUBE CONNECTIONS

ND-4246.1 Bottom Plates.

Bottoms shall be built to either one of the alternative methods of construction given in (a) and (b) below.

(a) Lap welded bottom plates shall be reasonably rectangular and square edged. Three plate laps in tank bottoms shall not be closer than 12 in. (305 mm) from each other and also from the tank shell. Bottom plates need be welded on the top side only, with a continuous full fillet weld on all seams [Fig. ND-4246.1(a)-1]. The plates under the bottom ring shell connection shall have the outer ends of the joints fitted and lap welded to form a smooth bearing for the shell plates, as shown in Fig. ND-4246.1(a)-1.

(b) Butt welded bottom plates shall have the parallel edges prepared for butt welding with either square or V-grooves. If square grooves are employed, the root opening shall be not less than $\frac{1}{4}$ in. (6 mm). The butt welds shall be made by applying a backing strip $\frac{1}{8}$ in. thick or heavier by tack welding to the underside of the plate [Fig. ND-4246.1(a)-1]. A metal spacer shall be used, if necessary, to maintain the root opening between the adjoining plate edges. The Certificate Holder may submit other methods of butt welding the bottom for the Owner's approval. Three plate joints in tank bottoms shall not be closer than 12 in. (305 mm) from each other and also from the tank shell.

ND-4246.2 Shell-to-Bottom Attachment.

The attachment between the bottom edges of the lowest course shell plate and the bottom plate shall be a continuous full wall thickness weld with a cover fillet on each side of shell plate [Fig. ND-4246.1(a)-1], or for tanks not exceeding 35 ft (10.6 mm) in diameter the bottom plates may be flanged and butt welded to the bottom shell course. The flanged tank bottom plates shall be butt welded and have a thickness equal to the thickness of the bottom shell course. The inside radius of the bend shall be not less than $1.75t$ nor more than $3t$.

ND-4246.3 Roof-to-Sidewall Attachment.

Roof plates shall be attached to the top angle of the tank with a continuous fillet weld on the top side only (Fig. ND-4246.3-1). Roof plates of supported cone roofs shall not be attached to the supporting members. For cone roofs the fillet weld shall be $\frac{3}{16}$ in. (4.8 mm) or smaller.

ND-4246.4 Roof Plates.

Roof plates shall be attached at least by a continuous full fillet lap joint on the top side (Fig. ND-4246.3-1). The top angle sections for self-supporting roofs shall be joined by full penetration butt welds.

ND-4246.5 Nozzle-to-Tank Joints.

Nozzles, manholes, and outlets shall be attached by full fillet welds as shown in Figs. ND-4246.5-1, ND-4246.5-2, ND-4246.5-3, and ND-4246.5-4.

[98]

ND-4246.6 Special Requirements.

Special weld requirements for storage tanks are given in (a) through (d) below.

(a) The minimum size of fillet welds shall be as follows: plates $\frac{3}{16}$ in. (4.8 mm) thick, full fillet welds; plates over $\frac{3}{16}$ in. (4.8 mm) thick, not less than one-third the thickness of the thinner plate at the joint, with a minimum of $\frac{3}{16}$ in. (4.8 mm).

(b) Lap welded joints, as tack welded, shall be lapped not less than five times the nominal thickness of the thinner plate joined; but in the case of double welded lap joints the lap need not exceed 2 in. (51 mm), and

Page 230

Page 231

FIG. ND-4245-1 ATTACHMENT WELDS

FIG. ND-4245-1 ATTACHMENT WELDS (CONT'D)

FIG. ND-4245-1 ATTACHMENT WELDS (CONT'D)

in the case of single welded lap joints the lap need not exceed 1 in. (25 mm).

FIG. ND-4246.1(a)-1 TYPICAL BOTTOM AND BOTTOM-TO-SHELL JOINTS

FIG. ND-4246.1(a)-1 TYPICAL BOTTOM AND BOTTOM-TO-SHELL JOINTS

(c) For plates over $\frac{1}{2}$ in. (13 mm) thick in the sidewalls, roof, or bottom of the tank, if the thickness of two adjacent plates which are to be butt welded together differs more than $\frac{1}{8}$ in. (3.2 mm), the thicker plate shall be trimmed to a smooth taper extending for a distance at least three times the offset between the abutting surfaces so that the adjoining edges will be approximately the same thickness (Fig. ND-3361.1-1). The length of the required taper may include the width of the weld.

(d) Top angle sections for self-supporting roofs shall be joined by full penetration butt welds.

[98]

ND-4246.7

weld joints, are the same as given in ND-4240 for Category A, B, and C weld joints for vessels.

FIG. ND-4246.3-1 TYPICAL ROOF AND ROOF-TO-SHELL JOINTS

FIG. ND-4246.3-1 TYPICAL ROOF AND ROOF-TO-SHELL JOINTS

ND-4247 0-15 psi (0-103 kPa) Storage Tank Special Joints

Requirements for special joints for 0-15 psi (0-103 kPa) storage tanks are given below.

Requirements for special joints for 0-15 psi (0-103 kPa) storage tanks are given below.

ND-4247.1 Bottoms.

All welds in flat bottoms supported directly on foundations shall be single full fillet lap joints as a minimum. For other bottoms, all welds shall be butt welds.

ND-4247.2 Bottom-to-Sidewall.

All welds shall meet the design requirements of ND-3933. Flat bottoms shall be attached to sidewalls by full penetration welds and fillet welds on each side as a minimum.

FIG. ND-4246.5-1 ROOF MANHOLES

FIG. ND-4246.5-1 ROOF MANHOLES

ND-4247.3

Roof-to-sidewall joints shall be in accordance with the design requirements of ND-3933. The joints shall have continuous full fillet welds as a minimum.

ND-4247.4 Roofs.

Roofs shall be in accordance with the design requirements of ND-3933 and shall meet the requirements of ND-4241.

ND-4247.5 Nozzles.

Nozzle welds shall meet the requirements of ND-4244.

[98]

ND-4247.6 Special Requirements.

Special weld requirements for storage tanks are given in (a) through (d) below.

(a) The minimum size of fillet welds shall be as follows: plates $\frac{3}{16}$ in. (4.8 mm) thick, full fillet welds; plates over $\frac{3}{16}$ in. (4.8 mm) thick, not less than one-third the thickness of the thinner plate at the joint, with a minimum of $\frac{3}{16}$ in. (4.8 mm)

(b) Lap welded joints, as tack welded, shall be lapped not less than five times the nominal thickness of the thinner plate joined; but in the case of double welded lap joints the lap need not exceed 2 in. (51 mm), and in the case of single welded lap joints the lap need not exceed 1 in. (25 mm).

(c) For plates over $\frac{1}{2}$ in. (13 mm) thick in the sidewalls, roof, or bottom of the tank, if the thickness

Page 236

GENERAL NOTES:

- (a) Slip-on welding and welding neck flanges shall conform to the requirements for 150 lb forged carbon steel raised face flanges as given in ANSI B16.5.
- (b) Plate ring flanges shall conform to all dimensional requirements for slip-on welding flanges, except that the extended hub on the back of the flange may be omitted.

FIG. ND-4246.5-2 FLANGED ROOF NOZZLES

FIG. ND-4246.5-2 FLANGED ROOF NOZZLES

of two adjacent plates which are to be butt welded together differs more than $\frac{1}{8}$ in. (3.2 mm), the thicker plate shall be trimmed to a smooth taper extending for a distance at least three times the offset between the abutting surfaces so that the adjoining edges will be approximately the same thickness (Fig. ND-3361.1-1). The length of the required taper may include the width of the weld.

FIG. ND-4246.5-3 SCREWED OR SOCKET WELD ROOF NOZZLES

FIG. ND-4246.5-3 SCREWED OR SOCKET WELD ROOF NOZZLES

(d) The size of any weld along either edge of a compression ring shall not be less than the thickness of the thinner of the two parts joined or $\frac{1}{4}$ in. (6 mm), whichever is less, nor shall the size of the corner welds between the shell and a girder bar, such as shown in sketches (d) and (e) in Fig. ND-3933.5(d)-1, or between the horizontal and vertical members of a compression ring assembly, such as shown in sketches (f) and (i), be less than the applicable value specified in Table ND-4247.6(d)-1.

[98]

ND-4247.7 Other Weld Joints.

The fabrication requirements for weld joints not specifically covered by ND-4247, such as sidewall weld joints and nozzle-to-flange weld joints, are the same as given in ND-4240 for Category A, B, and C weld joints for vessels.

ND-4250 WELDING END TRANSITIONS - MAXIMUM ENVELOPE

The welding ends of items shall provide a gradual change in thickness from the item to the adjoining

FIG. ND-4246.5-4 WELDED BOTTOM OUTLET ELBOW

FIG. ND-4246.5-4 WELDED BOTTOM OUTLET ELBOW

items. Any welding end transition which lies entirely within the envelope shown in Fig. ND-4250-1 is acceptable, provided that:

**TABLE ND-4247.6(d)-1
MINIMUM SIZE FOR FILLET WELDS**

Thickness of the Thicker of the Two Parts Joined, in.	Minimum Size of Fillet Weld, in.
Not over $\frac{1}{4}$	$\frac{3}{16}$
Over $\frac{1}{4}$ through $\frac{3}{4}$	$\frac{1}{4}$
Over $\frac{3}{4}$ through $1\frac{1}{4}$	$\frac{5}{16}$
Over $1\frac{1}{4}$	$\frac{3}{8}$

TABLE ND-4247.6(d)-1 MINIMUM SIZE FOR FILLET WELDS

- (a) the wall thickness in the transition region is not less than the minimum wall thickness of the adjoining item; and
- (b) sharp reentrant angles and abrupt changes in slope in the transition region are avoided. When the included angle between any two adjoining surfaces of a taper transition is less than 150 deg, the intersection or corner (except for the weld reinforcement) shall be provided with a radius of at least $0.05t_{\min}$.

ND-4300 WELDING QUALIFICATIONS

ND-4310 GENERAL REQUIREMENTS

ND-4311 Types of Processes Permitted

Only those welding processes which are capable of producing welds in accordance with the welding procedure qualification requirements of Section IX and this Subsection may be used for welding pressure retaining material or attachments thereto. Any process used shall be such that the records required by ND-4320 can be prepared, except that records for stud welds shall be traceable to the welders and welding operators and not necessarily to each specific weld.

ND-4311.1 Stud Welding Restrictions.

Stud welding is acceptable only for nonstructural and temporary attachments (ND-4435). Studs shall be limited to 1 in. maximum diameter for round studs and an equivalent cross-sectional area for studs of other shapes when welding in the flat position and $\frac{3}{4}$ in. (19 mm) diameter for all other welding positions. Postweld heat treatment shall comply with ND-4600, except that time at temperature need not exceed $\frac{1}{2}$ hr regardless of base material thickness. Welding procedure and performance qualification shall comply with the requirements of Section IX.

GENERAL NOTES:

- (a) Weld bevel is shown for illustration only
- (b) The weld reinforcement permitted by ND-4426 may lie outside the maximum envelope.

NOTES:

- (1) The value of $t_{min.}$ is whichever of the following is applicable:
 - (a) the minimum ordered wall thickness of the pipe
 - (b) 0.875 times the nominal wall thickness of pipe ordered to a pipe schedule wall thickness which has an under tolerance of 12.5%
 - (c) the minimum ordered wall thickness of the cylindrical welding end of a component or fitting (or the thinner of the two) when the joint is between two components
- (2) The maximum thickness at the end of the component is:
 - (a) the greater of $(t_{min.} + 0.15 \text{ in.})$ or $1.15t_{min.}$, when ordered on a minimum wall basis
 - (b) the greater of $(t_{min.} + 0.15 \text{ in.})$ or $1.10t_{nom.}$, when ordered on a nominal wall basis.

FIG. ND-4250-1 WELDING END TRANSITIONS MAXIMUM ENVELOPE

FIG. ND-4250-1 WELDING END TRANSITIONS MAXIMUM ENVELOPE

ND-4311.2 Capacitor Discharge Welding.

Capacitor discharge welding may be used for welding temporary attachments and permanent nonstructural attachments provided:

- (a) temporary attachments are removed in accordance with the provisions of ND-4435(b);
- (b) the energy output for permanent nonstructural attachments such as strain gages and thermocouples is limited to 125 W-sec and the minimum thickness of the material to which the attachment is made is greater than 0.09 in. (2.3 mm); and
- (c) a Welding Procedure Specification is prepared describing the capacitor discharge equipment, the combination of materials to be joined, and the technique of application; qualification of the welding procedure is not required.

ND-4311.4 Inertia and Continuous Drive Friction Welding

- (a) Inertia and continuous drive friction welding shall not be used for the fabrication of piping.
- (b) The weld between the two members shall be a full penetration weld.

ND-4312 Production Test Plates

If a vessel of welded unalloyed titanium construction incorporates weld joints of Categories A or B, a production test plate of the same specification, grade, and thickness shall be made of sufficient size to provide at least one face and one root bend specimen. Where longitudinal joints are involved, the test plate shall be attached to one end of the longitudinal joint and welded continuously with the joint. Where circumferential joints only are involved, the test plate need not be attached but shall be welded along with the joint. One test plate is required for each vessel by each welder or welding operator working on the vessel, provided not over 100 ft (30.5 m) of Category A or B weld joints are involved. An additional test plate, meeting the same requirement as outlined above, shall be made for each additional 100 ft (30.5 m) of Category A or B weld joints involved. The bend specimens shall be tested in accordance with Section IX. Failure of either bend specimen constitutes rejection of the weld.

ND-4313 Unalloyed Titanium

Unalloyed titanium shall not be welded to other material.

ND-4320 WELDING QUALIFICATIONS, RECORDS, AND IDENTIFYING STAMPS

ND-4321 Required Qualifications

- (a) Each Certificate Holder is responsible for the welding done by his organization and shall establish the procedure and conduct the tests required by this Article and by Section IX in order to qualify both the welding procedures and the performance of welders and welding operators who apply these procedures.
- (b) Procedures, welders, and welding operators used to join permanent or temporary attachments to pressure parts and to make permanent or temporary tack welds used in such welding shall also meet the qualification requirements of this Article.
- (c) When making procedure test plates for butt welds, consideration shall be given to the effect of angular, lateral, and end restraint on the weldment. This applies particularly to material and weld metal of 80.0 ksi (552 MPa) tensile strength or higher and heavy sections of both low and high tensile strength material. The addition of restraint during welding may result in cracking difficulties that otherwise might not occur.
- (d) NCA-3131 provides specific additional requirements when welding services are subcontracted to or through organizations not holding an appropriate Certificate of Accreditation.

ND-4322 Maintenance and Certification of Records

The Certificate Holder shall maintain a record of his qualified welding procedures and of the welders and welding operators qualified by him, showing the date and results of tests and the identification mark assigned to each welder. These records shall be reviewed, verified, and signed by any authorized individual assigned by the Certificate Holder, and they shall be accessible to the Owner and to the Inspector.

ND-4322.1 Identification of Joints by Welder or Welding Operator

(a) Each welder or welding operator shall apply the identification mark assigned to him by the Certificate Holder on or adjacent to all permanent welded joints or series of joints on which he welds. The marking shall be at intervals of 3 ft (0.9 m) or less and shall be done with either blunt nose continuous or blunt nose interrupted dot die stamps. As an alternative, the Certificate Holder shall keep a record of permanent welded joints in each item and of the welders and welding operators used in making each of the joints.

Page 240

(b) When a multiple number of permanent structural attachment welds, nonstructural welds, fillet welds, socket welds, welds of specially designed seals, weld metal cladding, hard surfacing and tube-to-tubesheet welds, are made on an item, the Certificate Holder need not identify the welder or welding operator who welded each individual joint, provided:

(1) the Certificate Holder maintains a system that will identify the welders or welding operators who made such welds on each item so that the Inspector can verify that the welders or welding operators were all properly qualified;

(2) the welds in each category are all of the same type and configuration and are welded with the same Welding Procedure Specification.

(c) The identification of welder or welding operator is not required for tack welds.

ND-4323 Welding Prior to Qualification

No welding shall be undertaken until after the welding procedures which are to be used have been qualified. Only welders and welding operators who are qualified in accordance with ND-4320 and Section IX shall be used.

ND-4324 Transferring Qualifications

The welding procedure qualifications and performance qualification tests for welders and welding operators conducted by one Certificate Holder shall not qualify welding procedures, and shall not qualify welders or welding operators to weld for any other Certificate Holder, except as provided in Section IX, QW-201 and QW-300.2.

ND-4330 GENERAL REQUIREMENTS FOR WELDING PROCEDURE QUALIFICATION TESTS

ND-4331 Conformance to Section IX Requirements

All welding procedure qualification tests shall be in accordance with the requirements of Section IX as supplemented or modified by the requirements of this Article.

ND-4333 Heat Treatment of Qualification Welds for Ferritic Material

Postweld heat treatment of procedure qualification welds shall conform to the applicable requirements of ND-4600 and Section IX. The postweld heat treatment time at temperature shall be at least 80% of the maximum time to be applied to the component weld material. The postweld heat treatment total time may be applied in one heating cycle.

ND-4334 Preparation of Test Coupons and Specimens

(a) Removal of test coupons from the test weld and the dimensions of specimens made from them shall conform to the requirements of Section IX, except that the removal of impact test coupons and the dimensions of impact test specimens shall be in accordance with (b) below.

(b) Weld deposit of each process in a multiple process weld shall, where possible, be included in the impact test

specimens. When each process cannot be included in the full-size impact test specimen at the $\frac{1}{4}t$ location required by this Section, additional full-size specimens shall be obtained from locations in the test weld that will ensure that at least a portion of each process has been included in full-size test specimens. As an alternative, additional test welds can be made with each process so that full-size specimens can be tested for each process.

ND-4334.1 Coupons Representing the Weld Deposits.

Impact test specimens and testing methods shall conform to ND-2321. The impact specimen shall be located so that the longitudinal axis of the specimen is at least $\frac{1}{4}t$ and, where the thickness of the test assembly permits, not less than $\frac{3}{8}$ in. (10 mm) from the weld surface of the test assembly. In addition, when the postweld heat treatment temperature exceeds the maximum temperature specified in ND-4620, and the test assembly is cooled at an accelerated rate, the longitudinal axis of the specimen shall be a minimum of t from the edge of the test assembly. The specimen shall be transverse to the longitudinal axis of the weld with the area of the notch located in the weld. The length of the notch of the Charpy V-notch specimen shall be normal to the surface of the weld.

ND-4334.2 Coupons Representing the Heat Affected Zone.

Where impact tests of the heat affected zone are required by ND-4335.2, specimens shall be taken from the welding procedure qualification test assemblies in accordance with (a) through (c) below.

(a) If the qualification test material is in the form of a plate or a forging, the axis of the weld shall be oriented either parallel to or perpendicular to the principal direction of rolling or forging.

Page 241

(b) The heat affected zone impact test specimens and testing methods shall conform to the requirements of ND-2321. The specimens shall be removed from a location as near as practical to a depth midway between the surface and center thickness. The coupons for heat affected zone impact specimens shall be taken transverse to the axis of the weld and etched to define the heat affected zone. The notch of the Charpy V-notch specimen shall be cut approximately normal to the material surface in such a manner as to include as much heat affected zone as possible in the resulting fracture. Where the material thickness permits, the axis of a specimen may be inclined to allow the root of the notch to align parallel to the fusion line. When a grain refining heat treatment is not performed on welds made by the electroslag or electrogas welding process, the notch for the impact specimens shall be located in the grain coarsened region.

(c) For the comparison of heat affected zone values with base material values [ND-4335.2(b)], Charpy V-notch specimens shall be removed from the unaffected base material at approximately the same distance from the base material surface as the heat affected zone specimens. The axis of the unaffected base material specimens shall be parallel to the axis of the heat affected zone specimens, and the axis of the notch shall be normal to the surface of the base material.

ND-4335 Impact Test Requirements

When materials are required to be impact tested per ND-2300, impact tests of the weld metal and heat affected zone shall be performed in accordance with the following subparagraphs. Exemption from impact testing under ND-2311(a)(8) does not apply to weld metal unless the specific weld metal used is included in Table ND-2311(a)-1. Exemption from impact testing of the heat affected zone of those base materials exempted by ND-2311(a)(8) is not permitted. The weld procedure qualification impact test specimens shall be prepared and tested in accordance with the applicable requirements of ND-2330 and ND-4334. Retests in accordance with the provisions of ND-2350 are permitted.

ND-4335.1 Impact Tests of Weld Metal

(a) Impact tests of the weld metal shall be required for welding procedure qualification tests for production weld joints exceeding $\frac{5}{8}$ in. (16 mm) in thickness when the weld will be made on the surface or will penetrate the base material that requires impact testing in accordance with ND-2310. In addition, such testing of the weld metal is required for the welding procedure qualification tests for any weld repair to base material that requires impact testing in accordance with ND-2310, regardless of the depth of the repair. Exemption from impact testing under ND-2311(a)(8) does not apply to weld metal of welding procedure qualification tests for either production weld joints or base material repairs unless the specific weld metal used is included in Table ND-2311-1. Weld metal exemptions are being developed.

(b)

same as specified in ND-2330 for the base material to be welded or repaired. Where two materials are to be joined by welding, and have different fracture toughness requirements, the test requirements and acceptance standards of either material may be used for the weld metal, except where otherwise specified by NCA-1280 or other parts of this Section.

(c) A Welding Procedure Specification qualified to the impact testing requirements of Subsection NB, NC, or NE may be accepted as an alternative to the Welding Procedure Specification impact testing requirements of this Subsection. Use of this alternative shall be identified on the Welding Procedure Qualification Record.

ND-4335.2 Impact Tests of Heat Affected Zone

(a) Charpy V-notch tests of the heat affected zone of the welding procedure qualification test assembly are required whenever the thickness of the weld exceeds $\frac{5}{8}$ in. and either of the base materials require impact testing in accordance with the rules of ND-2310. Exemption of base materials by ND-2311(a)(8) does not apply to the welding procedure qualification heat affected zone or unaffected base material for such materials. The only exceptions to the requirements are the following:

(1) the qualification for welds in P-Nos. 1 and 3 and SA-336 F12 materials that are postweld heat treated and are made by any process other than electroslag, electrogas, or thermit;

(2) the qualification for weld deposit cladding or hard-facing on any base material.

(b) Impact testing of the procedure qualification test heat affected zone, where required by ND-4335, shall be conducted in accordance with (1) through (3) below, and (c) below, if applicable.

(1) For tests of welding procedure qualifications for materials that require testing in accordance with ND-2331, the three Charpy V-notch heat affected zone specimens and three Charpy V-notch unaffected base material specimens shall be tested at a temperature in accordance with ND-2331(a). The Charpy V-notch impact test of the unaffected base material shall meet the toughness value requirements of Table ND-2331(a)-1

Page 242

or Table ND-2331(a)-2. If the average toughness value of the three heat affected zone specimens is equal to or greater than the average toughness value of the unaffected base material Charpy V-notch specimens, the qualification test shall be considered acceptable, and the values and testing temperature shall be recorded on the Welding Procedure Qualification Record.

(2) If the heat affected zone Charpy V-notch average toughness value of (b)(1) above is less than the unaffected base material value and the qualification test meets the other criteria of acceptance, the Charpy V-notch test results may be recorded on the Welding Procedure Qualification Record. Data shall then be obtained, as specified in (3) below, to provide an additive temperature for the adjustment of the lowest service temperature (LST) of the base material that is to be welded in production with the welding procedure that is being qualified. Alternatively, the welding procedure qualification may be rewelded and retested.

(3) The data for use in (b)(2) above shall be developed by performing additional Charpy V-notch tests on either the welding procedure qualification test heat affected zone or the unaffected base material, or both, at temperatures which provide toughness values that meet or exceed those required for the yield strength and thickness of the material to be welded in production. The average toughness data for the heat affected zone and unaffected base material shall be plotted on a property temperature chart. The temperature at which these two sets of data exhibit a common acceptable value of toughness for the production base material shall be determined. The determined temperature for the unaffected base material shall be subtracted from the similarly determined temperature for the heat affected zone. This difference, if a positive number, shall be used in (b)(2) above as the adjustment temperature. The welding procedure adjustment temperature shall be added to the highest LST established by the tests of ND-2331 for all of the base material to be welded by this procedure in production. If the temperature difference is zero or a negative number, no adjustment is required for the base material to be welded in production, and the minimum temperature established by the tests for ND-2331 will still apply as stated in (b)(2) above. Where the actual LST is not required for the production material to be welded, for example, where a testing temperature is established by the Design Specification to determine that the material has adequate toughness to meet the requirements of Table ND-2331(a)-1 or Table ND-2331(a)-2 at the specified test temperature, the adjustment temperature determined by the curves shall be used to establish a reduction in the specified testing temperature for the production material.

The adjustment temperature shall be used to lower the specified testing temperature for any production material on which the procedure will be used.

(c) Should the unaffected base material Charpy V-notch impact test results fail to meet the applicable requirements referenced in (b)(1) above, additional unaffected base material Charpy V-notch impact tests shall be tested at higher temperatures until the applicable requirements are met. Charpy V-notch impact tests of the heat affected zone shall be tested at the same temperature at which acceptable unaffected base material properties were achieved. The rules governing the average toughness values of the heat affected zone relative to the average toughness values of the unaffected base material shall be followed as in (b)(1) through (3) above, to determine the data which are to be recorded in the Welding Procedure Qualification Record.

(d) A Welding Procedure Specification qualified to the impact testing requirements of Subsection NB, NC, or NE may be accepted as an alternative to the Welding Procedure Specification impact testing requirements of this Subsection.

ND-4336 Qualification Requirements for Built-Up Weld Deposits

Built-up weld deposits for base metal reinforcement shall be qualified in accordance with the requirements of ND-4331 to ND-4335, inclusive.

ND-4350 SPECIAL QUALIFICATION REQUIREMENTS FOR TUBE-TO-TUBESHEET WELDS

ND-4351 General Requirements

The welding procedure for tube-to-tubesheet welds shall be set up as a new procedure specification and shall be completely requalified when any of the changes listed below are made in the procedure. Changes other than those given may be made in a procedure without the necessity of requalification, provided the procedure specification is amended to show these changes.

ND-4352 Essential Variables for All Welding Processes

Essential variables for all welding processes shall be as stipulated in (a) through (k) below:

(a) a change from one welding process to any other welding process or combination of welding processes;

(b) a change in the P-Number classification of tube material in Section IX, QW-422. A separate qualification

Page 243

is required for each tube material which is not included under any P-Number.

(c) a change in the P-Number of the tubesheet base material. The base material may be a homogeneous material or a cladding material of wrought type or weld overlay type. If welding is performed between the tube and cladding, the cladding shall be considered the base material. A separate qualification is required for welding tubes to base material or cladding material which is not included under any P-Number.

(d) changes in the weld metal analysis of the deposited weld metal as given in (1) or (2) below:

(1) a change from any A-Number in Section IX, QW-422 to any other A-Number or to any F-Number in QW-432 or to any analysis not listed in the tables, except that each AISI type similar to A-No. 7 or A-No. 8 of QW-422 shall require separate qualification;

(2) a change from any F-Number in QW-432 to any other F-Number or to any A-Number in QW-422 or to any analysis not listed in the tables;

(e) for tubes of specified wall thickness of 0.100 in. or less, an increase or decrease of 10% of specified wall thickness or specified diameter;

(f) for specified wall thicknesses greater than 0.100 in., only one qualification test is required;

(g)

- (g) a decrease of 10% or more in the specified width of the ligament between tube holes when the specified width of the ligament is less than the greater of $\frac{3}{8}$ in. (10 mm) or three times the specified tube wall thickness;
- (h) the addition of other welding positions than those already qualified (Section IX, QW-461.1);
- (i) a change in the specified preheating temperature range;
- (j) a change in the specified postweld heat treating temperature;
- (k) a change from multiple pass to single pass or vice versa.

ND-4353 Essential Variables for Shielded Metal-Arc Welding

An additional essential variable for shielded metal-arc welding is an increase in electrode diameter.

ND-4354 Essential Variables for Gas Tungsten-Arc and Gas Metal-Arc Welding

Additional essential variables for gas tungsten-arc and gas metal-arc welding are as given in (a) through (f) below:

- (a) a change in the configuration of the tubesheet at the tube hole edges, including the addition or omission of preplaced metal inserts;
- (b) a change in the size or shape of preplaced metal inserts;
- (c) a change from one shielding gas to another shielding gas or to a mixture of shielding gases;
- (d) when using mixed shielding gas, a change of $\pm 25\%$ or 5 cu ft/hr (0.14 m³/hr), whichever is the larger, in the rate of flow of the minor gas constituent;
- (e) for gas tungsten-arc welding process, the addition or omission of filler metal;
- (f) a change in the nominal diameter of the filler metal.

ND-4355 Essential Variables for Explosive Welding

Additional essential variables for explosive welding are as given in (a) through (e) below:

- (a) an increase or decrease in the specified tube wall thickness or diameter of 10% for all diameters and wall thicknesses instead of the provision of ND-4352(e);
- (b) a change in the method of pressure application;
- (c) a change in the type of explosive or a change in energy content of $\pm 10\%$;
- (d) a change of $\pm 10\%$ in the placement of the charge from the tubesheet face;
- (e) a change in the specified clearance between the tube and the tubesheet of $\pm 10\%$.

ND-4356 Test Assembly

The procedure qualification shall be made on a test assembly which simulates the conditions to be used in production with respect to the tube hole pattern and the essential variables listed in ND-4352 through ND-4354. In addition, the thickness of the tubesheet in the test assembly shall be as thick as the production tube sheet, except it need not exceed 2 in. (51 mm). The minimum required number of weld joints shall be 10.

ND-4357 Examination of Test Assembly

The assembly shall be examined by a liquid penetrant method in accordance with the requirements of ND-5110 and shall meet the acceptance standards of ND-5350. Following this, the assembly shall be sectioned longitudinally through each tube. The thickness of the assembly may be reduced to $\frac{1}{2}$ in. (13 mm) prior to this sectioning. The four faces of each tube exposed by sectioning shall be polished and etched with a suitable etchant and shall be visually examined for

cracks. The weld throat minimum leakage path shall be not less than two-thirds of the specified tube wall thickness, and

cracks. The weld throat minimum leakage path shall be not less than two-thirds of the specified tube wall thickness, and the weld shall be free from cracks on visual examination with $\times 10$ magnification.

ND-4358 Performance Qualification

ND-4358.1 Welders.

The requirements for the performance qualification test for welders shall be the same as those for the procedure qualification, except that the minimum required number of tubes in the test assembly shall be six.

ND-4358.2 Welding Operators.

The requirements for the performance qualification test for welding operators (automatic weld process) shall be the same as those for the procedure qualification except that:

- (a) the essential variables for performance qualification are those detailed in ND-4352(a), (b), (c), (d), and (h);
- (b) the minimum required number of tubes in the test assembly shall be six.

ND-4400 RULES GOVERNING MAKING, EXAMINING, AND REPAIRING WELDS

ND-4410 PRECAUTIONS TO BE TAKEN BEFORE WELDING

ND-4411 Identification, Storage, and Handling of Welding Materials

Each Certificate Holder is responsible for control of the welding electrodes and other materials which are used in the fabrication and installation of components (ND-4120). Suitable identification, storage, and handling of electrodes, flux, and other welding material shall be maintained. Precautions shall be taken to minimize absorption of moisture by electrodes and flux.

ND-4412 Cleanliness and Protection of Welding Surfaces

The method used to prepare the base metal shall leave the weld preparation with reasonably smooth surfaces. The surfaces for welding shall be free of scale, rust, oil, grease, and other deleterious material. The work shall be protected from deleterious contamination and from rain, snow, and wind during welding. Welding shall not be performed on wet surfaces.

ND-4420 RULES FOR MAKING WELDED JOINTS

ND-4421 Backing Rings

Backup plates and backing rings which remain in place, and compression rings or stiffeners of storage tanks such as angles, bars, and ring girders may be used. Their materials shall be compatible with the base metal, but spacer pins shall not be incorporated into the welds.

ND-4422 Peening

Controlled peening may be performed to minimize distortion. Peening shall not be used on the initial layer root of the weld metal or on the final layer unless the weld is postweld heat treated.

ND-4423 Double Welded Joints, Single Welded Joints, and Plug Welds

ND-4423.1 Double Welded Joints.

Before applying weld metal on the second side to be welded, the root of full penetration double welded joints shall be prepared by suitable methods such as chipping, grinding, or thermal gouging, except for those processes of welding by which proper fusion and penetrations are otherwise obtained and demonstrated to be satisfactory by welding procedure qualifications.

ND-4423.2 Single Welded Joints.

Where single welded joints are used, particular care shall be taken in aligning and separating the components to be joined so that there will be complete penetration and fusion at the bottom of the joint for its full length.

ND-4423.3 Plug Welds.

In welding plug welds, a fillet around the bottom of the hole shall be deposited first.

[98]

ND-4424 Surfaces of Welds

As-welded surfaces are permitted, except for inertia and continuous drive friction welding where the flash shall be removed to sound metal. For piping, the appropriate stress intensification factors given in Table ND-3672(b)-1 shall be applied. However, the surface of welds shall be sufficiently free from coarse ripples, grooves, overlaps, abrupt ridges, and valleys to meet the requirements of (a) through (e) below.

(a) The surface condition of the finished weld shall be suitable for the proper interpretation of radiographic and other required nondestructive examination of the weld. In those cases where there is a question regarding

Page 245

the surface condition on the interpretation of a radiographic film, the film shall be compared to the actual weld surface for interpretation and determination of acceptability.

(b) Reinforcements are permitted in accordance with ND-4426.1 for vessels, pumps, and valves, and with ND-4426.2 for piping.

(c) Undercuts shall not exceed $\frac{1}{32}$ in. (0.8 mm) and shall not encroach on the required section thickness.

(d) Concavity on the root side of a single welded circumferential butt weld is permitted when the resulting thickness of the weld meets the requirements of ND-3000.

(e) If the surface of the weld requires grinding to meet the above criteria, care shall be taken to avoid reducing the weld or base material below the required thickness.

(f) For inertia and continuous drive friction welding, the weld upset shall meet the specified amount within $\pm 10\%$.

[98]

ND-4425 Welding Components of Different Diameters

When components of different diameters are welded together, there shall be a gradual transition between the two surfaces. The length of the transition may include the weld in accordance with ND-3361.

ND-4426 Reinforcement of Welds

ND-4426.1 Thickness of Weld Reinforcement for Vessels, Pumps, and Valves.

The surface of the reinforcement of all butt welded joints in vessels, pumps, and valves may be flush with the base material or may have uniform crowns. The height of reinforcement on each face of the weld shall not exceed the thickness in the following tabulation:

Nominal Thickness, in.	Maximum Reinforcement, in.
Up to 1, incl.	$\frac{3}{32}$
Over 1 to 2, incl.	$\frac{1}{8}$
Over 2 to 3, incl.	$\frac{5}{32}$
Over 3 to 4, incl.	$\frac{7}{32}$
Over 4 to 5, incl.	$\frac{1}{2}$

Over 5

$\frac{5}{16}$ ⁴

ND-4426.2 Thickness of Weld Reinforcement for Piping.

For double welded butt joints, the limitation on the reinforcement given in Column 1 of the following tabulation shall apply separately to both inside and outside surfaces of the joint. For single welded butt joints, the reinforcement given in Column 2 shall apply to the inside surface and the reinforcement given in Column 1 shall apply to the outside surface. The reinforcement shall be determined from the higher of the abutting surfaces involved.

Material Nominal Thickness, in.	Maximum Reinforcement Thickness, in.	
	Column 1	Column 2
Up to $\frac{1}{8}$ incl.	$\frac{3}{32}$	$\frac{3}{32}$
Over $\frac{1}{8}$ to $\frac{3}{16}$ incl.	$\frac{1}{8}$	$\frac{3}{32}$
Over $\frac{3}{16}$ to $\frac{1}{2}$ incl.	$\frac{5}{32}$	$\frac{1}{8}$
Over $\frac{1}{2}$ to 1, incl.	$\frac{3}{16}$	$\frac{5}{32}$
Over 1 to 2, incl.	$\frac{1}{4}$	$\frac{5}{32}$
Over 2	The greater $\frac{1}{4}$ in. or $\frac{1}{8}$ times the width of the weld, in.	$\frac{5}{32}$

ND-4427 Shape and Size of Fillet Welds

(a) Fillet welds may vary from convex to concave. Except as permitted in (b) below, the shape and size of the weld shall be in accordance with the requirements of Fig. ND-4427-1. A fillet weld in any single continuous weld may be less than the specified fillet weld dimension by not more than $\frac{1}{16}$ in. (1.6 mm), provided that the total undersize portion of the weld does not exceed 10% of the length of the weld. Individual undersize weld portions shall not exceed 2 in. (51 mm) in length. In making socket welds, a gap as shown in Fig. ND-4427-1 shall be provided prior to welding. The gap need not be present nor be verified after welding.

(b) Socket welds smaller than those specified in Fig. NC-4427-1 may be used provided the requirements of NC-3000 are met.

ND-4428 Seal Welds of Threaded Joints

Where seal welding of threaded pipe joints is performed, the exposed threads shall be either removed entirely or covered with weld metal.

ND-4430 WELDING OF ATTACHMENTS

ND-4431 Materials for Attachments

Nonpressure-retaining attachments (ND-1132.1) welded to pressure retaining components shall be of materials which meet the requirements of ND-2190.

Page 246

Page 247

FIG. ND-4427-1 FILLET AND SOCKET WELD DETAILS AND DIMENSIONS

FIG. ND-4427-1 FILLET AND SOCKET WELD DETAILS AND DIMENSIONS

Materials for pressure retaining attachments shall meet the requirements of ND-2120.

ND-4432 Welding of Structural Attachments

The rules of ND-4321 governing welding qualifications shall apply to the welding of structural attachments to pressure retaining material.

ND-4433 Structural Attachments

Structural attachments shall conform reasonably to the curvature of the surface to which they are to be attached and shall be attached by full penetration, fillet, or partial penetration continuous or intermittent welds. Figure ND-4433-1 illustrates some of the typical details for attaching structural attachments to a component using full penetration welds. Valve seats may be attached to the pressure boundary part by fillet or partial penetration welds, provided the valve seat is shouldered against the pressure boundary part.

ND-4434 Types of Permanent Structural Attachments

Internal structural supports on cladding surfaces shall be welded to the base metal and not to the cladding, except for weld overlay cladding.

ND-4435 Welding of Nonstructural and Temporary Attachments and Their Removal

(a) Nonstructural attachments (ND-1132.1) welded to the pressure retaining portion of the component need not comply with ND-2000 and may be welded with continuous or intermittent fillet or partial penetration welds, provided the requirements of (1) through (4) below are met.

(1) The welding procedure and the welders have been qualified in accordance with ND-4321.

(2) The material is identified and is compatible with the material to which it is attached.

(3) The welding material is identified and is compatible with the materials joined.

(4) The welds are postweld heat treated when required by ND-4620.

(b) Removal of nonstructural attachments, when temporary, shall be accomplished as follows:

(1) The temporary attachment is completely removed in accordance with the procedures of ND-4211;

(2) As an alternative to (a)(4) above, postweld heat treatment may be deferred until after removal of the attachment.

ND-4436 Installation of Attachments to Piping Systems After Testing

Attachments may be welded to the piping system after performance of the pressure test provided that:

(a) the welds do not require PWHT as provided in ND-4622.7;

(b) welds shall be restricted to fillet welds not exceeding $\frac{3}{8}$ in. (10 mm) throat thickness and to full penetration welds attaching materials not exceeding $\frac{1}{2}$ in. (13 mm) in thickness;

(c) welds shall not exceed a total length of 24 in. (610 mm) for fillet welds or 12 in. (305 mm) for full penetration welds;

(d) welds shall be examined as required by ND-5000.

ND-4437 Attachments of Stiffener Rings

ND-4437.1 General Requirements.

All permanent and temporary attachments of stiffener rings to shells, including tack welds, shall be made by qualified welders using qualified welding procedures.

ND-4437.2 Attachment of Stiffening Rings to Shell

(a) Stiffening rings, when used, may be placed on the inside or outside of a vessel and shall be attached to the shell by welding or bolting. The ring shall be in contact with the shell.

(b) Stiffening rings may be attached to the shell by either continuous or intermittent welding. The total length of the intermittent welding on each side of the stiffening ring shall be:

- (1) not less than one-half the outside circumference of the component for rings on the outside; and
- (2) not less than one-third of the circumference of the vessel for rings on the inside.

Acceptable arrangements and spacings of intermittent welds are shown in Fig. ND-4437.2(b)-1. Welds on opposite sides of the stiffener may be either staggered or in-line as indicated.

(c) All welding of stiffening rings shall comply with the requirements of this Subsection. In areas where a corrosion allowance is specified in the Design Specification, stiffening rings shall be attached to the shell with a continuous fillet weld, seal weld, or full penetration weld.

Page 248

Page 249

GENERAL NOTE:
The welds may be partial penetration or fillet welds.

FIG. ND-4433-1 TYPES OF ATTACHMENT WELDS

FIG. ND-4433-1 TYPES OF ATTACHMENT WELDS

**FIG. ND-4437.2(b)-1 SOME ACCEPTABLE

FIG. ND-4437.2(b)-1 SOME ACCEPTABLE METHODS OF ATTACHING STIFFENING RINGS TO SHELLS OF CYLINDRICAL VESSELS SUBJECTED TO EXTERNAL PRESSURE

ND-4450 REPAIR OF WELD METAL DEFECTS

ND-4451 General Requirements

Defects in weld metal detected by the examinations required by ND-5000, or by the tests of ND-6000, shall be eliminated and repaired when necessary.

ND-4452 Elimination of Surface Defects

Weld metal surface defects may be removed by grinding or machining and not repaired by welding, provided that the requirements of (a), (b), and (c) below are met.

(a) The remaining thickness of the section is not reduced below that required by ND-3000.

(b) The depression, after defect elimination, is blended uniformly into the surrounding surface.

(c) The area is examined by a magnetic particle or liquid penetrant method in accordance with ND-5110 after blending and meets the acceptance standards of ND-5300 to ensure that the defect has been removed or the indication reduced to an acceptable limit. Defects detected by visual or volumetric method and located on an interior surface need only be reexamined by the method which initially detected the defect when the interior surface is inaccessible for surface examination.

ND-4453 Requirements for Making Repairs of Welds

Excavations in weld metal, when repaired by welding, shall meet the requirements of the following subparagraphs.

ND-4453.1 Defect Removal.

Defects may be removed by mechanical means or by thermal gouging processes. The area prepared for repair shall be examined by a liquid penetrant or magnetic particle method in accordance with ND-5110 and meet the acceptance standards of ND-5340 or ND-5350. This examination is not required where defect elimination removes the full thickness of the weld and where the backside of the weld joint is not accessible for removal of examination materials.

ND-4453.2 Requirements for Welding Material, Procedures, and Welders.

The weld repair shall be made using welding materials, welders, and welding procedures qualified in accordance with ND-4125 and ND-4300.

ND-4453.3 Blending of Repaired Areas.

After repair the surface shall be blended uniformly into the surrounding surface.

ND-4453.4 Examination of Repair Welds

(a) The examination of a weld repair shall be repeated as required for the original weld, except that it need only be reexamined by the liquid penetrant or magnetic particle method when the unacceptable indication was originally detected by the liquid penetrant or magnetic particle method and when the repair cavity does not exceed the following:

(1) $\frac{1}{3}t$ for $t \leq \frac{3}{4}$ in. (19 mm)

(2) $\frac{1}{4}$ in. (6 mm) for $\frac{3}{4}$ in. (19 mm) $< t \leq 2\frac{1}{2}$ in. (64 mm)

(3) the lesser of $\frac{3}{8}$ in. (10 mm) or $10\%t$ for $t > 2\frac{1}{2}$ in. (64 mm)

where t equals the thickness of the weld.

(b) When repairs to welds joining P-No. 1 and P-No. 3 materials require examination by radiography as required in (a)

above, but construction assembly prevents meaningful radiographic examination, ultrasonic examination may be substituted, provided:

(1) the weld had been previously radiographed and met the applicable acceptance standards:

Page 250

(2) the ultrasonic examination is performed using a procedure in accordance with Section V, Article 5 to the acceptance standards of ND-5330;

(3) the substitution is limited to Category A and B welds in vessels and similar type welds in other items.

The absence of suitable radiographic equipment is not justification for the substitution.

ND-4453.5 Heat Treatment of Repaired Areas.

The area shall be heat treated in accordance with ND-4620.

ND-4460 WELDED TEST PLATES

(a) For welded vessels constructed of Type 405 material which are not postweld heat treated, welded test plates shall be made to include material from each melt of plate steel used in the vessel. Plates from two different melts may be welded together and be represented by a single test plate.

(b) From each welded test plate there shall be taken two face bend test specimens as prescribed in Section IX, QW-161.2 and shall meet the requirements of Section IX, QW-162 and QW-163.

ND-4470 WELDED STAYED CONSTRUCTION

Welded staybolts must be attached using details similar to those shown in Fig. ND-4470-1, where t equals the nominal thickness of the inner stayed plate.

ND-4500 BRAZING

ND-4510 RULES FOR BRAZING

ND-4511 Where Brazing May Be Used

(a) Brazing is permitted for the attachment of tubes to tubesheets and as specified in ND-3671.6. Appurtenances and piping with outside diameter equal to that of NPS 4 and less may be fabricated using brazed joints in accordance with Fig. ND-4511-1.

(b) Valves with inlet piping connections of NPS 4 (DN 100) and less may have seats brazed to the valve body or bonnet, provided the seat is shouldered against the pressure boundary part.

ND-4512 Brazing Material

Where brazing is permitted, the brazing filler material and fluxes shall conform to the rules covering identification in ND-2150 and to the requirements of (a), (b), and (c) below.

(a) The filler material used in brazing shall be a nonferrous metal or alloy with a solidus temperature above 800°F (427°C) and at least 500°F (278°C) above the highest temperature of the joint in service.

(b) The filler material shall melt and flow freely by capillary action within the desired temperature range, and in conjunction with a suitable flux or controlled atmosphere the filler material shall wet and adhere to the surfaces to be joined.

(c) Fluxes that are fluid and chemically active at the brazing temperature shall be used, when necessary, to prevent oxidation of the filler metal and the surfaces to be joined, and to promote free flowing of the filler material.

ND-4520

ND-4520 BRAZING QUALIFICATION REQUIREMENTS

ND-4521 Brazing Procedure and Performance Qualifications

Qualification of the brazing procedure to be used and of the performance of brazers and brazing operators is required and shall comply with the requirements of Section IX, except that validation of the procedure qualification per QB-451.5 Note (1) is not required for the furnace brazing of seat rings to bodies or bonnets of valves having inlet piping connections of 4 in. (DN 100) nominal size and less. When the Design Temperature is greater than 200°F (93°C), tension testing shall be performed at the Design Temperature.

ND-4522 Brazing Requalification Requirements

In addition to the requirements of Section IX, the brazing procedure shall be set up as a new procedure specification and shall be completely requalified when the construction of the brazed components includes reheating of any portion of the completed brazed joint to a temperature that is within 300°F (167°C) of the solidus temperature of the filler metal.

ND-4530 FITTING AND ALIGNING OF PARTS TO BE BRAZED

Parts to be joined by brazing shall be fitted, aligned, and retained in position during the brazing operation

Page 251

Page 252

Typical Forms of Welded Staybolts

Use of Plug and Slot Welds for Staying Plates

FIG. ND-4470-1 WELDED STAYED CONSTRUCTION

within the tolerances specified in the brazing procedure specification. Brazed joints shall be assembled in a sequence which will permit the maximum number of joints to be visually examined on both sides of the joint after brazing.

- t = thickness of part penetrated
 t_n = nominal thickness of connecting part
 d = outside diameter of part B
 c = clearance or interference between mating parts and shall be in accordance with the brazing procedure specification
 Z = depth of engagement and shall be the lesser of $3t_n$ or d , but in no case less than 1/4 in.

GENERAL NOTES:

- (a) Part A shall be attached to a component in accordance with the requirements for the component proper.
 (b) Part B shall be attached either to part A or to another part B by the joints shown above, or in accordance with the requirements of the component proper.
 (c) Grooves for preplaced filler metal are permitted, provided the reduction in cross section due to the grooves is considered in the design.

FIG. ND-4511-1 BRAZED CONNECTIONS FOR APPURTENANCES AND PIPING, 4 in. NOMINAL PIPE SIZE AND LESS

FIG. ND-4511-1 BRAZED CONNECTIONS FOR APPURTENANCES AND PIPING, 4 in. NOMINAL PIPE SIZE AND LESS

ND-4540 EXAMINATION OF BRAZED JOINTS

The completed brazed joints shall be visually examined on all accessible surfaces in accordance with ND-5360.

ND-4600 HEAT TREATMENT

ND-4610 WELDING PREHEAT REQUIREMENTS

ND-4611 When Preheat Is Necessary

The need for and temperature of preheat are dependent on a number of factors, such as the chemical analysis, degree of restraint of the parts being joined, elevated temperature, physical properties, and material thicknesses. Some practices used for preheating are given in Appendix D as a general guide for the materials listed by P-Numbers of Section IX. It is cautioned that the preheating suggested in Appendix D does not necessarily ensure satisfactory completion of the welded joint and that the preheating requirements for individual materials within the P-Number listing may be more or less restrictive. The Welding Procedure Specification for the material being welded shall specify the minimum preheating requirements under the welding procedure qualification requirements of Section IX.

ND-4612 Preheating Methods

Preheat for welding or thermal cutting, when employed, may be applied by any method which does not harm the base material or any weld metal already applied or which does not introduce deleterious material into the welding area.

ND-4613 Interpass Temperatures

Consideration shall be given to the limitations of interpass temperatures for quenched and tempered material to avoid detrimental effects on the mechanical properties.

ND-4620 POSTWELD HEAT TREATMENT

ND-4621 Heating and Cooling Methods

Postweld heat treatment (PWHT) may be accomplished by any suitable methods of heating and cooling, provided the required heating and cooling rates, metal temperature, metal temperature uniformity, and temperature control are maintained.

ND-4622 PWHT Time and Temperature Requirements

ND-4622.1 General Requirements.⁴

Except as otherwise permitted in ND-4622.7, all welds, including repair welds, shall be postweld heat treated. During postweld heat treatment, the metal temperature shall be maintained within the temperature range and for the minimum holding time specified in Table ND-4622.1-1, except as otherwise permitted in ND-4622.4(d). For P-No. 11A, Group 1 material, the complete component shall be postweld heat treated within the temperature range specified in Table ND-4622.1-1 and the provisions of ND-4624.2 and ND-4624.3 shall not be applied. P-Number groups in Table ND-4622.1-1 are in accordance with Section IX, QW-420. Except as provided in ND-4624.3, PWHT shall be performed in temperature-surveyed and -calibrated furnaces, or PWHT shall be performed with thermocouples in contact with the material or attached to blocks in contact with the material. In addition, the requirements of the following subparagraphs shall apply.

ND-4622.2 Time-Temperature Recordings.

Time-temperature recordings of all postweld heat treatments shall be made available for review by the Inspector. Identification on the time-temperature recording shall be to the weld, item, part, or component. A summary of the

Identification on the time-temperature recording shall be to the weld, item, part, or component. A summary of the time-temperature recording may be provided for permanent records in accordance with NCA-4134.17.

4 Any postweld heat treatment time which is anticipated to be applied to the material or item after it is completed shall be specified in the Design Specification. The Certificate Holder shall include this time in the total time at temperature specified to be applied to the test specimens.

ND-4622.3 Definition of Nominal Thickness Governing PWHT.

Nominal thickness in Table ND-4622.7(b)-1 is the thickness of the weld, the pressure retaining material for structural attachment welds or the thinner of the pressure retaining materials being joined, whichever is least. It is not intended that nominal thickness include material provided for forming allowance, thinning, or mill overrun when the excess material does not exceed $\frac{1}{8}$ in. (3.2 mm). For fillet welds the

NOTES:

- (1) Exemptions to the mandatory requirements of this Table are defined in ND-4622.7.
(2) All temperatures are metal temperatures.

TABLE ND-4622.1-1 MANDATORY REQUIREMENTS FOR POSTWELD HEAT TREATMENT OF WELDS¹

nominal thickness is the throat thickness, and for partial penetration and material repair welds the nominal thickness is the depth of the weld groove or preparation.

TABLE ND-4622.4(c)-1 ALTERNATIVE HOLDING TEMPERATURES AND TIMES¹

Material P-Nos.	Alternative Minimum Holding Temperatures, °F	Alternative Minimum Holding Times
1, 3, 9A Gr.1, 9B Gr.1	1050	2 hr/in. thick
1, 3, 9A Gr.1, 9B Gr.1	1000	4 hr/in. thick

NOTE:

(1) All other requirements of ND-4622 shall apply.

TABLE ND-4622.4(c)-1 ALTERNATIVE HOLDING TEMPERATURES AND TIMES¹

ND-4622.4 Holding Times at Temperature

(a) The holding time at temperature as specified in Table ND-4622.1-1 shall be based on the nominal thickness of the weld. The holding time need not be continuous. It may be an accumulation of the times of multiple postweld heat treat cycles.

(b) Holding time at temperature in excess of the minimum requirements of Table ND-4622.1-1 may be used, provided that specimens so heat treated are tested in accordance with ND-2200, ND-2400, and ND-4300.

(c) Alternatively, when it is impractical to postweld heat treat at the temperature range specified in Table ND-4622.1-1, it is permissible to perform the postweld heat treatment of certain materials at lower temperatures for longer periods of time in accordance with Table ND-4622.4(c)-1 and (1), (2), and (3) below.

(1) Except for P-No. 1 materials, when welds in the materials listed in Table ND-4622.4(c)-1 are to be postweld heat treated at these lower minimum temperatures, the impact test specimens for the welding procedure qualification required by ND-4300 shall be made using the same minimum temperatures and increased minimum holding time. Welding procedures, qualified at the temperature range and minimum holding time specified in Table ND-4622.1-1 and at the lower minimum temperature and increased minimum holding time permitted by Table ND-4622.4(c)-1, are

and at the lower minimum temperature and increased minimum holding time permitted by Table ND-4622.4(c)-1, are also qualified for any temperature in between. When such an in-between temperature is used, the minimum holding time shall be interpolated from Table ND-4622.1-1 and the alternative requirements of Table ND-4622.4(c)-1.

(2) Except for P-No. 1 materials, when welds in the materials listed in Table ND-4622.4(c)-1 are to be postweld heat treated at these lower minimum temperatures, the welding material certification required by ND-2400 shall be made using the same minimum temperature and increased minimum holding times. Welding material certified at the temperature range and minimum holding time specified in Table ND-4622.1-1 and at the lower minimum temperatures and increased minimum holding times permitted by Table ND-4622.4(c)-1 are also certified for any temperature in between.

(3) Base material certified in accordance with ND-2200 may be postweld heat treated at the lower minimum temperatures and increased minimum holding times without recertification. Postweld heat treatment at these lower minimum temperatures and increased minimum holding times may also be the tempering operation, provided a higher tempering temperature is not required by the material specification.

ND-4622.5 PWHT Requirements When Different P-Number Materials Are Joined.

When pressure retaining materials of two different P-Number groups are joined by welding, the applicable postweld heat treatment shall be that specified in Table ND-4622.1-1 for the material requiring the higher PWHT temperature range.

ND-4622.6 PWHT Requirements for Nonpressure-Retaining Parts.

When nonpressure-retaining material is welded to pressure retaining material, the postweld heat treatment temperature range of the pressure retaining material shall control.

ND-4622.7 Exemptions to Mandatory Requirements.

Postweld heat treatment in accordance with this Subarticle is not required for (a) through (d) below:

(a) nonferrous material⁵

(b) welds exempted in Table ND-4622.7(b)-1;

(c) welds subjected to temperatures above the PWHT temperature range specified in Table ND-4622.1-1, provided the Welding Procedure Specification is qualified in accordance with Section IX and the base material and the deposited weld material have been heat treated at the higher temperatures;

(d) welds connecting nozzles to components or branch to run piping, provided the requirements in ND-4622.8 are met;

(e) weld repairs to P-No. 3 material in vessels, provided the requirements of ND-4622.9 are met.

⁵ PWHT shall be performed only by agreement between the Owner and the Certificate Holder, except for casting SB-148 alloy CD954. Agreement shall cover time, temperature, and method of PWHT.

11A Gr. 4	All welds in material $\frac{1}{2}$ in. and less	$\frac{1}{2}$ in. or less	...	250

NOTES:

(1) The exemptions noted in this Table do not apply to the following:

(a) electron beam welds in ferritic materials of $\frac{1}{8}$ in. in thickness;

(b) inertia and friction welds in material of any thickness of P-No. 3, P-No. 4, P-No. 5, P-No. 7 (except for Types 405 and 410 S), P-No. 10, and P-No. 11 materials.

(2) Maximum process heat input = 150,000 J/in. The maximum resulting hardness of the heat affected zone in the procedure qualification test plate shall not exceed 35 Rc.

(3) Intermediate postweld soak at not less than 200°F for 2 hr minimum.

(4) Intermediate postweld soak at not less than 300°F for 2 hr minimum.

(5) Where the thickness of material is identified in the Type of Weld column, it is the thickness of the base material at the welded joint.

(6) Carbon level of the pressure retaining materials being joined.

[98]

TABLE ND-4622.7(b)-1 (CONT'D) EXEMPTIONS TO MANDATORY PWHT¹

ND-4622.8 Requirements for Exempting PWHT of Nozzles to Component Welds and Branch-to-Run Piping Welds.

Welds connecting nozzles or branch piping of P-No. 1 materials to components or run piping of P-No. 1 or P-No. 3 materials that are not exempted from PWHT in Table ND-4622.7(b)-1 need not be given a postweld heat treatment if the requirements of (a) below are met for partial penetration and (b) below are met for full penetration welds.

(a) The partial penetration welds are made with A-No. 8 or non-air-hardening nickel-chromium-iron weld metal after:

(1) the ferritic materials to be joined are buttered or built up with A-No. 8 or non-air-hardening nickel-chromium-iron weld metal having a minimum thickness of $\frac{1}{4}$ in., and

(2) the heat affected zones of the buttered or built-up ferritic materials are postweld heat treated in accordance with ND-4620, without the PWHT exemptions being applied, prior to making the final welds.

(b) The full penetration welds are made with A-No. 1 or A-No. 2 weld metal, provided that:

(1) the component or run pipe is built up or buttered in the area of the attachment with A-No. 1 or A-No. 2 metal having a minimum thickness of $\frac{1}{4}$ in.;

(2) the A-No. 1 or A-No. 2 weld metal buildup or buttering is postweld heat treated in accordance with ND-4620 for P-No. 1 or P-No. 3 materials without the PWHT exemptions being applied;

(3) the welds do not penetrate through the component or run pipe thickness;

(4) weld metal with A-No. 1 or A-No. 2 analysis is used to join the nozzle or branch pipe of P-No. 1 material to the weld buildup or buttering;

(5) the nominal thickness of the weld joining the nozzle or branch pipe to the component or run pipe does not exceed $1\frac{1}{2}$ in. (38 mm), and the maximum reported carbon content of the nozzle or branch piping connection does not exceed 0.30%;

(6) a 200°F (93°C) minimum heat is maintained during welding whenever the nominal thickness of the weld exceeds:

(a) $1\frac{1}{4}$ in. (32 mm) and the maximum reported carbon content of the material of the nozzle or branch pipe is 0.30% or less; or

(b) $\frac{3}{4}$ in. (19 mm) and the maximum reported carbon content of material of the nozzle or branch pipe connection exceeds 0.30%.

ND-4622.9 Weld Repair to Vessels.

Limited weld repairs to vessels of P-No. 3 material and A-No. 1, 2, 10, or 11 weld filler metal (Section IX, QW-422) may be made without PWHT or after the final PWHT, provided the following requirements are met.

(a) *Examination of Area to Be Repaired.* Before a repair is made, the area shall be examined by magnetic particle or liquid penetrant method in accordance with ND-5110 and this Subsection and shall meet the acceptance standards of ND-5340 or ND-5350, as appropriate.

(b) *Maximum Extent of Repairs.* A repair shall not exceed 10 sq in. (6452 mm²) in surface area and shall not be greater in depth than 50% of the base metal or weld thickness or $\frac{1}{2}$ in. (13 mm), whichever is less.

(c) *Repair Welding Procedure*

(1) The repairs shall be made using one or more procedures and welders qualified in accordance with Section IX using the shielded metal arc process and low hydrogen covered electrodes.

(2) The largest electrode diameter shall be $\frac{5}{32}$ in. (4 mm), and the bead width shall not exceed four times the electrode diameter.

(3) The repair weld shall be made with a minimum of two layers of weld metal. The last layer shall be limited or ground off so that the weld surface does not extend above the base metal a greater distance than that allowed for reinforcement of butt welds.

(4) A preheat and interpass temperature of 300°F (149°C) minimum shall be used.

(d) *Examination of Repair Welds.* Following the repair and when the area has reached ambient temperature, the area shall again be examined by magnetic particle methods and accepted in accordance with ND-4622.9(a).

ND-4623 PWHT Heating and Cooling Rate Requirements

Above 800°F (427°C) the rate of heating and cooling in any hourly interval shall not exceed 400°F (222°C) divided by the maximum thickness in inches of the material being heat treated, but shall not exceed 400°F (222°C) and need not be less than 100°F (56°) in any hourly interval. During the heating and cooling period there shall not be a greater variation in temperature than 250°F (139°C) within any 15 ft (4.6 mm) interval of weld length. The exceptions of (a) and (b) below are permitted.

(a) P-No. 6 material may be cooled in air from the PWHT holding temperature specified in Table ND-4622.1-1.

(b) For P-No. 7 material the cooling rate at temperatures above 1200°F (649°C) shall not exceed 100°F/hr (56°C), after which the rate of cooling shall be sufficiently rapid to prevent embrittlement.

Page 259

ND-4624 Methods of Postweld Heat Treatment

The postweld heat treatment shall be performed in accordance with the requirements of one of the following subparagraphs.

ND-4624.1 Furnace Heating - One Heat.

Heating the component or item in a closed furnace in one heat is the preferred procedure and should be used whenever practical. The furnace atmosphere shall be controlled so as to avoid excessive oxidation, and direct impingement of flame on the component or item is prohibited.

ND-4624.2 Furnace Heating - More Than One Heat.

The component or item may be heated in more than one heat in a furnace, provided the furnace atmosphere control requirements of ND-4624.1 apply and overlap of the heated sections of the component or item is at least 5 ft (1.5 m). When this procedure is used, the portion of the component or item outside the furnace shall be shielded so that the temperature gradient is not harmful. The cross section where the component or item projects from the furnace shall not intersect a nozzle or other structural discontinuity.

ND-4624.3 Local Heating.

Welds may be locally postweld heat treated when it is not practical to heat treat the entire component or item. Local postweld heat treatment shall consist of heating a circumferential band around the component or item at temperatures within the ranges specified in this Subarticle. The minimum width of the controlled band at each side of the weld, on the face of the greatest weld width, shall be the thickness of the weld or 2 in. (51 mm), whichever is less. The temperature of the component or item from the edge of the controlled band outward shall be gradually diminished so as to avoid harmful thermal gradients. This procedure may also be used for postweld heat treatment after repairs.

ND-4624.4 Heating Components Internally.

The component or item may be heated internally by any appropriate means and with adequate indicating and recording temperature devices to aid in the control and maintenance of a uniform distribution of temperature in the component or item. Previous to this operation, the component or item shall be fully enclosed with insulating material.

ND-4630 HEAT TREATMENT OF WELDS OTHER THAN THE FINAL POSTWELD HEAT TREATMENT

The holding temperature, the time at temperature, the heating rate, and the cooling rate need not conform to the requirements of this Article for heat treatments other than the final postweld heat treatment.

ND-4650 HEAT TREATMENT AFTER BENDING OR FORMING FOR PIPE, PUMPS, AND

VALVES

ND-4651 Conditions Requiring Heat Treatment After Bending or Forming

(a) Ferritic alloy steel pipe or formed portions of pumps or valves that have been heated for bending or other forming operations shall receive a heat treatment in accordance with ND-4620, a full anneal, a normalizing and tempering treatment, or a quenching and tempering treatment.

(b) Carbon steel pipe or formed portions of pumps or valves with a wall thickness greater than $\frac{3}{4}$ in. (19 mm) included in group P-No. 1 in Section IX that have been cold bent or formed shall receive heat treatment in accordance with ND-4620.

(c) Ferritic alloy pipe or formed portions of pumps or valves with an outside diameter greater than 4 in. (102 mm) and a wall thickness greater than $\frac{1}{2}$ in. (13 mm) included in groups P-No. 3 through P-No. 5 in Section IX that have been cold bent or formed shall require a heat treatment in accordance with ND-4620.

ND-4652 Exemptions From Heat Treatment After Bending or Forming

If the conditions described in (a) through (d) below are met, heat treatment after bending or forming is not required.

(a) Carbon steel pipe or portions of pumps and valves that have been bent or formed at a temperature of 1650°F (900°C) or higher shall require no subsequent heat treatment, provided the requirements of ND-4213 have been met.

(b) Austenitic stainless steel pipe or portions of pumps or valves that have been heated for bending or other forming operations may be used in the as-bent condition unless the Design Specifications require a heat treatment following bending or forming.

(c) Austenitic stainless steel pipe or portions of pumps or valves that have been cold bent or formed may be used in the as-bent condition unless the Design Specifications require a heat treatment following bending or forming.

(d) Carbon steel and ferritic alloy steel pipe or portions of pumps or valves with sizes and wall thicknesses less than specified in ND-4651(b) and ND-4651(c)

Page 260

may be cold bent or formed without a heat treatment following bending.

FIG. ND-4730-1 PENETRATION ASSEMBLY

FIG. ND-4730-1 PENETRATION ASSEMBLY

ND-4660 HEAT TREATMENT OF ELECTROSLAG WELDS

Electroslag welds in ferritic material over $1\frac{1}{2}$ in. (38 mm) in thickness at the joints shall be given a grain refining heat treatment.

ND-4700 MECHANICAL JOINTS

ND-4710 BOLTING AND THREADING

ND-4711 Thread Engagement

The threads of all bolts or studs shall be engaged in accordance with the design.

ND-4712 Thread Lubricants

Any lubricant or compound used in threaded joints shall be suitable for the service conditions and shall not react unfavorably with either the service fluid or any component material in the system.

ND-4713 Removal of Thread Lubricants

All threading lubricants or compounds shall be removed from surfaces which are to be seal welded.

ND-4720 BOLTING FLANGED JOINTS

In bolting gasketed flanged joints, the contact faces of the flanges shall bear uniformly on the gasket and the gasket shall be properly compressed in accordance with the design principles applicable to the type of gasket used. All flanged joints shall be made up with relatively uniform bolt stress.

ND-4730 ELECTRICAL AND MECHANICAL PENETRATION ASSEMBLIES

(a) Electrical and mechanical penetration assemblies, except those portions performing an electrical conducting or insulating function, shall be constructed in accordance with the rules for components.

(b) Tubes or pipes of NPS 2 (DN 50) and less may be joined to a penetration assembly in accordance with the rules of ND-4350.

(c) The closing seam for the penetration assembly may be made with a multipass single lap fillet weld as shown in Fig. ND-4730-1, provided the requirements of (1) through (5) below are met.

(1) One of the heads on the penetration assembly shall meet the requirements of ND-3352.3.

(2) The penetration assembly shall not exceed 18 in. (457 mm) outside diameter.

(3) The Design Pressure of the penetration assembly shall not exceed 100 psi (690 kPa), and the Design Temperature shall not exceed 400°F (204°C).

Page 261

FIG. ND-4810(c)-1 PERMISSIBLE ATTACHMENT WELDS FOR BELLOWS

FIG. ND-4810(c)-1 PERMISSIBLE ATTACHMENT WELDS FOR BELLOWS

(4) Examination of the fillet weld shall be by the liquid penetrant method in accordance with ND-5350.

(5) The fillet weld and closure head shall meet the requirements of ND-3720(b).

ND-4800 EXPANSION JOINTS

ND-4810 FABRICATION AND INSTALLATION RULES FOR BELLOWS EXPANSION JOINTS

For bellows type expansion joints, the requirements of (a) through (f) below shall be met.

(a) All welded joints shall comply with the requirements of ND-4000.

(b) The longitudinal seam weld in the bellows shall be a butt type full penetration weld.

(c) The bellows of the expansion joint shall be attached to the welding ends or flange by circumferential welds of a butt

type having a full penetration through the thickness of the bellows portion, as shown in Fig. ND-4810(c)-1.

(d) Other than the attachment welds, no circumferential welds are permitted in the bellows elements.

(e) Prior to installation of the expansion joint in the system, weld repairs shall not be permitted on parent material of the bellows.

(f) See ND-3649.2 for general requirements applicable to fabrication and installation.

American Society Of Mechanical Engineers

SEC III D1 ND-5000

ARTICLE ND-5000 EXAMINATION

Page 263

ND-5100 GENERAL REQUIREMENTS FOR EXAMINATION

ND-5110 PROCEDURES, QUALIFICATIONS, AND EVALUATION

ND-5111 General Requirements

(a) Nondestructive examinations shall be conducted in accordance with the examination methods of Section V, except as they may be modified by the requirements of this Article. Radiographic examination shall be in accordance with Section V, Article 2, except that the geometric unsharpness shall not exceed the limits of T-285. Ultrasonic examination shall be in accordance with Section V, Article 5; magnetic particle examination shall be in accordance with Section V, Article 7; liquid penetrant examination shall be in accordance with Section V, Article 6; and leak testing shall be in accordance with Section V, Article 10.

(b) The extent of radiography shall meet the requirements of ND-3352 for the joint efficiency used in the design.

(c) The requirements for spot radiography are given in ND-5400.

(d) Nondestructive examination requirements for tanks are given in ND-5280.

(e) The examinations required by this Article or by reference to this Article shall be performed by personnel who have been qualified as required by this Article. The results of the examinations shall be evaluated in accordance with the acceptance standards of this Article.

ND-5112 Nondestructive Examination Procedures

All nondestructive examinations required by this Article shall be performed in accordance with detailed written procedures which have been proven by actual demonstration to the satisfaction of the Inspector. The procedures shall comply with the appropriate Article of Section V for the particular examination method. The digitization of radiographic film and radioscopy images shall meet the requirements of Section V, Article 2, Mandatory Appendix III, "Digital Image Acquisition, Display, and Storage for Radiography and Radioscopy." Written procedures and records of demonstration of procedure capability and personnel qualification shall be made available to the Inspector on request. At least one copy of the procedure shall be readily available to all applicable nondestructive examination personnel for reference and use.

ND-5113 Post-Examination Cleaning

Following any nondestructive examination in which examination material is applied to the piece, the piece shall be thoroughly cleaned in accordance with applicable material or procedure specifications.

ND-5120 TIME OF EXAMINATION OF WELDS AND WELD METAL CLADDING

Acceptance examinations of welds and weld metal cladding required by ND-5200 shall be performed at the times stipulated in (a) through (d) below during fabrication and installation.

(a) Radiographic examination of welds shall be performed after an intermediate¹ or final postweld heat treatment, when required, except as provided in (1) and (2) below.

(1) Radiographic examination of welds in items fabricated of P-No. 1 materials may be performed prior to any required postweld heat treatment.

1 An intermediate postweld heat treatment for this purpose is defined as a postweld heat treatment performed on a weld within a temperature range not lower than the minimum holding temperature range to which the weld shall be subjected during the final postweld heat treatment.

(2) Radiographic examination of welds in P-No. 3 materials may be performed prior to an intermediate

Page 266

or final postweld heat treatment provided the welds are ultrasonically examined after an intermediate or the final postweld heat treatment. The ultrasonic examination and acceptance standards shall be in accordance with this Article.

(b) Magnetic particle or liquid penetrant examinations of welds shall be performed after any required postweld heat treatment, except that welds in P-No. 1 material may be examined either before or after postweld heat treatment.

(c) All dissimilar metal weld joints, such as in austenitic or high nickel to ferritic material or using austenitic or high nickel alloy filler metal to join ferritic materials which penetrate the wall, shall be examined after final postweld heat treatment.

(d) The magnetic particle or liquid penetrant examination of weld surfaces that are to be covered with weld metal cladding shall be performed before the weld metal cladding is deposited. The magnetic particle or liquid penetrant examination of weld surfaces that are not accessible after a postweld heat treatment shall be performed prior to the operation which caused this inaccessibility. These examinations shall be performed before PWHT.

(e) Ultrasonic examination of electroslag welds in ferritic materials shall be performed after a grain refining heat treatment, when performed, or after final postweld heat treatment.

ND-5200 EXAMINATION OF WELDS

ND-5210 CATEGORY A VESSEL WELDED JOINTS IN VESSELS AND SIMILAR WELDED JOINTS IN PIPING, PUMPS, AND VALVES

ND-5211 Vessels

ND-5211.1 General Requirements

(a) Category A welded joints (ND-3351.1) shall be fully radiographed when:

(1) the thickness exceeds the limits of ND-5211.2 or ND-5211.3;

(2) the welds are based on a joint efficiency permitted by ND-3352.1(a);

(3) the butt welds in nozzles or communicating chambers are attached to vessel sections or heads which are required to be fully radiographed by (1) or (2) above;

(4) the welds are made by the electroslag welding process.

(b) Welds not required to be fully radiographed by (a) above shall be examined by spot radiography in accordance with the requirements of ND-5111, except as permitted by (c) below. Spot radiography is required when a joint efficiency described in ND-3352.1(b) is used.

**TABLE ND-5211.2-1
THICKNESS ABOVE WHICH FULL
RADIOGRAPHIC EXAMINATION OF BUTT
WELDED JOINT IS MANDATORY**

P-Number Classification of Material	Nominal Thickness Above Which Butt Welded Joints Shall Be Fully Radiographed, in.
1	1 1/4
3	3/4
4	5/8
5	0
7	5/8
8	1 1/2
10	5/8
11	5/8

TABLE ND-5211.2-1 THICKNESS ABOVE WHICH FULL RADIOGRAPHIC EXAMINATION OF BUTT WELDED JOINT IS MANDATORY

(c) No radiography is required when the vessel or part is designed for external pressure only or when the design complies with ND-3352.1(c).

ND-5211.2 Ferritic Materials.

Complete radiography shall be performed at each butt welded joint at which the thinner of the plate or vessel wall thickness at the welded joint exceeds the thickness limit above which full radiography is required in Table ND-5211.2-1.

ND-5211.3 Nonferrous Materials

(a) Vessels or parts of vessels constructed of nonferrous materials shall be radiographed in accordance with the requirements of ND-3352.

(b) Welded butt joints in vessels constructed of materials covered by specifications SB-163 (Alloy 800 only), SB-333, SB-334, SB-335, SB-336, SB-407, SB-408, SB-409, SB-443, SB-444, and SB-446 shall be examined radiographically for their full length when the thinner of the plate or vessel wall thicknesses at the welded joint exceeds $\frac{3}{8}$ in.

(c) Vessels constructed of unalloyed titanium shall have all welded joints of Categories A and B fully radiographed.

(d) All welds, both groove and fillet, in components constructed with materials SB-333, SB-334, SB-335, and SB-336 shall be examined for the detection of cracks by the liquid penetrant method.

(e) All welded joints in vessels constructed of unalloyed titanium shall be examined by the liquid penetrant method.

Page 267

(f) All welded joints in components or parts constructed with materials SB-163 (Alloy 800 only), SB-407, SB-408, SB-409, SB-443, SB-444, and SB-446 not required to be radiographed shall be examined by the liquid penetrant method.

ND-5212 Piping, Pumps, and Valves

Longitudinal welded joints in piping greater than NPS 2 (DN 50) shall be examined by the requirements of ND-2500. Longitudinal welded joints in pressure retaining parts of pumps and valves greater than NPS 2 (DN 50) shall be examined in accordance with the requirements of ND-2500 for the applicable product form. Butt welds made by the electroslag welding process shall be radiographed for their entire length.

ND-5220 CATEGORY B VESSEL WELDED JOINTS AND CIRCUMFERENTIAL WELDED JOINTS IN PIPING, PUMPS, AND VALVES

ND-5221 Vessels

(a) Category B welded joints (ND-3351.2) shall be fully radiographed when:

- (1) the thickness exceeds the limits of ND-5211.2 or ND-5211.3, except as permitted in (b) below;
- (2) the welds are based on a joint efficiency permitted by ND-3352.1(a), except as permitted in (b) below;
- (3) they are butt welds in nozzles or communicating chambers attached to vessel sections or heads that are required to be radiographed and exceed NPS 10 (254 mm) or $1\frac{1}{8}$ in. (29 mm) wall thickness;
- (4) the welds are made by the electroslag welding process.

(b) In accordance with (a)(2) above, any Category B and similar type welds not required to be fully radiographed by thickness or location as in (a) above shall as a minimum be partially radiographed. This shall consist of a radiographic examination at least 6 in. long of any section of the weld picked at random plus a similar examination of any intersection of the weld with all Category A and similar welds in either of the sections being connected. Acceptance standards for partially examined welds shall be as set forth in ND-5321.

(c) The welds not required to be radiographed by (a) or (b) above shall be examined by spot radiography except as permitted by (d) below. Spot radiography is required when a joint efficiency described in ND-3352.1(b) is used.

(d) No radiography is required when a vessel or part is designed for external pressure only or when a design complies with ND-3352.1(c).

(e) The requirements of ND-5211.2 and ND-5211.3 shall be met.

ND-5222 Piping, Pumps, and Valves

Circumferential welded joints in piping, pumps, and valves greater than NPS 2 (DN 50) shall be examined by either the magnetic particle, liquid penetrant, or radiographic methods. Acceptance standards shall be those stated in ND-5300.

ND-5230 CATEGORY C VESSEL WELDED JOINTS AND SIMILAR WELDED JOINTS IN PIPING, PUMPS, AND VALVES

ND-5231 Vessels

(a) Category C full penetration welds shall be fully radiographed when:

- (1) the thickness exceeds the requirements of ND-5211.2 or ND-5211.3;
 - (2) they are butt welds in nozzles or communicating chambers attached to vessel sections or heads that are required to be radiographed and exceed NPS 10 (254 mm) or $1\frac{1}{8}$ in. (29 mm) wall thickness;
 - (3) the welds are made by the electroslag process.
- (b) Any Category C butt weld not required to be fully radiographed by thickness or location using the joint efficiency of ND-3352.1(a) shall meet the requirements of ND-5221(b).
- (c) The welds not required to be fully radiographed by (a) above shall be examined by spot radiography, except as permitted by (d) below. Spot radiography is required when the butt welds are designed with a joint efficiency as described in ND-3352.1(b).
- (d) No radiography is required when the vessel or part is designed for external pressure only, when the design complies with ND-3352.1(c), or when the joint is not a butt welded joint.

ND-5232 Piping, Pumps, and Valves

The requirements for welded joints similar to Category C shall be the same as given in ND-5222.

Page 268

ND-5240 CATEGORY D VESSEL WELDED JOINTS AND SIMILAR JOINTS IN PIPING, PUMPS, AND VALVES

ND-5241 Vessels

- (a) Full penetration butt welds of Category D (ND-3351.4) shall be fully radiographed when located:
- (1) in a vessel or part that is designed with a joint efficiency as permitted by ND-3352.1(a);
 - (2) in nozzles or communicating chambers that are attached to vessel sections or heads required to be fully radiographed.
- (b) Butt welds not required to be fully radiographed by (a) above shall be examined by spot radiography, except as permitted by (c) below.
- (c) No radiography is required for butt welded joints when the vessel or part is designed for external pressure only or when the design complies with ND-3352.1(c). Radiography is not required for nonbutt-welded joints.

ND-5242 Piping, Pumps, and Valves

The requirements for welded joints similar to Category D welded joints shall be as given in ND-5222.

ND-5260 WELDED STAYED CONSTRUCTION

Welded staybolts need not be radiographed. When welded stays are used to stay jacketed vessels, the inside weld shall be visually examined before closing plates are attached.

ND-5270 SPECIAL WELDS

ND-5272 Weld Metal Cladding

Weld metal cladding shall be examined by the liquid penetrant method.

ND-5273 Hard Surfacing

Hard surfacing shall be examined by the liquid penetrant method in accordance with ND-2546, and the acceptance standards applicable to material less than $\frac{5}{8}$ in. thick shall apply. Penetrant examination is not required for hard surfacing on valves with inlet connections NPS 4 or less.

ND-5274 Tube-to-Tubesheet Welds

Tube-to-tubesheet welds shall be examined by the liquid penetrant method.

ND-5275 Brazed Joints

Flux and flux residue shall be removed from all surfaces prior to examination. Joints shall be visually examined on all accessible surfaces to determine whether there has been adequate flow of brazing metal through the joint. Optical aids may be employed for indirect visual examination of joints which cannot be directly examined.

ND-5276 Inertia and Continuous Drive Friction Welds

When radiographic examination is required by this Article, inertia and continuous drive friction welds shall also be examined by the ultrasonic method to verify bonding over the entire area.

ND-5278 Electroslag Welds

In addition to the requirements for the type of weld being examined, all complete penetration welds made by the electroslag welding process in ferritic materials shall be ultrasonically examined.

ND-5279 Special Exceptions

When the joint detail does not permit radiographic examination of joints attaching penetration assemblies, which are fabricated as appurtenances, or the closing seam within an electrical penetration assembly which is not fabricated as an appurtenance, ultrasonic examination plus liquid penetrant or magnetic particle examination of the completed weld may be substituted for the radiographic examination. The absence of suitable radiographic equipment shall not be justification for such substitution. The substitution of ultrasonic examination can be made, provided the examination is performed using a detailed written procedure which has been proven by actual demonstration to the satisfaction of the Inspector as capable of detecting and locating defects described in this Subsection. The nondestructive examination shall be in accordance with Section V and meet the acceptance standards of ND-5300.

Page 269

ND-5280 WELDED JOINTS IN STORAGE TANKS

ND-5282 Atmospheric Storage Tanks

ND-5282.1 Sidewall Joints.

Sidewall joints shall be examined in accordance with ND-5211 and ND-5221.

ND-5282.2 Roof Joints and Roof-to-Sidewall Joints.

Roof joints and roof-to-sidewall joints shall be examined visually.

ND-5282.3 Bottom Joints.

Bottom joints shall be examined from the inside of the tank by applying soapsuds to the joints and pulling a partial vacuum of at least 3 psi by means of a vacuum box with transparent top.

ND-5282.4 Bottom-to-Sidewall Joints.

Bottom-to-sidewall joints shall be examined by the vacuum box method as required by ND-5282.3. Alternatively, MT or PT examination may be substituted for the vacuum box tests, provided the outside of the joint is accessible for visual examination during the test required by ND-6000.

ND-5282.5 Nozzle-to-Tank Joints.

Nozzle-to-sidewall or bottom joints shall be examined by either the magnetic particle or liquid penetrant method. Nozzle-to-roof joints shall be visually examined.

ND-5282.6 Joints in Nozzles.

All joints in roof nozzles shall be visually examined. Joints in other nozzles shall be examined by the liquid penetrant or magnetic particle method.

ND-5282.7 Other Joints.

Joints not specifically covered by ND-5282 shall be examined in the same manner as similar weld joints in vessels as required by this Subarticle.

ND-5283 Welds in 0-15 psi (0-103 kPa) Storage Tanks

ND-5283.1 Sidewall Joints.

Sidewall joints shall be examined in accordance with ND-5211 and ND-5221.

ND-5283.2 Roof Joints.

Roof joints shall be examined in accordance with ND-5211.

ND-5283.3 Roof-to-Sidewall Joints.

Roof-to-sidewall joints shall be radiographed in accordance with ND-5211 if the design permits. If not radiographed, this joint shall be examined by the magnetic particle or liquid penetrant method.

ND-5283.4 Bottom Joints.

Joints in bottoms supported directly on grade shall be examined by the vacuum box method as detailed in ND-5282.3. Joints not supported directly on grade shall be fully radiographed.

ND-5283.5 Bottom-to-Sidewall Joints.

Bottom-to-sidewall joints shall be examined by the vacuum box method as required by ND-5282.3. Alternatively, MT or PT examination may be substituted for the vacuum box test, provided the outside of the joint is accessible for visual examination during the test required by ND-6000.

ND-5283.6 Nozzle-to-Tank Joints.

Nozzle-to-tank joints shall be examined by either the magnetic particle or the liquid penetrant method.

ND-5283.7 Joints in Nozzles.

Joints in nozzles shall be examined by either the magnetic particle or the liquid penetrant method.

ND-5283.8 Other Joints.

Joints not specifically covered by ND-5283 shall be examined in the same manner as similar weld joints in vessels as required by this Subarticle.

ND-5300 ACCEPTANCE STANDARDS

ND-5320 RADIOGRAPHIC ACCEPTANCE STANDARDS

ND-5321 Evaluation of Indications

Indications shown on the radiographs of welds and characterized as imperfections are unacceptable under the following

conditions:

(a) any indication characterized as a crack or zone of incomplete fusion or penetration;

(b) any other elongated indication which has a length greater than:

(1) $\frac{1}{4}$ in. for t up to $\frac{3}{4}$ in., inclusive

(2) $\frac{1}{3}t$ for t from $\frac{3}{4}$ in. to $2\frac{1}{4}$ in., inclusive

(3) $\frac{3}{4}$ in. for t over $2\frac{1}{4}$ in.

where t is the thickness of the thinner portion of the weld;

(c) internal root weld conditions are acceptable when the density change as indicated in the radiograph is not abrupt; elongated indications on the radiograph at either edge of such conditions shall be unacceptable as provided in (b) above;

(d) any group of aligned indications having an aggregate length greater than t in a length of $12t$ unless the minimum distance between successive indications exceeds $6L$, in which case the aggregate length is unlimited, L being the length of the largest indication;

(e) rounded indications in excess of that shown as acceptable in Appendix VI;

Page 270

(f) when a Category B or C butt weld, partially radiographed as required in ND-5221(b) or ND-5231(b), is acceptable in accordance with (a) through (e) above, the entire weld length represented by this partial radiograph is acceptable;

(g) when a Category B or C butt weld, partially radiographed as required in ND-5221(b) or ND-5231(b), has been examined and any radiograph discloses welding which does not comply with the minimum quality requirements of (a) through (e) above, one additional section at least 6 in. long for each radiograph disclosing such defective welding, but a minimum total of two, shall be radiographically examined in the same weld unit at other locations. The location of these additional radiographs shall be acceptable to the Inspector.

(1) If the additional sections examined show welding which meets the minimum quality requirements of (a) through (e) above, the entire weld unit represented by the total number of radiographs is acceptable. The defective welding disclosed by the partial radiographs shall be removed and the area repaired by welding. The weld repaired areas shall be radiographically examined.

(2) If any of the additional sections examined shows welding which does not comply with the minimum quality requirements of (a) through (e) above, the entire unit of weld represented shall be rejected. The entire rejected weld represented shall be rewelded, or the entire unit of weld represented shall be completely radiographed and any part of the weld not meeting the requirements of (a) through (e) above shall be repaired and reexamined radiographically. The rewelded joint shall be partially radiographed as required in ND-5221(b) or ND-5231(b), or the weld repaired areas shall be radiographically reexamined.

ND-5322 Evaluation of Indications (Spot Radiography)

The acceptability of welds examined by spot radiography shall be determined by (a), (b), and (c) below.

(a) Welds in which the radiograph shows any type of crack or zone of incomplete fusion or penetration shall be unacceptable.

(b) Welds in which the radiographs show slag inclusions or cavities shall be unacceptable if the length of any such imperfection is greater than $\frac{2}{3}T$ where T is the thickness of the thinner plate welded. If several imperfections within the above limitations exist in line, the welds shall be judged acceptable if the sum of the longest dimensions of all such imperfections is not more than T in a length of $6T$ or proportionately for radiographs shorter than $6T$ and if the longest imperfections considered are separated by at least $3L$ of acceptable weld metal, where L is the length of the longest imperfection. The maximum length of acceptable imperfections shall be $\frac{3}{4}$ in. Any such imperfections shorter than $\frac{1}{4}$ in. shall be acceptable for any plate thickness.

(c) Rounded indications are not a factor in the acceptability of welds not required to be fully radiographed.

(d) Evaluation and Retests

(1) When an area which is spot radiographed is acceptable in accordance with (a) and (b) above, the entire weld length represented by this radiograph is acceptable.

(2) When a spot has been examined and the radiograph discloses welding which does not comply with the minimum quality requirements of (a) and (b) above, two additional spots shall be radiographically examined in the same weld unit at locations away from the original spot. The locations of these additional spots shall be determined by the Inspector or fabricator as provided for the original spot examination in ND-5420(c).

(a) If the two additional spots examined show welding which meets the minimum quality requirements of (a) and (b) above, the entire weld unit represented by the three radiographs is acceptable. The defective welding disclosed by the first of the three radiographs may be removed and the area repaired by welding, or it may be allowed to remain in the weld joint, at the discretion of the Inspector.

(b) If either of the two additional spots examined shows welding which does not comply with the minimum quality requirements of (a) and (b) above, the entire unit of weld represented shall be rejected. The entire rejected weld shall be removed and the joint shall be rewelded or, at the fabricator's option, the entire unit of weld represented shall be completely radiographed and defective welding only need be corrected.

(c) Repair welding shall be performed using a qualified procedure and in a manner acceptable to the Inspector. The rewelded joint or the weld repaired areas shall be spot radiographically examined at one location in accordance with the foregoing requirements of ND-5420.

ND-5330 ULTRASONIC ACCEPTANCE STANDARDS

All imperfections which produce a response greater than 20% of the reference level shall be investigated to the extent that the operator can determine the shape, identity, and location of all such imperfections and

Page 271

evaluate them in terms of the acceptance standards as follows.

(a) Imperfections are unacceptable if the indications exceed the reference level amplitude and have lengths exceeding:

(1) $\frac{1}{4}$ in. (6 mm) for t up to $\frac{3}{4}$ in. (19 mm), inclusive

(2) $\frac{1}{3}t$ for t from $\frac{3}{4}$ in. (19 mm) to $2\frac{1}{4}$ in. (57 mm), inclusive

(3) $\frac{3}{4}$ in. (19 mm) for t over $2\frac{1}{4}$ in. (57 mm) where t is the thickness of the weld being examined; if a weld joins two members having different thicknesses at the weld, t is the thinner of these two thicknesses.

(b) Indications characterized as cracks, lack of fusion, or incomplete penetration are unacceptable, regardless of length.

ND-5340 MAGNETIC PARTICLE ACCEPTANCE STANDARDS

ND-5341 Evaluation of Indications

(a) Mechanical discontinuities at the surface are revealed by the retention of the examination medium. All indications are not necessarily defects, however, since certain metallurgical discontinuities and magnetic permeability variations may produce similar indications which are not relevant.

(b) Any indication which is believed to be nonrelevant shall be reexamined by the same or other nondestructive examination methods to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. After an indication has been verified to be nonrelevant, it is not necessary to reinvestigate repetitive nonrelevant indications of the same type. Nonrelevant indications which would mask defects are unacceptable.

(c) Relevant indications are indications which result from imperfections. Linear indications are indications in which the length is more than three times the width. Rounded indications are indications which are circular or elliptical with the length equal to or less than three times the width.

ND-5342 Acceptance Standards

(a) Only imperfections producing indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Imperfections producing the following indications are unacceptable:

- (1) any cracks or linear indications;
- (2) rounded indications with dimensions greater than $\frac{3}{16}$ in. (4.8 mm);
- (3) four or more rounded indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;
- (4) ten or more rounded indications in any 6 sq in. (3871 mm²) of surface with the major dimension of this area not to exceed 6 in. (152 mm) with the area taken in the most unfavorable location relative to the indications being evaluated.

ND-5350 LIQUID PENETRANT ACCEPTANCE STANDARDS

ND-5351 Evaluation of Indications

(a) Mechanical discontinuities at the surface are revealed by bleeding out of the penetrant; however, localized surface discontinuities such as may occur from machining marks, surface conditions, or an incomplete bond between base metal and cladding may produce similar indications which are nonrelevant.

(b) Any indication which is believed to be nonrelevant shall be reexamined to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. Nonrelevant indications and broad areas of pigmentation which would mask defects are unacceptable.

(c) Relevant indications are indications which result from imperfections. Linear indications are indications in which the length is more than three times the width. Rounded indications are indications which are circular or elliptical with the length equal to or less than three times the width.

ND-5352 Acceptance Standards

(a) Only imperfections producing indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Imperfections producing the following indications are unacceptable:

- (1) any cracks or linear indications;
- (2) rounded indications with dimensions greater than $\frac{3}{16}$ in.;
- (3) four or more rounded indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;
- (4) ten or more rounded indications in any 6 sq in. (3871 mm²) of surface with the major dimension of this area not to exceed 6 in. (152 mm) with the area taken in the most unfavorable location relative to the indications being evaluated.

Page 272

ND-5360 VISUAL ACCEPTANCE STANDARDS FOR BRAZED JOINTS

Brazing metal shall give evidence of having flowed uniformly through a joint by the appearance of an uninterrupted, narrow, visible line of brazing alloy at the joint.

ND-5380 GAS AND BUBBLE FORMATION TESTING

For gas and bubble formation testing, the test procedure shall be in accordance with Section V, Article 10, T-1030. When vacuum box testing is used, the soak time shall be a minimum of 10 sec. Any indication of leaking, by the formation of bubbles or the breaking of the continuous soap film by leaks, shall be evidence of an unacceptable condition.

ND-5400 SPOT EXAMINATION OF WELDED JOINTS²

ND-5410 GENERAL REQUIREMENTS

Vessels and tanks that have butt welded joints that are not radiographed for their full length and which are required to be spot examined by the rules of this Subsection shall be examined locally by spot radiography in accordance with this Subarticle, except for those vessels or tanks designed for external pressure only.

2 (a) Spot radiographing of a welded joint is recognized as an effective inspection tool. The spot radiography rules are also considered to be an aid to quality control. Spot radiographs made directly after a welder or an operator has completed a unit of weld proves that the work is or is not being done in accordance with a satisfactory procedure. If the work is unsatisfactory, corrective steps can then be taken to improve the welding in the subsequent units, which unquestionably will improve the weld quality.

(b) Spot radiography in accordance with these rules will not insure a fabrication product of predetermined quality level throughout. It must be realized that an accepted vessel or tank under these spot radiography rules may still contain defects which might be disclosed on further examination. If all radiographically disclosed unacceptable weld defects are required to be eliminated from a vessel or tank, then 100% radiography shall be employed.

ND-5420 MINIMUM EXTENT OF SPOT RADIOGRAPHIC EXAMINATION

(a) One spot shall be examined in the first 50 ft of welding in each vessel and one spot shall be examined for each additional 50 ft (15.2 m) of welding or fraction thereof, except that when identical vessels or tanks individually of less than 50 ft (15.2 m) seam length are being fabricated under the rules of this Subsection, 50 ft (15.2 m) increments of welding may be represented by one spot examination.

(b) Such additional spots as may be required shall be selected so that an examination is made of the welding of each welding operator or welder. Under conditions where two or more welders or welding operators make weld layers in a joint or on the two sides of a double welded butt joint, one spot examination may represent the work of both welders or welding operators.

(c) Each spot examination shall be made as soon as practicable after the completion of the increment of weld that is to be examined. The location of the spot shall be chosen by the Inspector, except that when the Inspector has been duly notified in advance and cannot be present or otherwise make the selection, the Certificate Holder may exercise his own judgment in selecting the spots.

ND-5430 STANDARDS FOR SPOT RADIOGRAPHIC EXAMINATION

Spot examination by radiography shall be made in accordance with the technique prescribed in Section V, Article 2. The minimum length of spot radiograph shall be 6 in. (152 mm).

[98]

ND-5440 EVALUATION AND RETESTS

(a) When an area which is spot radiographed is acceptable in accordance with ND-5322(a) and (b), the entire weld length represented by this radiograph is acceptable.

(b) When an area which is spot radiographed has been examined and the radiograph discloses welding which does not comply with the minimum quality requirements of ND-5322(a) and (b), two additional spots shall be radiographically examined in the same weld unit at locations away from the original spot. The locations of these additional spots shall be determined by the Inspector or Certificate Holder as provided for the original spot examination in ND-5420(c).

(1) If the two additional spots examined show welding which meets the minimum quality requirements of ND-5322(a) and (b), the entire weld unit represented by the three radiographs is acceptable. The defective welding disclosed by the first of the three radiographs may be removed and the area repaired by welding, or it may be allowed to remain in the weld joint, at the discretion of the Inspector.

Page 273

(2) If either of the two additional spots examined shows welding which does not comply with the minimum quality requirements of ND-5322(a) and (b), the entire unit of weld represented shall be rejected. The entire rejected weld shall be removed and the joint shall be rewelded, or, at the Certificate Holder's option, the entire unit of weld represented shall be

completely radiographed and defective welding only need be corrected.

(3) Repair welding shall be performed using a qualified procedure and in a manner acceptable to the Inspector. The rewelded joint or the weld repaired areas shall be spot radiographically examined at one location in accordance with the foregoing requirements of ND-5400.

[98]

ND-5500 QUALIFICATIONS AND CERTIFICATION OF NONDESTRUCTIVE EXAMINATION PERSONNEL

ND-5510 GENERAL REQUIREMENTS

Organizations performing Code required nondestructive examinations shall use personnel competent and knowledgeable to the degree specified by ND-5520. When these services are subcontracted by the Certificate Holder or Quality System Certificate Holder, he shall verify the qualification of personnel to the requirements of ND-5520. All nondestructive examinations required by this Subsection shall be performed by and the results evaluated by qualified nondestructive examination personnel.

ND-5520 PERSONNEL QUALIFICATION, CERTIFICATION, AND VERIFICATION

ND-5521 Qualification Procedure

(a) Personnel performing nondestructive examinations shall be qualified in accordance with the recommended guidelines of SNT-TC-1A³⁴ The Employer's⁵ written practice required by paragraph 5 of SNT-TC-1A shall identify his requirements relative to the recommended guidelines. The recommended guidelines of SNT-TC-1A shall be considered minimum requirements, except as modified in (1) through (5) below:

(1) Qualification of Level III nondestructive examination personnel shall be by examination.

(a) The basic and method examinations, paragraphs 8.8(1) and 8.8(2) of SNT-TC-1A, may be prepared and administered by the Employer, ASNT, or an outside agency.

(b) The specific examination, paragraph 8.8(3) of SNT-TC-1A, shall be prepared and administered by the Employer or an outside agency. The Employer or outside agency administering the specific examination shall identify the minimum grade requirement in the written program when the basic and method examinations have been administered by ASNT, which issues grades on a pass/fail basis. In this case, the minimum grade for the specific examination may not be less than 80%.

(2) The written practice identified in paragraph 5 of SNT-TC-1A and the procedures used for examination of personnel shall be referenced in the Employer's Quality Program.

(3) The number of hours of training and experience for nondestructive examination personnel who perform only one operation of a nondestructive examination method that consists of more than one operation, or perform nondestructive examination of limited scope, may be less than that recommended in Table 6.3.1 of SNT-TC-1A. The training and experience times shall be described in the written practice, and any limitations or restrictions placed on the certification shall be described in the written practice and on the certificate.

The minimum classroom training times identified in Table 6.3.1 of SNT-TC-1A may be reduced from 8 and 16 hr to 4 and 8 hr, respectively, for visual examination personnel.

3 SNT-TC-1A is a Recommended Practice for Nondestructive Testing Personnel Qualification and Certification published by the American Society for Nondestructive Testing, 1711 Arlingate Lane, P.O. Box 28518, Columbus, OH 43228-0518. SNT-TC-1A-1992 is the applicable edition.

4 Personnel qualified by examination and certified to previous editions of SNT-TC-1A are considered to be qualified to the 1992 edition when the recertification is based on continuing satisfactory performance. All reexaminations and new examinations shall be in accordance with the 1992 edition.

5 Employer, as used in this Article, shall include: N Certificate Holders; Quality System Certificate Holders; and Material Organizations that are qualified in accordance with NCA-3862(a)(1); and organizations that provide subcontracted nondestructive examination services to organizations described above.

(4) For visual examination, the Jaeger Number 1 letters shall be used in lieu of the Jaeger Number 2 letters specified in paragraph 8.2(1) of SNT-TC-1A. The use of equivalent type and size letters is permitted.

(5) A Level I individual shall be qualified to perform specific setups, calibrations, and tests, and to record and evaluate data by comparison with specific acceptance criteria defined in written instructions. The Level I individual shall implement these written NDE instructions under the guidance of a Level II or III individual. A Level I individual may independently accept the results of nondestructive examinations when the specific acceptance criteria are defined in the written instructions.

(b) For nondestructive examination methods not covered by SNT-TC-1A documents, personnel shall be qualified to comparable levels of competency by subjection to comparable examinations on the particular method involved.

(c) The emphasis shall be on the individual's ability to perform the nondestructive examination in accordance with the applicable procedure for the intended application.

(d) For nondestructive examination methods that consist of more than one operation or type, it is permissible to use personnel qualified to perform one or more operations. As an example, one person may be used who is qualified to conduct radiographic examination and another may be used who is qualified to interpret and evaluate the radiographic film.

ND-5522 Certification of Personnel

(a) The Employer retains responsibility for the adequacy of the program and is responsible for certification of Levels I, II, and III nondestructive examination personnel.

(b) When ASNT is the outside agency administering the Level III basic and method examinations [ND-5521(a)(2)], the Employer may use a letter from ASNT as evidence on which to base the certification.

(c) When an outside agency is the examining agent for Level III qualification of the Employer's personnel, the examination results shall be included with the Employer's record.

ND-5523 Verification of Nondestructive Examination Personnel Certification

The Certificate Holder has the responsibility to verify the qualification and certification of nondestructive examination personnel employed by Material Organizations qualified by them in accordance with NCA-3820 and subcontractors who provide nondestructive examination services to them.

ND-5530 RECORDS

Personnel qualification records identified in paragraph 9.4 of SNT-TC-1A shall be retained by the Employer.

ND-5700 EXAMINATION REQUIREMENTS FOR EXPANSION JOINTS

ND-5720 BELLOWS EXPANSION JOINTS

The examinations stipulated in (a) through (f) below are required to verify the integrity of bellows expansion joints for installation in piping systems.

(a) The formed bellows shall be determined by visual examination to be free of defects such as notches, crevices, material buildup or upsetting, or weld spatter, which may serve as points of local stress concentration. Suspect surface areas shall be further examined by liquid penetrant method.

(b) The longitudinal seam weld in the bellows shall be examined by the liquid penetrant method. When the individual ply thickness exceeds $\frac{1}{8}$ in. (3.2 mm), the weld shall also be radiographed. These examinations may be performed either before or after the bellows is formed.

(c) The circumferential attachment weld between the bellows and pipe or flange shall be examined by the liquid penetrant method when the total bellows thickness is $\frac{1}{4}$ in. (6 mm) or less. When the total thickness exceeds this limit, the weld shall be radiographed, except where radiography is not meaningful; for example, when the weld thickness constitutes less than

20% of the total thickness being radiographed, liquid penetrant examination may be substituted.

(d) In the case of liquid penetrant examination of bellows welds, imperfections producing the following indications are unacceptable:

- (1) cracks or linear indications;
- (2) four or more rounded indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;
- (3) five or more randomly distributed rounded indications in a weld length of 6 in. (152 mm);
- (4) any rounded indication exceeding the lesser of one-half the bellows thickness or $\frac{1}{16}$ in. (1.6 mm) in diameter.

(e) The examination of all other welds in the expansion joint shall comply with this Article.

Page 275

(f) The variation of the cylindrical end thickness of the formed bellows from the nominal or specified thickness shall not exceed the values given in Table 2 of SA-480. Thinning of the bellows material during forming shall be considered in the design and selection of material thickness but need not be limited to the values specified in Table 2 of SA-480.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 ND-6000

ARTICLE ND-6000 TESTING

Page 277

ND-6100 GENERAL REQUIREMENTS

ND-6110 PRESSURE TESTING OF COMPONENTS, APPURTENANCES, AND SYSTEMS

ND-6111 Scope of Pressure Testing

All pressure retaining components, appurtenances, and completed systems shall be pressure tested, except as specified in (a) through (d) below. Portions of piping systems which are exempt shall be identified in the Design Specification and N-5 Data Report Form. The design specification shall be available to the Authorized Nuclear Inspector when the balance of the system is hydrostatically tested.

(a) Bolts, studs, nuts, washers, and gaskets are exempt.

(b) The following portions of piping systems whose only function is to transport fluids to and from spray ponds, lakes, reservoirs, or tanks which are open to the atmosphere are exempt:

(1) piping downstream of the last isolation valve preceding the pipe discharge to the spray pond, lake, reservoir or tank; and

(2) piping upstream of the intake pump inlet isolation valve.

(c) Where systems discharge into Class 3 vessels or the gaseous regions of MC containment vessels through spargers or spray nozzles, only that portion of the system external to the vessel is required to be pressure tested.

(d) The portion of a Class 3 safety and safety relief valve discharge piping that is submerged below the minimum Design Level in a containment pressure suppression pool of a MC or CC containment vessel is exempt. The minimum Design Level shall be specifically designated in the Design Specification.

ND-6112 Pneumatic Testing

A pneumatic test in accordance with ND-6300 may be substituted for the hydrostatic test when permitted by ND-6112.1

(a).

ND-6112.1 Pneumatic Test Limitations

(a) A pneumatic test may be used in lieu of a hydrostatic test only when any of the following conditions exist:

(1) when components, appurtenances, or systems are so designed or supported that they cannot safely be filled with liquid;¹

(2) when components, appurtenances, or systems which are not readily dried, are to be used in services where traces of the testing medium cannot be tolerated.

(b) A pneumatic test at a pressure not to exceed 25% of the Design Pressure may be applied, prior to either a hydrostatic or a pneumatic test, as a means of locating leaks.

ND-6112.2 Precautions to Be Employed in Pneumatic Testing.

Compressed gaseous fluid is hazardous when used as a testing medium. Therefore, it is recommended that special precautions for protection of personnel be taken when a gaseous fluid under pressure is used as a test medium.

ND-6113 Witnessing of Pressure Tests

Pressure testing required by this Article shall be performed in the presence of the Inspector, except that testing of each line valve and each pump having piping connections of NPS 4 (DN 100) and less need not be witnessed by the Inspector. For line valves and pumps NPS 4 and less, the Inspector's review and acceptance of the Certificate Holder's test records will be authorization to sign the Data Report Form, and takes precedence over NCA-5280.

ND-6114 Time of Pressure Testing

ND-6114.1 System Pressure Test.

The installed system shall be pressure tested prior to initial operation.

¹ These tests may be made with the item being tested partially filled with liquid, if desired.

The pressure test may be performed progressively on erected portions of the system.

ND-6114.2 Component and Appurtenance Pressure Test

(a) Components and appurtenances shall be pressure tested prior to installation in a system, except as permitted in (b) below.

(b) The system pressure test may be substituted for a component or appurtenance pressure test, provided:

(1) the component can be repaired by welding in accordance with the rules of ND-4130 and ND-4450, if required, as a result of the system pressure test;

(2) the component repair weld can be postweld heat treated in accordance with ND-4620, if required, and nondestructively examined in accordance with rules of ND-4130 and ND-4450, as applicable; and

(3) the component is resubjected to the required system pressure test following the completion of repair and examination if the repair is required to be radiographed by ND-4453.4.

(c) Valves require pressure testing prior to installation in a system in accordance with ND-3500.

(d) Items which, when assembled, form a completed pump or valve may be tested in the form of subassemblies, provided:

(1) the test pressure is in accordance with the requirements of ND-6221;

(2)

- (2) the pressure test is performed in a manner which, in the subassembly under test, will simulate the loadings present when the completed pump or valve is assembled and pressurized;
- (3) the component Certificate Holder approves any pressure test of component subassemblies;
- (4) the component Certificate Holder specifies the pressure test requirements and test pressure to be used;
- (5) each subassembly pressure test is performed by a Certificate Holder and is performed in the presence of the Authorized Nuclear Inspector;
- (6) each subassembly pressure tested by other than the component Certificate Holder is stamped with the NPT symbol except as provided in NCA-8330; the test pressure shall be identified on the Partial Data Report Form;
- (7) each subassembly pressure tested by other than the component Certificate Holder is listed on the Code Data Report Form;
- (8) the pressure tested subassemblies of pumps or valves are subsequently assembled by mechanical methods only;
- (9) welds examined during the subassembly pressure test need not be reexamined during the system pressure test.

ND-6114.3 Material Pressure Test.

The component or appurtenance pressure test may be used in lieu of any such test required by the material specification for a part or material used in the component or appurtenance, provided:

- (a) nondestructive examinations, if required by the material specification, can be performed subsequent to the component or appurtenance pressure test;
- (b) the material can be repaired by welding in accordance with rules of ND-4130 if required as a result of the pressure test; and
- (c) postweld heat treatment, when required after repairs, can be performed in accordance with ND-4620.

ND-6115 Machining After Pressure Test

An additional amount of material, not to exceed 10% of the wall thickness or $\frac{3}{8}$ in. (10 mm), whichever is less, is permitted on the completed component during pressure testing, where machining to critical dimensions and tolerances is required.

ND-6120 PREPARATION FOR TESTING

ND-6121 Exposure of Joints

All joints, including welded joints, shall be left uninsulated and exposed for examination during the test.

ND-6122 Addition of Temporary Supports

Components designed to contain vapor or gas may be provided with additional temporary supports, if necessary, to support the weight of the test liquid.

ND-6123 Restraint or Isolation of Expansion Joints

Expansion joints shall be provided with temporary restraints, if required, for the additional pressure load under test.

ND-6124 Isolation of Equipment Not Subjected to Pressure Test

Equipment that is not to be subjected to the pressure test shall be either disconnected from the component or system or isolated during the test by a blind flange or similar means. Valves may be used if the valves with their closures are suitable for proposed test pressure.

ND-6125 Treatment of Flanged Joints Containing Blanks

Flanged joints at which blanks are inserted to isolate other equipment during the test need not be retested.

ND-6126 Precautions Against Test Medium Expansion

If a pressure test is to be maintained for a period of time and the test medium in the system is subject to thermal expansion, precautions shall be taken to avoid excessive pressure.

ND-6127 Check of Test Equipment Before Applying Pressure

The test equipment shall be examined before pressure is applied to ensure that it is tight and that all low pressure filling lines and other items that should not be subjected to the test have been disconnected or isolated.

ND-6200 HYDROSTATIC TESTS

The requirements of this paragraph apply to all components except tanks, for which ND-6500 applies.

ND-6210 HYDROSTATIC TEST PROCEDURE

ND-6211 Venting During Fill Operation

The component or system in which the test is to be conducted shall be vented during the filling operation to minimize air pocketing.

ND-6212 Test Medium and Test Temperature

(a) Water or an alternative liquid, as permitted by the Design Specification, shall be used for the hydrostatic test.

(b) It is recommended that the test be made at a temperature that will minimize the possibility of brittle fracture. The test pressure shall not be applied until the component, appurtenance or system, and the pressurizing fluid are at approximately the same temperature.

ND-6220 HYDROSTATIC TEST PRESSURE REQUIREMENTS

ND-6221 Minimum Hydrostatic Test Pressure

(a) The installed system shall be hydrostatically tested at not less than 1.25 times the lowest Design Pressure of any component within the boundary protected by the overpressure protection devices which satisfy the requirements of ND-7000.

(b) Valves shall be hydrostatically tested in accordance with the rules of ND-3500.

(c) Other components, excluding piping systems, shall be hydrostatically tested at not less than 1.50 times their Design Pressure.

(d) As an alternative to ND-6221(a) above, piping between the discharge side of a centrifugal pump and the first shutoff valve may be hydrostatically tested at the shutoff head of the pump. The pressure shall be maintained for a sufficient time to permit examination of all joints, connections, and regions of high stress.

ND-6222 Maximum Permissible Pressure

(a) If the minimum test pressure of ND-6221(a) or (d) is to be exceeded by 6% at any location, the upper limit shall be established by analysis using all loadings that may exist during the test.

(b) When testing a system, the test pressure shall not exceed the maximum permissible test pressure of any component in the system.

ND-6223 Hydrostatic Test Pressure Holding Time

The hydrostatic test pressure shall be maintained a minimum of 10 min prior to initiation of the examination for leakage required by ND-6224.

ND-6224 Examination for Leakage After Application of Pressure

Following the application of the hydrostatic test pressure for the required time (ND-6223), all joints, connections, and regions of high stress such as regions around openings and thickness transition sections shall be examined for leakage. Except in the case of pumps and valves, which shall be examined while at test pressure, this examination shall be made at a pressure equal to the greater of the Design Pressure or three-fourths of the test pressure, and it shall be witnessed by the Inspector. Leakage of temporary gaskets and seals, installed for the purpose of conducting the hydrostatic test, and which will be replaced later, may be

Page 284

permitted unless the leakage exceeds the capacity to maintain system test pressure for the required amount of time. Other leaks, such as from permanent seals, seats, and gasketed joints in components, may be permitted when specifically allowed by the Design Specifications. Leakage from temporary seals or leakage permitted by the Design Specification shall be directed away from the surface of the component to avoid masking leaks from other joints.

ND-6230 BELLOWS EXPANSION JOINTS

The hydrostatic test requirements for bellows expansion joints shall be as required in (a) through (c) below.

(a) The completed expansion joint shall be subjected to a hydrostatic test in accordance with the applicable provisions of this Article as supplemented by the Design Specifications.

(b) This test may be performed with the bellows fixed in the straight position, at its neutral length, when the design has been shown to comply with ND-3649.4(e)(1) or (e)(2). If the design is to comply with ND-3649(e)(3), this test shall be performed with the bellows fixed at the maximum design rotation angle or offset movement.

(c) In addition to inspecting the expansion joint for leaks and general structural integrity during the test, the Inspector shall also visually inspect the bellows for evidence of meridional yielding as defined in ND-3649.4(b) and for evidence of squirm as defined in ND-3649.4(c). If the design is to comply with ND-3649.4(e)(3), actual measurements shall be made before, during, and after the pressure test in accordance with ND-3649.4(b) and (c).

ND-6240 PROVISION FOR EMBEDDED OR INACCESSIBLE WELDED JOINTS IN PIPING

When welded joints in piping subassemblies or piping systems will be embedded or otherwise inaccessible for inspection at the time of the system hydrostatic test, either of the following alternatives may be employed. Alternative (b) does not apply to brazed joints.

(a) The piping subassembly, or portion of the piping system which is to be embedded, or will otherwise be inaccessible, shall be hydrostatically tested at some point in the fabrication or installation prior to embedment or inaccessibility.

(b) Radiography shall be performed on all circumferential butt welds, and either magnetic particle or liquid penetrant examination shall be performed on all fillet or socket welds in accordance with the requirements of ND-5000. The longitudinal butt welds shall meet the requirements of ND-2000. The hydrostatic test may then be performed after embedment using maintenance of pressure as the acceptance criterion for those welds only. The system shall be pressurized to the hydrostatic test pressure and then isolated from the pressurizing source for a period of 1 hr/in. of wall thickness but not less than 1 hr. During the test period, there shall be no drop in pressure.²

ND-6300 PNEUMATIC TESTS

ND-6310 PNEUMATIC TESTING PROCEDURES

ND-6311 General Requirements

When a pneumatic test is performed, it shall be conducted in accordance with the requirements of ND-6100 and this Subarticle.

ND-6312 Test Medium and Test Temperature

- (a) The gas used as the test medium shall be non flammable.
- (b) Testing temperature shall be in accordance with ND-6212(b).

ND-6313 Procedure for Applying Pressure

The pressure in the system shall gradually be increased to not more than one-half of the test pressure, after which the pressure shall be increased in steps of approximately one-tenth of the test pressure until the required test pressure has been reached.

ND-6320 PNEUMATIC TEST PRESSURE REQUIREMENTS

ND-6321 Minimum Required Pneumatic Test Pressure

- (a) The installed system shall be pneumatically tested at not less than 1.25 times the lowest Design Pressure of any component within the boundary protected by the overpressure protection devices which satisfy the requirements of ND-7000.

2 Temperature fluctuations within the piping system may affect the pressure. Precautions must be taken to ensure that the test is not biased by temperature effects.

Page 285

- (b) Valves shall be pneumatically tested in accordance with the rules of ND-3500.
- (c) Components shall be pneumatically tested at not less than 1.25 times their Design Pressure.

ND-6322 Maximum Permissible Test Pressure

The maximum test pressure shall be limited as defined in ND-6222.

ND-6323 Test Pressure Holding Time

The test pressure of ND-6321 shall be maintained for a minimum total time of 10 min.

ND-6324 Examination for Leakage After Application of Pressure

Following the application of pressure for the time specified in ND-6323, the test pressure shall be reduced to a value equal to the greater of the Design Pressure or three-fourths of the test pressure, and held for a sufficient time to permit examination as defined in ND-6224.

ND-6330 BELLOWS EXPANSION JOINTS

When a pneumatic test is performed on a bellows expansion joint in lieu of a hydrostatic test, the requirements of ND-6230 shall be met.

ND-6400 PRESSURE TEST GAGES

ND-6410 REQUIREMENTS FOR PRESSURE TEST GAGES

ND-6411 Types of Gages to Be Used and Their Location

Pressure test gages used in pressure testing shall be indicating pressure gages and shall be connected directly to the component. If the indicating gage is not readily visible to the operator controlling the pressure applied, an additional indicating gage shall be provided where it will be visible to the operator throughout the duration of the test. For systems with a large volumetric content, it is recommended that a recording gage be used in addition to the indicating gage.

ND-6412 Range of Indicating Pressure Gages

(a) Analog-type indicating pressure gages used in testing shall be graduated over a range not less than $1\frac{1}{2}$ times nor more than 4 times the test pressure.

(b) Digital-type pressure gages may be used without range restriction provided the combined error due to calibration and readability does not exceed 1% of the test pressure.

ND-6413 Calibration of Pressure Gages

All test gages shall be calibrated against a standard dead weight tester or a calibrated master gage. The test gages shall be calibrated before each test or series of tests. A series of tests is that group of tests, using the same pressure test gage or gages, which are conducted within a period not exceeding 2 weeks.

ND-6500 ATMOSPHERIC AND 0-15 psig (0-103 kPa) STORAGE TANKS

ND-6510 TESTING OF ATMOSPHERIC STORAGE TANKS

ND-6511 Testing of Reinforcement Pads

Following the examination specified in ND-5282.5 and before filling the tank with test water, the reinforcement pads shall be tested by applying up to 15 psi (103 kPa) pneumatic pressure between the tank shell and the reinforcement plate on each opening, using the telltale hole; and while each such space is subject to such pressure, soapsuds, linseed oil, or other suitable material for detection of leaks shall be applied to all attachment welding around reinforcement, both inside and outside the tank.

ND-6512 Preparation for Testing

Preparation for testing of storage tanks shall conform to the requirements of ND-6120 as applicable. Flat bottoms supported directly on grade need not comply with ND-6121.

ND-6513 Hydrostatic Testing of Tank Shell

Upon completion of the tank, the shell shall be tested. For tanks with supported cone, self-supported cone, self-supported dome, and self-supported umbrella roofs, the tank shall be filled with water and inspected frequently during the filling operation. The filling height shall be 2 in. (51 mm) above the top leg of the angle.

Page 286

For tanks with flat roofs, the filling height shall be the liquid level for which the tank was designed or the bottom of any overflow which limits the filling height.

ND-6520 TESTING OF 0-15 psig (0-103 kPa) STORAGE TANKS

ND-6521 Testing of Reinforcement Pads

Following the examination specified in ND-5283.6 and before performing the preliminary pneumatic testing, the reinforcement pads shall be tested by using the same procedure as given in ND-6511.

ND-6522 Preparation for Testing

Preparation for testing of storage tanks shall conform to the requirements of ND-6120, as applicable. Flat bottoms supported directly on grade need not comply with ND-6121.

ND-6523 Preliminary Pneumatic Testing

Prior to the application of the hydrostatic or combination hydrostatic-pneumatic test, the tank shall be filled with air to a pressure of 2 psig (13.8 kPa) or one-half the pressure P_G for which the vapor space at the top of the tank is designed, whichever pressure is smaller. Soapsuds shall be applied to all joints in the tank wall above the high liquid design level. If any leaks appear, the defective condition shall be corrected and the applicable preliminary tightness test shall be repeated. In the case of a tank whose bottom rests directly on the tank grade without having anchor bolts provided near the

boundary of contact to hold it down, if the bottom at this boundary rises slightly off the foundation during the tightness test with air pressure in the tank, sand shall be tamped firmly under the bottom, while the tank is under pressure, to fill the gap so formed.

ND-6524 Combination Hydrostatic-Pneumatic Tests

The following requirements apply to tanks which have not been designed to be filled with liquid to a test level higher than their specified capacity level.

ND-6524.1 Pressurizing.

After the preliminary tests specified in ND-6523 have been completed, the pressure relief valve or valves shall be blanked off. With the top of the tank vented to atmosphere to prevent accumulation of pressure, the tank shall be filled with water to its high liquid level. The vents at the top of the tank shall then be closed and air shall be injected slowly into the top of the tank until the pressure in the vapor space is about one-half the pressure P_G for which this space is designed. Thereafter, the test pressure shall be increased in steps of approximately 2 psig (13.8 kPa) or one-fourth of the intended test pressure, whichever is the smaller, until the pressure in the vapor space is 1.25 times the pressure P_G for which this space is designed. Means shall be provided so that the required test pressure will not be exceeded.

ND-6524.2 Time at Pressure.

The pressure in the tank shall be held stationary for a reasonable time after the application of each increment of pressure as specified so as to provide an opportunity to examine the tank carefully for signs of distress. The maximum test pressure of 1.25 times the vapor space design pressure shall be held for at least 1 hr, after which the pressure shall be reduced slowly to the vapor space design pressure.

ND-6524.3 Soap Bubble Test.

The vapor space design pressure shall be held for a sufficient time to permit a close visual examination of all joints in the walls of the tank and of all welding around manways, nozzles, and other connections. In this examination, soapsuds shall be applied to all weld joints located above the high liquid design level for which the tank is designed, including the roof-to-sidewall joint. This examination is not required for welds subject to radiography.

ND-6524.4 Precautions to Be Employed in Pneumatic Testing.

An air test as specified in ND-6523 and in ND-6524 introduces some hazard. In view of the large amount of air which will be present during such a test, it is recommended that no one be permitted to go near the tank while the pressure is being applied for the first time in this test. While the pressure in the tank exceeds the pressure for which the vapor space is designed, the inspections should be made from a reasonable distance from the tank using optical aids, if necessary, for observations of particular areas.

ND-6525 Hydrostatic Test

The following requirements apply to tanks which have been designed and constructed to be filled with liquid to the top of the roof.

ND-6525.1 Filling.

Following the preliminary tests specified in ND-6523 the pressure relief valve or valves shall be blanked off. With the top of the tank vented

Page 287

to atmosphere, the tank shall be filled with water to the top of the roof, while allowing all air to escape in order to prevent accumulation of pressure. The vents on the tank shall be closed and the pressure in the tank shall be increased slowly until the hydrostatic pressure under the topmost point in the roof is 1.25 times the pressure P_G for which the vapor space is designed to withstand when in operation with the tank filled to its specified high liquid level.

ND-6525.2 Pressurizing.

Test pressure may be developed either by (a) or (b) below:

(a) pumping water into the tank with all vents closed;

(b) superimposing a vertical pipe, not less than NPS 6 (DN 150), above the top of the tank with an overflow located at such a height as to give the desired test pressure by static head alone and then filling the pipe to the level of said overflow.

ND-6525.3 Time at Pressure.

Test pressure shall be held for at least 1 hr. The hydrostatic pressure under the roof shall then be reduced to the Design Pressure and shall be held at this level for a sufficient time to permit close visual examination of all joints in the walls of the tank, and of all welding around manways, nozzles, and other connections.

ND-6526 Partial Vacuum Testing Procedure

Following the tests specified in ND-6524 or in ND-6525, the pressure in the tank shall be released and a manometer shall be connected to the vapor space. The ability of that part of the tank to withstand the partial vacuum for which it is designed shall then be checked by withdrawing water from the tank or by air evacuation, with all vents closed, until the design partial vacuum is developed. Careful observations shall be made under the above condition of loading to determine whether any appreciable changes occur in the shape of the tank.

ND-6530 TEST GAGES

ND-6531 Indicating Gage and Its Location

An indicating gage shall be connected directly to the topmost part of the roof on the tank under test, except that, in the case of a tank which is designed for storage of gases or vapors alone and is to be tested only with air, this gage may be connected to the tank at some lower level. If the indicating gage is not readily visible to the operator controlling the pressure applied, an additional indicating gage shall be provided where it will be visible to the operator throughout the duration of the test. Means shall be provided so that the required test pressure will not be exceeded.

ND-6532 Recording Gage and Its Location

A recording gage shall also be used on each tank and a record shall be kept of the pressures during all stages of the tests. This gage shall be connected either to the piping leading to the indicating gage or directly to the tank at a point near the indicating gage connection.

ND-6533 Accumulation of Static Head on Gages

In all cases in which a gage is mounted at a level lower than its connection to the tank or lower than some part of the piping leading to the gage, suitable precautions shall be taken to prevent accumulation of any static head of condensed moisture or water from other sources in the piping leads above the level of the gage.

ND-6534 Calibration of Pressure Test Gages

All test gages shall be calibrated against a standard deadweight tester or a calibrated master gage. The test gages shall be calibrated before each test or series of tests. A series of tests is that group of tests using the same pressure test gage or gages, which are conducted in a period not exceeding 2 weeks.

ND-6600 SPECIAL TEST PRESSURE SITUATIONS

ND-6610 COMPONENTS DESIGNED FOR EXTERNAL PRESSURE

Components designed for external pressure only shall be subjected to an internal test pressure at 1.25 times the design external pressure. The pressure shall be under proper control so that the required test pressure is never exceeded by more

than 6%.

ND-6620 PRESSURE TESTING OF COMBINATION UNITS

ND-6621 Pressure Chambers Designed to Operate Independently

Pressure chambers of combination units that have been designed to operate independently shall be pressure

Page 288

tested as separate vessels; that is, each chamber shall be tested without pressure in the adjacent chamber.

ND-6622 Common Elements Designed for a Maximum Differential Pressure

(a) When pressure chambers of combination units have their common elements designed for the maximum differential pressure that can occur during startup, operation, and shutdown, and the differential pressure is less than the higher of the Design Pressures of the adjacent chambers, the common elements shall be subjected to a pressure test of at least 1.25 times the maximum differential pressure.

(b) Following the test of the common elements as required by ND-6622(a) and their inspection, the adjacent chambers shall be pressure tested (ND-6221). Care must be taken to limit the differential pressure between the chambers to the pressure used when testing the common elements.

ND-6900 PROOF TESTS TO ESTABLISH DESIGN PRESSURE

ND-6910 GENERAL REQUIREMENTS

ND-6911 Establishment by Test of Design Pressure

The Design Pressure for components and piping or component parts for which the strength cannot be computed with a satisfactory assurance of accuracy, shall be established in accordance with the requirements of this Subarticle, using one of the test procedures applicable to the type of loading and to the material used in construction.

ND-6911.1 Types of Proof Tests.

Provision is made in these rules for two types of tests to determine the internal Design Pressure:

(a) tests based on yielding of the part to be tested (these tests are limited to materials with a ratio of specified minimum yield to specified minimum ultimate strength of 0.625 or less);

(b) tests based on bursting of the part.

ND-6911.2 Purpose for Which Proof Tests May Be Used.

The tests in this Subarticle may be used only for the purpose of establishing the Design Pressure of those elements or component parts for which the thickness cannot be determined by means of the design rules given in this Subsection. The Design Pressure of all other elements or component parts shall not be greater than that determined by means of the applicable design rules.

ND-6911.3 Permissible Previous Pressurization of Component or Part.

The component or component part for which the Design Pressure is to be established shall not previously have been subjected to a pressure greater than $1\frac{1}{2}$ times the desired or anticipated Design Pressure adjusted for Design Temperature as provided in ND-6911.9.

ND-6911.4 Test Requirements for Duplicate Components or Parts.

When the Design Pressure of a component or component part has been established by a proof test, duplicate parts of the same materials, design, and construction need not be proof tested but shall be given a hydrostatic test in accordance with ND-6200 or a pneumatic test in accordance with ND-6300. The dimensions and minimum thickness of the structure

to be tested shall not vary materially from those actually used. A geometrically similar part may be qualified by a series of tests covering the complete size range of the pressure part.

ND-6911.5 Application of Pressure.

In the procedures given in ND-6921, ND-6923, and ND-6924, the hydrostatic pressure in the component or component part shall be increased gradually until approximately one-half the anticipated Design Pressure is reached. Thereafter, the test pressure shall be increased in steps of approximately one-tenth or less of the anticipated Design Pressure until the pressure required by the test procedure is reached. The pressure shall be held stationary at the end of each increment for a sufficient time to allow the observations required by the test procedure to be made and shall be released to zero to permit determination of any permanent strain after any pressure increment that indicates an increase in strain or displacement over the previous equal pressure increment.

ND-6911.6 Check of Measurements.

As a check that the measurements are being taken on the most critical areas, the Inspector may require a lime wash or other brittle coating to be applied on all areas of probable high stress concentrations in the test procedures given in ND-6923 and ND-6924. The surfaces shall be suitably cleaned before the coating is applied in order to obtain satisfactory adhesion. The technique shall be suited to the coating material.

ND-6911.7 Determination of Design Pressure for Components or Parts Having Corrosion Allowance.

The test procedures in this Subarticle give the Design Pressure for the thickness of material tested. When the

Page 289

thickness as tested includes extra thickness as provided in ND-3121, the Design Pressure at which the component shall be permitted to operate shall be determined by multiplying the Design Pressure obtained from the test by the ratio:

$$(t - c)/t$$

where

t	= nominal thickness of the material at the weakest point, in.
c	= allowance added for corrosion, erosion, and abrasion, in.

ND-6911.8 Determination of Yield Strength and Tensile Strength

(a) For proof tests based on yielding (ND-6921, ND-6923, or ND-6924), the yield strength (or yield point for those materials which exhibit that type of yield behavior indicated by a "sharp-kneed" portion of the stress-strain diagram) of the material in the part tested shall be determined in accordance with the method prescribed in the applicable material specification and as described in ASTM E 8-1972. For proof tests based on bursting, ND-6922, the tensile strength instead of the yield strength of the material in the part tested shall be similarly determined.

(b) Yield or tensile strength so determined shall be the average from three or four specimens cut from the part tested after the test is completed. The specimens shall be cut from a location where the stress during the test has not exceeded the yield strength. The specimens shall not be flame cut because this might affect the strength of the material. If yield or tensile strength is not determined by test specimens from the pressure part tested, alternative methods are given in ND-6921, ND-6922, ND-6923, and ND-6924 for evaluation of proof test results to establish the Design Pressure.

(c) When excess stock from the same piece of wrought material is available and has been given the same stress relieving heat treatment as the pressure part, the test specimens may be cut from this excess stock. The specimens shall not be removed by flame cutting or any other method involving sufficient heat to affect the properties of the specimen.

ND-6911.9 Design Pressure at Higher Temperatures.

The Design Pressure for components and component parts that are to operate at temperatures at which the allowable stress value of the material is less than at the test temperature shall be determined by the following formula:

where

P_o	= Design Pressure at the Design Temperature, psig
P_t	= Design Pressure at test temperature, psig
S_o	= maximum allowable stress value at the Design Temperature, psi
S_t	= maximum allowable stress value at test temperature, psi

ND-6912 Retests

A retest shall be allowed on a duplicate component or component part if errors or irregularities are obvious in the test results.

ND-6913 Witnessing of Tests by Inspector

Tests to establish the Design Pressure of components or component parts shall be witnessed and approved by the Inspector.

ND-6914 Safety Precautions

Safety of testing personnel should be given serious consideration when conducting proof tests, and particular care should be taken during bursting tests in ND-6922.

ND-6920 PROCEDURES

[98]

ND-6921 Brittle Coating Test Procedure

(a) Subject to the limitations of ND-6911.1(a), this procedure may be used only for components and component parts under internal pressure, constructed of materials having a definitely determinable yield point. The component parts that require proof testing shall be coated with a lime wash or other brittle coating in accordance with ND-6911.6. Pressure shall be applied in accordance with ND-6911.5. The parts being proof tested shall be examined between pressure increments for signs of yielding as evidenced by flaking of the brittle coating or by the appearance of strain lines. The application of pressure shall be stopped at the first sign of yielding or, if desired, at some lower pressure.

(b) The Design Pressure P in psig at test temperature for components or component parts tested under ND-6921 shall be computed as stipulated in (1) through (4) below.

Page 290

(1) If the average yield strength is determined in accordance with ND-6911.8:

$$P = 0.5H \frac{Y_s}{Y_a}$$

(2) To eliminate the necessity of cutting tensile specimens and determining the actual yield strength of the material under test, one of the following equations may be used to determine the Design Pressure.

(a) For carbon steel meeting an acceptable specification in Section II, Part D, Subpart 1, Tables 1A, 1B, and 3 with a specified minimum tensile strength of not over 70.0 ksi:

$$P = 0.5H \left(\frac{S}{S + 5000} \right) \quad (1)$$

(1)

(b) For any other acceptable material listed in Section II, Part D, Subpart 1, Tables 1A, 1B, and 3:

$$(2) P = 0.4H$$

where

H	= hydrostatic test pressure at which the test was stopped, psig
Y_s	= specified minimum yield strength, psi
Y_a	= actual average yield strength from test specimens, psi
S	= specified minimum tensile strength, psi

(3) When Eq. (1) or (2) is used, the material in the pressure part shall have had no appreciable cold working or other

treatment that would tend to raise the yield strength above the normal value.

(4) The Design Pressure at other temperatures shall be determined as provided in ND-6911.9.

[98]

ND-6922 Bursting Test Procedure

(a) This procedure may be used for components or component parts under internal pressure when constructed of any material permitted to be used under the rules of this Subsection. The Design Pressure of any component part proof tested by this method shall be established by a hydrostatic test to failure by rupture of a full-size sample of such pressure part. The hydrostatic pressure at which rupture occurs shall be determined.

(b) The Design Pressure P in psig at test temperature for parts tested under ND-6922 shall be computed as stipulated in (1) through (3) below.

(1) Parts constructed of materials other than cast materials:

$$P = \frac{B}{5} \times \frac{SE}{S_{ave}} \quad \text{or} \quad P = \frac{B}{5} \times \frac{SE}{S_{max}} \quad (3)$$

(3)

(2) Parts constructed of cast materials, except cast iron and cast nodular iron which are not permitted:

$$P = \frac{Bf}{5} \times \frac{SE}{S_{ave}} \quad \text{or} \quad P = \frac{Bf}{5} \times \frac{SE}{S_{max}} \quad (4)$$

(4)

where

B	= bursting test pressure, psig
E	= efficiency of welded joint, if used (ND-3352-1)
f	= casting quality factor (ND-3115)
S	= specified minimum tensile strength, psi
S_{ave}	= average actual tensile strength of test specimens, psi

$S_{\max}$

= maximum tensile strength of range of specification, psi

(3) The Design Pressure at other temperatures shall be determined as provided in ND-6911.9.

ND-6923 Strain Measurement Test Procedure

(a) Subject to limitations of ND-6911.1(a), this procedure may be used for components or component parts under internal pressure, constructed of any material permitted to be used under the rules of this Subsection. Strains shall be measured in the direction of the maximum stress at the most highly stressed parts (see ND-6911.6) by means of strain gages of any type capable of indicating strains to 0.00005 in./in. Pressure shall be applied as provided in ND-6911.5.

(b) After each increment of pressure has been applied, readings of the strain gages and the hydrostatic pressure shall be taken and recorded. The pressure shall be released and any permanent strain at each gage shall be determined after any pressure increment that indicates an increase in strain for this increment over the previous equal pressure increment. Only one application of each increment of pressure is required.

(c) Two curves of strain against test pressure shall be plotted for each gage line as the test progresses, one showing the strain under pressure and one showing the permanent strain when the pressure is removed. The test may be discontinued when the test pressure reaches the value H which will, by the equation, justify the desired Design Pressure, but shall not exceed the pressure at which the plotted points for the most highly

Page 291

strained gage line reach the value given below for the material used:

(1) 0.2% permanent strain for aluminum-base and nickel-base alloys

(2) 0.2% permanent strain for carbon low alloy and high alloy steels

(3) 0.5% strain under pressure for copper-base alloys

(d) The Design Pressure P in psig at test temperature for parts tested under this paragraph shall be computed as stipulated in (1) through (3) below.

(1) If the average yield strength is determined in accordance with ND-6911.8:

$$P = 0.5H \left(\frac{Y_s}{Y_a} \right) \quad (5)$$

(5)

(2) If the actual average yield strength is not determined by test specimens:

$$(6) P = 0.4H$$

where

H

= hydrostatic test pressure at which the test was stopped in accordance with (c) above, psig

Y_s

= specified minimum yield strength, psi

Y_a

= actual average yield strength from test specimens, psi

(3) The Design Pressure at other temperatures shall be determined as provided in ND-6911.9.

[98]

ND-6924 Displacement Measurement Test Procedure

(a) Subject to the limitations of ND-6911.1(a), this procedure may be used only for components and component parts under internal pressure, constructed of materials having a definitely determinable yield point. Displacement shall be measured at the most highly stressed parts (ND-6911.6) by means of measuring devices of any type capable of measuring to 0.001 in. The displacement may be measured between two diametrically opposed reference points in a symmetrical structure or between a reference point and a fixed base point. Pressure shall be applied as provided in ND-6911.5.

(b) After each increment of pressure has been applied, readings of the displacement and hydrostatic test pressure shall be taken and recorded. The pressure shall be released, and any permanent displacement shall be determined after any pressure increment that indicates an increase in measured displacement for this increment over the previous equal pressure increment. Only one application of each increment is required. Care must be taken to assure that the readings represent only displacements of the parts on which measurements are being made, and do not include any slip of the measuring devices or any movement of the fixed base points or of the pressure part as a whole.

(c) Two curves of displacement against test pressure shall be plotted for each reference point as the test progresses, one showing the displacement under pressure and one showing the permanent displacement when the pressure is removed. The application of pressure shall be stopped when it is evident that the curve through the points representing displacement under pressure has deviated from a straight line.

(d) The pressure coincident with the proportional limit of the material shall be determined by noting the pressure at which the curve representing displacement under pressure deviates from a straight line. The pressure at the proportional limit may be checked from the curve of permanent displacement by locating the point where the permanent displacement begins to increase regularly with further increases in pressure. Permanent deformation at the beginning of the curve that results from the equalization of stresses and irregularities in the material may be disregarded.

(e) The Design Pressure P in psig at test temperature for parts tested under this paragraph shall be computed as stipulated in (1) through (4) below.

(1) If the average yield strength is determined in accordance with ND-6911.8:

$$P = 0.5H \frac{Y_s}{Y_a} \quad (7)$$

(7)

(2) To eliminate the necessity of cutting tensile specimens and determining the actual yield strength of the material

under test, Eq. (8) or (9) may be used to determine the Design Pressure.

(a) For carbon steel, meeting an acceptable specification in Section II, Part D, Subpart 1, Tables 1A, 1B, and 3 with a specified minimum tensile strength of not over 70.0 ksi:

$$P = 0.5H \left(\frac{S}{S + 5000} \right) \quad (8)$$

(8)

(b) For any other acceptable material listed in Section II, Part D, Subpart 1, Tables 1A, 1B, and 3:

Page 292

$$(9) P = 0.4H$$

where

H	= hydrostatic test pressure coincident with the proportional limit of the weakest element of the component part test, psig
Y_s	= specified minimum yield strength, psi
Y_a	= actual average yield strength from test specimens, psi
S	= specified minimum tensile strength, psi

(3) When Eq. (8) or (9) is used, the material in the pressure part shall have had no appreciable cold working or other treatment that would tend to raise the yield strength above the normal value.

(4) The Design Pressure at other temperatures shall be determined as provided in ND-6911.9.

[98]

ND-6930 PROCEDURE FOR COMPONENTS HAVING CHAMBERS OF SPECIAL SHAPE SUBJECT TO COLLAPSE

(a) Pressure chambers of components, portions of which have a shape other than that of a complete circular cylinder or formed head, and also jackets of cylindrical vessels which extend over only a portion of the circumference, which are not fully staybolted as required by ND-3133 and ND-3329, shall withstand without excessive deformation a hydrostatic test of not less than 3 times the desired Design Pressure.

(b) The Design Pressure at other temperatures shall be determined as provided in ND-6911.9.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 ND-7000

ND-7100 GENERAL REQUIREMENTS

ND-7110 SCOPE

(a) A system¹ shall be protected from the consequences arising from the application of conditions of pressure and coincident temperature that would cause the Design Pressure specified in the Design Specification to be exceeded.

(b) Pressure relief devices are required when the operating conditions considered in the Overpressure Protection Report would cause the Service limits specified in the Design Specification to be exceeded.

(c) Protection of components in the system from the effects of pressure increases of extremely short duration, such as water hammer resulting from the rapid closing of a valve, is beyond the scope of this Article and should be included in the Design Specification.

ND-7111 Definitions

(a) Overpressure, as used in this Article, can consist of either one of the following pressure changes:

(1) an increase in system fluid pressure, resulting from thermal imbalances, excess pump flow, and other similar phenomena, capable of causing a system pressure increase of a sufficient duration to be compatible with the dynamic response characteristics of the pressure relief devices listed in this Article; or

(2) changes in differential pressure resulting from thermal imbalances, vapor condensation, and other similar phenomena, capable of causing an internal or external pressure increase of sufficient duration to be compatible with the dynamic response characteristics of the pressure relief devices.

(b) The definitions of pressure relief devices as specified in this Article are in accordance with ASME PTC 25-1994.

¹ Wherever the word system appears in this Article it refers to the component or group of components for which overpressure protection is provided as described in the Overpressure Protection Report.

(c) *Primary pressure* is the pressure of the fluid at the inlet of the pressure relief device.

(d) *Secondary pressure* is that value of pressure existing in the passage between the actual discharge area and the outlet for which the discharge system of the pressure relief devices shall be designed.

ND-7120 INTEGRATED OVERPRESSURE PROTECTION

Overpressure protection of the component shall be provided by one of the following methods as an integrated overpressure protection:

(a) the use of pressure relief devices and associated pressure sensing elements;

(b) a component design not exceeding the service limits specified in the Design Specification [ND-7111(b)].

ND-7130 PROVISIONS FOR CHECKING OPERATION OF PRESSURE RELIEF DEVICES

ND-7131 Design Provisions

Reclosing pressure relief devices shall be designed so that potential impairment of the overpressure protection function from service exposure to fluids can be determined by test or examination.

ND-7132 Construction Provisions

Reclosing pressure relief devices shall be so constructed and installed that their correct operation and the reliability of their associated pressure sensing elements under Service or Test Conditions can be demonstrated as may be required by regulatory and enforcement authorities having jurisdiction at the nuclear power plant site.

ND-7140 INSTALLATION PROVISIONS

ND-7141 Installation of Pressure Relief Devices

(a) Pressure relief devices shall be installed at a location as close as practicable to the major source of overpressure anticipated to arise within the pressure retaining boundary of the system under the conditions summarized in the Overpressure Protection Report (ND-7200).

(b) The connection between a component and its pressure relief valve shall have a minimum inside diameter equal to or greater than the nominal inside diameter of the pressure relief valve inlet. The opening in the connection shall be designed to provide direct and unobstructed flow between the component and the pressure relief valve.

(c) The connection between a safety valve and the component it protects shall be not longer than the face-to-face dimension of the corresponding tee fitting of the same diameter and pressure rating listed in ANSI B16.5, ANSI B16.9, or ANSI B16.11, or any length that would cause cumulative line losses of 2% of the relieving pressure. The connection between a safety relief valve or a relief valve and the component it protects shall be such that the accumulated line losses do not exceed 3% of the relieving pressure.

(d) Safety, safety relief, and relief valves shall be installed in an upright position.

(e) The inside areas of the discharge piping from a pressure relief device shall not be less than the inside area of the valve outlet. The size and length of the discharge piping shall be such that any back pressure that may exist or develop will not reduce the relieving capacity of the relieving device(s) below that required to protect the component(s). In the determination of the back pressure, potential for flashing shall be considered.

(f) Valve installation not in accordance with (c), (d), and (e) above may be used provided:

(1) the NV Certificate Holder confirms that the valve design is satisfactory for the valve installation and satisfies the requirements of the valve Design Specification;

(2) the valves are adjusted for acceptable performance and in conformance with the requirements of the valve Design Specification;

(3) technical justification for the adequacy of the installation is provided in the Overpressure Protection Report, including verification that the requirements of (1) and (2) above have been met.

(g) When a rupture disk device is used as the sole pressure relief device, the nominal pipe size of the connections on either side of the rupture disk device shall not be less than the nominal size of the rupture disk device, unless the smaller size connecting pipe is taken into account in determining the capacity of the device.

(h) Rupture disk devices used as the sole pressure relieving device may be installed in any position provided the medium is such that any accumulation of material at the inlet of the rupture disk devices will not impair the proper burst and opening of the rupture disk.

ND-7142 Provisions When Stop Valves Are Used

No stop valve or other device shall be placed relative to a pressure relief device so that it could reduce the overpressure protection below that required by the rules of this Article, unless such stop valves are constructed and installed with controls and interlocks so that the relieving capacity requirements of ND-7300 are met under all conditions of operation of both the system and the stop valves. Means shall be provided such that the operation of controls and interlocks can be verified.

ND-7143 Provisions for Draining Pressure Relief Devices

(a) A pressure relief device installation, whose design is such that liquid or residue can collect on the discharge side of the device and where such liquid or residue could interfere with proper relieving operation, shall be fitted with a drain at the lowest point where the liquid or residue may collect.

(b) If the design of a pressure relief valve is such that liquid or residue can collect on the discharge side of the disk and could interfere with proper relieving operation, the valve shall be fitted with a drain at the lowest point where liquid or residue may collect.

ND-7150 ACCEPTABLE PRESSURE RELIEF DEVICES²

ND-7151 Pressure Relief Valves³

Pressure relief valves may be used in accordance with ND-7170 and ND-7500.

2 A pressure relief device is designed to open to prevent a rise of internal fluid pressure in excess of a specified value due to exposure to emergency or upset conditions. It may be a pressure relief valve, a nonreclosing pressure relief device, or a vacuum relief valve.

3 A pressure relief valve is a pressure relief device which is designed to reclose and prevent the further flow of fluid after normal conditions have been restored.

Page 299

ND-7152 Vacuum Relief Valves

Vacuum relief valves may be used in accordance with ND-7170 and ND-7500.

ND-7153 Nonreclosing Pressure Relief Devices⁴

Nonreclosing pressure relief devices may be used in accordance with ND-7170 and ND-7600.

ND-7160 UNACCEPTABLE PRESSURE RELIEF DEVICES

ND-7161 Deadweight Pressure Relief Valves

Deadweight valves shall not be used.

ND-7170 PERMITTED USE OF PRESSURE RELIEF DEVICES

ND-7171 Valve Types Permitted for Steam Service

Any of the following types or combination of types of pressure relief devices may be used to provide the required relieving capacity:

- (a) safety valves⁵ meeting the requirements of ND-7510;
- (b) pilot operated pressure relief valves⁶ meeting the requirements of ND-7520;
- (c) power actuated pressure relief valves⁷ meeting the requirements of ND-7530;
- (d) safety valves with auxiliary actuating devices meeting the requirements of ND-7540;
- (e) safety relief valves,⁸ meeting the requirements of ND-7510.

4 A nonreclosing pressure relief device is a pressure relief device designed to remain open after operation.

5 A safety valve is a pressure relief valve actuated by inlet static pressure and characterized by rapid opening or pop action.

6 A pilot operated pressure relief valve is a pressure relief valve in which the major relieving device is combined with and controlled by a self-actuated auxiliary pressure relief valve.

7 A power actuated pressure relief valve is a pressure relief valve in which the major relieving device is combined with and controlled by a device requiring an external source of energy.

8 A safety relief valve is a pressure relief valve characterized by rapid opening or pop action, or by opening generally proportional to the increase in pressure over the opening pressure.

ND-7172 Valve Types Permitted for Air and Gas Service

(a) Safety, safety relief, pilot operated, or power actuated pressure relief valves may be used, provided that they comply with the requirements of ND-7500.

(b) Pilot operated or power actuated pressure relief valves may be used, provided that the design is such that the main valve will open automatically at not over the set pressure and will discharge its full rated capacity if some essential part of the pilot or actuator should fail.

(c) Vacuum relief valves⁹ may be used, provided that they comply with the requirements of ND-7500.

ND-7173 Valve Types Permitted for Liquid Service

Safety relief, relief,¹⁰ pilot operated, or power actuated pressure relief valves may be used, provided that they comply with the requirements of ND-7500.

ND-7174 Nonreclosing Devices

(a) Rupture disk devices¹¹ may be used on liquid, air, gas, or steam service, except for main steam service, in accordance with ND-7600.

(b) Application on liquid service shall be evaluated to ensure that the design of the rupture disk device and that the fluid energy of the system on which it is installed will provide adequate opening to meet the requirements of ND-7300.

ND-7200 OVERPRESSURE PROTECTION REPORT

ND-7210 RESPONSIBILITY FOR REPORT

The provisions intended to meet the requirements of this Article shall be the subject of an Overpressure Protection report prepared by the Owner or his Designee.

9 A vacuum relief valve is a pressure relief device designed to admit fluid to prevent an excessive internal vacuum; it is designed to reclose and prevent further flow of fluid after normal conditions have been restored.

10 A relief valve is a pressure relief valve actuated by inlet static pressure and having a gradual lift generally proportional to the increase in pressure over the opening pressure.

11 A rupture disk device is a nonreclosing pressure relief device actuated by inlet static pressure and designed to function by the bursting of a pressure containing disk.

Page 300

ND-7220 CONTENT OF REPORT

The Overpressure Protection Report shall define the protected systems and the integrated overpressure protection provided. As a minimum, the Report shall include (a) through (f) below:

(a) identification of the specific ASME Code Section III, Article ND-7000, Edition and Addenda and applicable Code Cases used in the design of the overpressure protection system;

(b) drawings showing arrangement of the protected systems, including the pressure relief devices employed;

(c) the range of operating conditions, including the effect of discharge piping back pressure under which the pressure relief devices are required to function;

(d) an analysis of the conditions that give rise to the maximum pressure or vacuum relieving requirements, except where the basis for establishing relieving capacity is the loss of the heat sink of the protected system when the thermal input to the system is at a maximum;

(e) consideration of burst pressure tolerance and manufacturing design range of the rupture disk device;

(f) the relief capacity required to prevent a pressure or vacuum rise in any component from exceeding the limitations of ND-7300;

(g) the redundancy and independence of the pressure relief devices and their associated pressure or vacuum sensors and controls employed to preclude a loss of overpressure protection in the event of a failure of any pressure relief device, sensing element, associated control, or external power source.

ND-7230

The report, after it has been reconciled with the requirements of this Subsection, shall be certified by one or more Registered Professional Engineers competent in the applicable field of design and qualified in accordance with the requirements of Appendix XXIII of Section III Appendices.

ND-7240 REVIEW OF REPORT AFTER INSTALLATION

(a) Any modification of the installation from that used for preparation of the Overpressure Protection Report shall be reconciled with the Overpressure Protection Report.

(b) Modifications shall be documented in an addendum to the Overpressure Protection Report. The addendum shall contain a copy of the as-built drawing and shall include either:

- (1) a statement that the as-built system meets the requirements of the Overpressure Protection Report; or
- (2) a revision to the Overpressure Protection Report to make it agree with the as-built system; or
- (3) a description of the changes made to the as-built system to make it comply with the Overpressure Protection Report.

(c) The addendum shall be certified by one or more Registered Professional Engineers competent in the applicable field of design and qualified in accordance with the requirements of Appendix XXIII of Section III Appendices.

ND-7250 FILING OF REPORT

A copy of the Overpressure Protection Report shall be filed at the nuclear power plant site prior to the Inspector signing the Owner's Data Report. The report shall be made available to the Authorized Inspector and the enforcement authorities having jurisdiction at the plant site.

ND-7300 RELIEVING CAPACITY REQUIREMENTS

ND-7310 TOTAL RATED RELIEVING CAPACITY FOR SYSTEM UPSET CONDITIONS

ND-7311 Relieving Capacity of Pressure Relief Devices

(a) The total rated relieving capacity of the pressure relief devices (certified in accordance with ND-7700, intended for overpressure protection within the scope of this Subsection, and credited in conformance with ND-7500 or ND-7600) shall take into account any limitations due to fluid flow through piping and other components.

(b) The total rated relieving capacity shall be sufficient to prevent a rise in pressure of more than 10% above the Design Pressure of any component within the pressure retaining boundary of the protected system under any system upset conditions.

(c) The rated capacity of each vacuum relief valve shall not be less than that required to prevent a differential pressure in excess of the value specified in the Design Specification.

Page 301

ND-7312 Relieving Capacity of Pressure Relief Devices Used With Pressure Reducing Devices

When pressure reducing devices are used, the relieving capacity of the pressure relief devices shall be based on (a) and (b) below.

(a) Pressure reducing devices shall be considered fully open, including open bypass piping, if provided.

(b) The discharge from the low pressure portion shall be considered blocked downstream of the pressure reducing device.

ND-7313 Required Number and Capacity of Pressure Relief Devices

(a) Systems or components requiring individual protection may be served by one or more devices.

(b) When more than one device is used, no device shall have a capacity less than 50% of the device with the largest capacity.

ND-7314 Required Number and Capacity of Pressure Relief Devices for Isolatable Components Requiring Overpressure Protection

(a) The required relieving capacity for overpressure protection of an individual component that is isolatable shall be secured by the use of at least one pressure relief device meeting the requirements of ND-7500 or ND-7600, as applicable.

(b) Certain types of valves have the capability of trapping liquid in the body or bonnet cavity. If such a cavity accumulates liquid and there is an increase in the adjacent system temperature, an increase in pressure in the body or bonnet cavity may result (ND-3511).

ND-7315 Relieving Capacity of Vacuum Relief Valves

(a) The rated capacity of each vacuum relief valve shall not be less than that required to prevent a differential pressure in excess of the value specified in the Design Specification.

(b) At least two independent vacuum relief valves shall be provided on each system. The capacity of each vacuum relief valve shall not be less than that required to protect the system.

(c) Systems designed to withstand the maximum differential pressure do not require vacuum relief valves.

ND-7320 TOTAL RATED RELIEVING CAPACITY FOR SYSTEM EMERGENCY CONDITIONS

ND-7321 Relieving Capacity of Pressure Relief Devices

(a) The total rated relieving capacity of the pressure relief devices (certified in accordance with ND-7700, intended for overpressure protection within the scope of this Subsection, and credited in conformance with ND-7500 or ND-7600) shall take into account any limitations due to fluid flow through piping and other components.

(b) The total rated relieving capacity shall be sufficient to prevent a rise in pressure of more than 10% above the Design Pressure of any component within the pressure retaining boundary of the protected system under any system emergency conditions.

ND-7322 Relieving Capacity of Vacuum Relief Valves

(a) The rated capacity of each vacuum relief valve shall not be less than that required to prevent a differential pressure in excess of the value specified in the Design Specification.

(b) At least two independent vacuum relief valves shall be provided on each system. The capacity of each vacuum relief valve shall not be less than that required to protect the system.

(c) Systems designed to withstand the maximum differential pressure do not require vacuum relief valves.

ND-7330 SYSTEM FAULTED CONDITIONS

This Article does not provide rules for overpressure protection of system faulted conditions.

ND-7400 SET PRESSURES OF PRESSURE RELIEF DEVICES

ND-7410 SET PRESSURE LIMITATIONS FOR UPSET CONDITIONS

The set pressure of at least one of the pressure relief devices connected to the system shall not be greater than the Design Pressure of any component within the pressure retaining boundary of the protected system. Additional pressure relief devices may have higher pressure settings, but in no case shall these settings be such that the total accumulated pressure exceeds the system limitations specified in ND-7310.

ND-7420 SET PRESSURE FOR EMERGENCY CONDITIONS

The establishment of set pressure shall take into account the requirements of ND-7320.

ND-7500 OPERATING DESIGN REQUIREMENTS FOR PRESSURE AND VACUUM RELIEF VALVES

ND-7510 SAFETY, SAFETY RELIEF, AND RELIEF VALVES

ND-7511 General Requirements

ND-7511.1 Spring-Loaded Valves.

Valves shall open automatically by direct action of the fluid pressure as a result of forces acting against a spring.

ND-7511.2 Balanced Valves.

Balanced valves, whose operation is independent of back pressure, may be used if means are provided to verify the integrity of the balancing devices.

ND-7512 Safety Valve Operating Requirements

ND-7512.1 Antichattering and Lift Requirements.

Safety valves shall be constructed to operate without chattering and to attain rated lift at a pressure which does not exceed the set pressure by more than 3% or 2 psi, whichever is greater.

ND-7512.2 Opening Pressure Tolerance

(a) The opening pressure tolerance plus or minus shall not exceed the following: 2 psi (13.8 kPa) for pressures up to and including 70 psi (483 kPa); 3% for pressures over 70 psi (483 kPa) to 300 psi (2070 kPa); 10 psi (69 kPa) for pressures over 300 psi (2070 kPa) to 1000 psi (6900 kPa); and 1% for pressures over 1000 psi (6900 kPa). The set pressure tolerance shall apply unless a greater tolerance is established as permissible in the Overpressure Protection Report (ND-7200) and in the safety valve Design Specification (NCA-3250).

(b) Conformance with the requirements of (a) above shall be established for each production valve by test. Steam valves shall be tested on steam.

ND-7512.3 Blowdown Requirements.

Safety valves shall be adjusted to close after blowing down to a pressure not lower than that specified in the valve Design Specification (NCA-3250) and the basis for the setting is covered in the Overpressure Protection Report (NB-7200). The adjustment shall be determined by test or by proration from the Certificate Holder's blowdown test data.

ND-7513 Safety Relief and Relief Valve Operating Requirements

Safety relief and relief valves shall be constructed to attain rated lift at a pressure which does not exceed the set pressure by more than 10% or 3 psi (20.6 kPa), whichever is greater.

ND-7513.1 Opening Pressure Tolerance

(a) The opening pressure tolerance plus or minus from the set pressure of safety relief and relief valves shall not exceed 2 psi (13.8 kPa) for pressures up to and including 70 psi (483 kPa) and 3% for pressures above 70 psi (483 kPa). The set pressure tolerance shall apply unless a greater tolerance is established as permissible in the Overpressure Protection Report (ND-7200) and in the valve Design Specification (NCA-3250).

(b) Conformance with the requirements of (a) above shall be established for each production valve by test. Steam

valves shall be tested on steam, air or gas valves on air or gas, and liquid valves on liquid.

ND-7513.2 Blowdown Requirements.

Safety relief and relief valves shall be adjusted to close after blowing down to a pressure not lower than that specified in the valve Design Specification (NCA-3250) and the basis for the setting shall be covered in the Overpressure Protection Report (ND-7200). The adjustment shall be determined by test or by proration from the Certificate Holder's blowdown test data.

ND-7514 Relieving Capacity

The relieving capacity of pressure relief valves of the types permitted in this Subarticle shall be based on the stamped relieving capacity and proration of capacity as determined by ND-7700.

ND-7515 Sealing of Adjustments

Means shall be provided in the design of all valves for sealing all adjustments or access to adjustments which can be made without disassembly of the valve. For a pilot operated pressure relief valve, an additional seal shall be provided to seal the pilot and main valve together. Seals shall be installed by the Certificate Holder at the time of initial adjustment. Seals shall be installed in a manner to prevent changing the adjustment or disassembly of the valve without breaking the seal.

Page 303

The seal shall serve as a means of identifying the Certificate Holder making the initial adjustment.

ND-7520 PILOT OPERATED PRESSURE RELIEF VALVES

ND-7521 General Requirements

Pilot operated pressure relief valves shall operate independently of any external energy source.

ND-7522 Operating Requirements

ND-7522.1 Actuation.

The pilot control device shall be actuated directly by the fluid pressure of the protected system.

ND-7522.2 Response Time.

The Overpressure Protection Report (ND-7200) shall include the effects of divergence between opening (set) and closing (blow down) pressures of the pilot valve and the pressures at which the main valve attains rated lift and closes. These divergences are caused by the inherent time delay (i.e., response time) between the operation of the pilot and the main valve, and the rate of the system pressure change. The limits for response time shall be specified in the valve Design Specification (NCA-3250).

ND-7522.3 Main Valve Operation.

The main valve shall operate in direct response to the pilot control device. The valve shall be constructed to attain rated lift under stable conditions at pressures that do not exceed the set pressure by more than 3% or 2 psi, whichever is greater, for steam, and 10% or 3 psi, whichever is greater, for air, gas, or liquid service.

ND-7522.4 Sensing Mechanism Integrity.

For other than spring loaded direct acting pilot control devices, means shall be provided to detect failure of the pressure sensing element, such as bellows, when operation of the pilot control device is dependent upon the integrity of a pressure sensing element.

ND-7522.5 Set Pressure Tolerance

(a) The set pressure tolerance shall apply only to the pilot valve.

(b) The set pressure tolerance plus or minus shall not exceed the following: 2 psi (13.8 kPa) for pressures up to and including 70 psi (483 kPa); 3% for pressures over 70 psi (483 kPa) for liquid valves and 3% for pressures over 70 psi (483 kPa) up to and including 300 psi (2070 kPa); 10 psi (69 kPa) for pressures over 300 psi (2070 kPa) up to and including 1000 psi (6900 kPa); and 1% for pressures over 1000 psi (6900 kPa) for steam, air, and gas valves. The set pressure tolerance as stated shall apply unless a greater tolerance is established as permissible in the Overpressure Protection Report (ND-7200) and in the valve Design Specification (NCA-3250).

(c) Conformance with the requirements of (b) above shall be established for each production valve by test. Steam valves shall be tested on steam, air, or gas valves on air or gas, and liquid valves on liquid.

ND-7522.6 Blowdown

(a) The blowdown requirements shall only apply to the pilot valve.

(b) Pilot operated valves shall be adjusted to close after blowing down to a pressure not lower than that specified in the valve Design Specification (NCA-3250) and the basis for the setting is covered in the Overpressure Protection Report (ND-7200).

(c) The adjustment shall be determined by test or by proration from the Certificate Holder's blowdown test data.

ND-7523 Credited Relieving Capacity

The credited relieving capacity of pilot operated pressure relief valves shall be based on the certified relieving capacity. In addition, the capacity may be prorated as permitted in ND-7700.

ND-7524 Sealing of Adjustments

The sealing requirements of ND-7515 shall apply.

ND-7530 POWER ACTUATED PRESSURE RELIEF VALVES

ND-7531 Use

Power actuated pressure relief valves, which depend upon an external energy source such as electrical, pneumatic, or hydraulic systems and which respond to signals from pressure or temperature sensing devices, may be used, provided the requirements of this Subsubarticle are met.

ND-7532 Minimum Required Number

At least two valves shall be used to contribute to the required relieving capacity.

ND-7533 Sensors and Controls

(a) The sensors, controls, and external energy sources for valve operation shall have redundancy and independence

Page 304

at least equal to that required for the control and safety protection systems associated with the system.

(b) The relief valve and its auxiliary devices treated as a combination shall comply with the following requirements.

(1) The valve opening pressure shall be controlled within a tolerance as specified in ND-7512.2 of the set pressure when the automatic control is in use.

(2) The valve blowdown shall be controlled to a pressure not lower than that specified in the valve Design Specification (NCA-3250).

ND-7534 Relieving Capacity

ND-7534.1 System Upset Conditions.

For system upset conditions, the relieving capacity with which these valves are credited shall be not more than:

- (a) the stamped relieving capacity of the smaller one when two valves are installed;
- (b) one-half of the total stamped relieving capacity when three or more valves are installed.

ND-7534.2 System Emergency Conditions.

For system emergency conditions, the relieving capacity with which these valves are credited shall not be more than:

- (a) the relieving capacity of the valve with the smaller stamped capacity where two valves are installed;
- (b) the relieving capacity of all except the valve with the largest stamped capacity for valves where three through ten valves are installed;
- (c) the relieving capacity of all except two valves of the largest stamped capacity where more than ten valves are installed.

ND-7535 Response Time

In systems protected by power operated pressure relief valves, consideration shall be given to the time lapse between the signal to open and achieving the fully opened position and to the time lapse between the signal to close and achieving the fully closed position.

ND-7540 SAFETY AND SAFETY RELIEF VALVES WITH AUXILIARY ACTUATING DEVICES

ND-7541 Use

Safety and safety relief valves with auxiliary actuating devices which operate independently of the spring loading of the valve may be used, provided the requirements of ND-7510 are met except as modified by this Subsubarticle.

ND-7542 Construction and Design

- (a) The construction shall be such that the valve opens automatically by direct action of the fluid at a pressure not higher than the safety valve set pressure and relieves at the rated relieving capacity in the event of failure of any essential part of the valve's auxiliary devices.
- (b) The design of the auxiliary actuating device shall be such that the safety valve will not be prevented from operating as defined in ND-7510 when the auxiliary actuating device is deenergized.

ND-7550 VACUUM RELIEF VALVES

Vacuum relief valves shall meet the construction requirements applicable to Class 3 valves and the additional requirements of this Article.

ND-7552 Types Permitted

- (a) Balanced self-actuating horizontally installed swinging disk valves.
- (b) Vertically installed vacuum disk or pallet-type valves.
- (c) All vacuum relief valves shall have provisions for adjustment of the differential pressure.

ND-7753 Operating Requirements

Vacuum relief valves, which are operated by indirect means depending on an external energy source, such as electrical, pneumatic, or hydraulic systems, are not acceptable unless at least two independent external power operated valves and

control systems are employed so that the required relieving capacity is obtained if any one of the valves or systems should fail to operate.

ND-7600 REQUIREMENTS FOR NONRECLOSING PRESSURE RELIEF DEVICES

ND-7610 GENERAL REQUIREMENTS

ND-7611 Use of Rupture Disk Devices

Rupture disk devices certified in accordance with ND-7720 and ND-7750 are subject to the following.

Page 305

(a) Rupture disk devices may be used as the sole pressure relief device for services where release of the contents of the protected system is acceptable to the enforcement authority having jurisdiction at the nuclear power plant site.

(b) Rupture disk devices may be used on the inlet side of pressure relief valves only when such valves are of the full bore¹² type (ND-7623).

(c) Rupture disk devices may be used in conjunction with pressure relief valves on the outlet side (ND-7624).

ND-7612 Burst Pressure Tolerance

The burst pressure tolerance at the specified disk temperature¹³ shall not exceed ± 2 psi (± 13.8 kPa) for stamped burst pressure up to and including 40 psi (276 kPa) and $\pm 5\%$ for stamped burst pressure above 40 psi (276 kPa) as established by the rules of ND-7613, unless other values have been established in the Design Specification and are covered in the Overpressure Protection Report.

ND-7613 Tests to Establish Stamped Burst Pressure

(a) Every rupture disk shall have a stamped burst pressure established by rules of ND-7612 within a manufacturing design range,¹⁴ at a specified disk temperature, and shall be stamped with a lot number.

(b) Each lot of rupture disks shall be tested in accordance with one of the following methods. All tests of disks for a given lot shall be made in a holder of the same form and pressure area dimensions as that being used in service.

(1) At least two sample rupture disks from each lot of rupture disks¹⁵ shall be burst at the specified disk temperature. The stamped burst pressure shall be determined so that the sample rupture disk burst pressures are within the tolerance specified by ND-7612.

12 A pressure relief valve which has no protrusions in the bore and wherein the valve disk lifts to an sufficient for the minimum area, at any section at or below the body seat, to become the controlling orifice.

13 The specified disk temperature supplied to the rupture disk manufacturer shall be the temperature of the disk is expected to burst.

14 The manufacturing design range is a range of pressure within which the stamped burst pressure must fall. This range is included in the Design Specification and the Overpressure Protection Report.

15 A lot of rupture disks is those disks manufactured of material at one time, of the same size, thickness, type, heat, and manufacturing process including heat treatment.

(2) At least four sample rupture disks, but not less than 5% from each lot of rupture disks, shall be burst at four different temperatures distributed over the applicable temperature range for which the disks will be used. This data shall be used to establish a smooth curve of burst pressure versus temperature for the lot of disks. The burst pressure for each data point shall not deviate from the curve more than the burst pressure tolerance specified in ND-7612.

The value for the stamped burst pressure shall be established from the curve for a specified disk temperature.

(3) For prebulged solid metal disks or graphite disks only, at least four sample rupture disks using one size of disk from each lot of material shall be burst at four different temperatures, distributed over the applicable temperature range for which this material will be used. This data shall be used to establish a smooth curve of burst pressure versus temperature for the lot of material. The burst pressure for each data point shall not deviate from the curve more than the burst pressure tolerance specified in ND-7612.

At least two disks from each lot of disks, made from this lot of material and of the same size as those to be used, shall be burst at the ambient temperature to establish the room rating of the lot of disks. The curve shall be used to establish the stamped rating at the specified disk temperature for the lot of disks.

ND-7614 Burst Pressure in Relation to Pressure Relief Valve Set Pressure

The burst pressure of a rupture disk may be either lower or higher than the set pressure of the associated pressure relief valve, but in no case shall the rupture disk burst pressure and valve set pressure be such that the total accumulated pressure during full capacity relief exceeds the permitted limit (ND-7400).

ND-7620 INSTALLATION REQUIREMENTS

ND-7621 Provisions for Venting or Draining

The space between the rupture disk and the associated pressure relief valve shall be vented and/or drained. This space shall be provided with means to monitor its internal pressure during service periods.

ND-7622 System Obstructions

When the release of rupture disk material may occur, piping and other components downstream of the rupture disk shall be constructed such that no obstruction can

Page 306

be caused nor the function of a pressure relief valve impaired.

ND-7623 Rupture Disk Devices at the Inlet Side of Pressure Relief Valves

A rupture disk device may be installed at the inlet side of a pressure relief valve if the provisions of (a) through (c) below are met.

(a) The combination of the pressure relief valve and the rupture disk device capacity shall meet the requirements of ND-7300.

(b) The stamped burst pressure at the specified disk temperature of the rupture disk does not exceed the limits of ND-7400.

(c) The opening provided through the rupture disk after burst is sufficient to permit a flow equal to the capacity of the valve, and there is no chance of interference with proper functioning of the valve; but in no case shall this area be less than the area of the inlet of the valve unless the capacity and functioning of the specific combination of rupture disk and valve have been established by test in accordance with ND-7700.

ND-7624 Rupture Disk Devices at the Outlet Side of Pressure Relief Valves

A rupture disk device may be installed at the outlet side of pressure relief valves if the provisions of (a) through (d) below are met.

(a) The valve operation is independent of back pressure; or for unbalanced valves the set pressure of the valve plus the stamped bursting pressure of the rupture disk plus any pressure in the outlet piping does not exceed the limits of ND-7400.

(b) The relieving capacity meets the requirements of ND-7300.

(c) The stamped bursting pressure of the rupture disk at the specified disk temperature plus any pressure in the outlet piping from the rupture disk device shall not exceed the secondary Design Pressure of the outlet portion of the pressure relief valve and any pipe or fittings between the valve and the rupture disk device. However, in no case shall the stamped bursting pressure of the rupture disk at the operating temperature plus any pressure in the outlet piping from the rupture disk device exceed the limits of ND-7400.

(d) The opening provided through the rupture disk device after burst is sufficient to permit a flow equal to the rated capacity of the pressure relief valve.

ND-7700 CERTIFICATION REQUIREMENTS

ND-7710 RESPONSIBILITY FOR CERTIFICATION OF PRESSURE AND VACUUM RELIEF VALVES

(a) The Certificate Holder shall be responsible for having the relieving capacity of valves certified as prescribed in this Subarticle.

(b) Capacity certification which is obtained in compliance with other Subsections and which complies with this Subsection may be considered as qualified for capacity certification under these rules, and the valve may be stamped with the appropriate symbol of this Subsection.

ND-7720 RESPONSIBILITY FOR CERTIFICATION OF NONRECLOSING PRESSURE RELIEF DEVICES

(a) When rupture disk devices are used as the sole pressure relief device, the rupture disk device manufacturer shall be responsible for having the relieving capacity of the rupture disk device determined (ND-7760).

(b) When rupture disk devices are used at the inlet of pressure relief valves, the manufacturer of the rupture disk devices or the pressure relief valves shall be responsible for having the relieving capacity of the combination determined (ND-7760).

ND-7730 CAPACITY CERTIFICATION OF PRESSURE RELIEF VALVES - COMPRESSIBLE FLUIDS

ND-7731 General Requirements

ND-7731.1 Capacity Certification

(a) Capacity certification procedures shall be as required in ND-7732 through ND-7736.

(b) For steam at pressures over 1500 psig and up to 3200 psig, the value of K used to determine the certified relieving capacity shall be multiplied by:

$$(0.1906P - 1000)/(0.2292P - 1061)$$

where

P = set pressure, psig

This correction is also applicable to the certified relieving capacity as determined by the curve method.

Page 307

ND-7731.2 Test Media

(a) Capacity certification tests of pressure relief valves for steam service shall be conducted with dry saturated steam. For test purposes, the limits of 98% minimum quality and 20°F (11°C) maximum superheat shall apply. Capacity shall be corrected to the dry saturated condition from within these limits.

(b) Capacity certification tests for pressure relief valves for air and gas service shall be conducted with air, gas, or dry saturated steam.

ND-7731.3 Test Pressure

(a) Capacity certification tests of pressure relief valves for main steam service shall be conducted at a pressure which does not exceed the set pressure by more than 3% or 2 psi (13.8 kPa), whichever is greater.

(b) Capacity certification tests of pressure relief valves for air, gas, or steam service other than main steam service shall be conducted at a pressure which does not exceed the set pressure by more than 10% or 3 psi (20.6 kPa), whichever is greater.

ND-7731.4 Blowdown.

Valves having an adjustable blowdown construction shall be adjusted prior to testing so that the blowdown does not exceed 5% of the set pressure.

ND-7731.5 Drawings.

Prior to tests, the Certificate Holder shall submit drawings showing the valve construction to the Authorized Observer. The Authorized Observer shall submit the drawings and test results to the ASME designee for review and acceptance.

ND-7731.6 Design Changes.

When changes are made in the design of a pressure relief valve in such a manner as to affect the flow path, lift, or performance characteristics of the valve, new tests in accordance with this Article shall be performed.

ND-7732 Flow Model Test Method - Pilot or Power Operated Valves

ND-7732.1 Flow Capacity.

In those cases where test facility limitations make it impossible to perform capacity tests of the full-scale pressure relief valves, flow models of three different sizes may be utilized as a basis for capacity certification. Such flow models shall be sized consistent with the capabilities of the approved test laboratory at which the tests will be conducted and shall accurately model those features, such as orifice size, valve lift, and internal flow configuration, which affect flow capacity. The test models need not be functional pressure relief valves, provided that other tests to demonstrate proper function of the valve design are conducted as prescribed in ND-7732.2. The relieving capacity of valve designs certified by use of flow models shall be established by the coefficient of discharge method similar to that outlined in ND-7734. The certified relieving capacity of all sizes and pressures of a given design for which the value of K has been established, based on flow model tests in accordance with the method of ND-7734, shall not exceed the value calculated by the appropriate formula in ND-7734.2 multiplied by the coefficient K .

ND-7732.2 Demonstration of Function.

The function of three valves of the design to be certified shall be demonstrated by tests. Such tests may be performed in conjunction with the capacity certification tests outlined above or as separate tests using production valves. The purpose of these tests is to demonstrate to the satisfaction of a designated representative of the ASME that the valve will open at set pressure within the required opening pressure tolerance, will achieve full lift, and will reclose within required blowdown. If required by test facility limitations, these tests may be conducted at reduced flow capabilities. Measurement of valve blowdown may not be possible.

ND-7733 Slope Method

(a) For pressure relief valves of a specific design, four valves of each combination inlet size and orifice size shall be tested. These four valves shall be set at pressures that will cover the appropriate range of pressures for which the valves are to be used or within the range of the authorized test facility.

(b) The instantaneous slope of each test point shall be calculated and averaged, where slope is defined as the measured capacity divided by the absolute inlet pressure. If any of the experimentally determined slopes fall outside of a range of $\pm 5\%$ of the average slope, the unacceptable valves shall be replaced by two valves of the same size and set pressure. Following the test of these valves, a new average slope shall be determined, excluding the replaced valve test results. If any individual slope is now outside of the $\pm 5\%$ range, then the tests shall be considered unsatisfactory and shall be cause for the ASME designee to refuse certification of the particular valve design. The certified capacity shall be 90% of the average slope multiplied by the flow rating pressure, psia.

ND-7734 Coefficient of Discharge Method

A coefficient K may be established for a specific pressure relief valve design according to the procedure given in the

ND-7734.1 Number of Valves to Be Tested.

For each design, at least three valves for each of three different sizes shall be submitted for test. Each valve of a given size shall be set at a different pressure.

ND-7734.2 Establishment of Coefficient of Discharge

(a) Tests shall be made on each pressure relief valve to determine its lift, opening, and blowdown pressures, and capacity in terms of the fluid used in the test. A coefficient of discharge K_D shall be established for each test run as follows:

$$K_D = \frac{\text{Actual Flow}}{\text{Theoretical Flow}} = \text{Coefficient of Discharge}$$

where Actual Flow is determined quantitatively by test, and the Theoretical Flow is calculated by the following formula.

For test with dry saturated steam:

Pressures up to 1500 psig

$$W_T = 51.5AP$$

Pressures over 1500 psig and up to 3200 psig the value of W_T , calculated by the above equation, shall be corrected by being multiplied by the following factor:

$$\frac{(0.1906P - 1000)}{(0.2292P - 1061)}$$

For test with air:

$$W_T = 356AP \sqrt{\frac{M}{T}}$$

For test with gas:

$$W_T = CAP \sqrt{\frac{M}{ZT}}$$

where

W_T

= Theoretical Flow, lb/hr

A

= actual discharge area through the valve at developed lift, sq in.

C

= constant for gas or vapor which is a function of the ratio of specific heats

P

= (set pressure $\times$ 1.03) plus atmospheric pressure, psia, or set pressure plus 2 psi plus atmospheric pressure, whichever is greater, for test pressures determined by ND-7731.3(a)

= (set pressure $\times$ 1.10) plus atmospheric pressure, psia, or set pressure plus 3 psi plus atmospheric pressure, whichever is greater, for test pressures determined by ND-7731.3(b)

M

= molecular weight

T	= absolute temperature at inlet, °F + 460
k	= c_p/c_v ratio of specific heats (see Fig. XVIII-1110-1)
Z	= compressibility factor corresponding to P and T

The average of the coefficients of discharge K_D of the tests required shall be multiplied by 0.90 and their product shall be taken as the coefficient K of that design. The coefficient of the design shall not be greater than 0.876 (the product of 0.9×0.975).

(b) If any of the experimentally determined coefficients fall outside of a range of $\pm 5\%$ of the average coefficient, the unacceptable valves shall be replaced by two valves of the same size and set pressure. Following the test of these valves, a new average coefficient shall be determined, excluding the replaced valve test results. If any individual coefficient is now outside of the $\pm 5\%$ range, then the test shall be considered unsatisfactory and shall be cause for the ASME designee to refuse certification of the particular valve design.

ND-7734.3 Calculation of Certified Capacity

(a) The certified capacity of all sizes and pressures of a given design, for which the value of K has been established under the provisions of ND-7734.2 and which are manufactured subsequently, shall not exceed the value calculated by the appropriate formula multiplied by the coefficient K .

(b) The coefficient shall not be applied to valves whose beta ratio (the ratio of valve throat and inlet diameter) lies outside the range of 0.15 to 0.75, unless tests have demonstrated that individual coefficients of discharge, K_d , for valves of the extreme ends of a larger range is within $\pm 5\%$ of the average coefficient, K . For designs where lift is used to determine the flow area, all valves shall have the same nominal lift-to-seat diameter ratio (L/D).

ND-7735 Single Valve Method

ND-7735.1 Valve Capacity Within Test Facility Limits

(a) Where a single valve is to be capacity tested, the certified capacity may be based on three separate tests associated with each set pressure for which capacity certification is required.

(b) The certified capacity associated with each set pressure shall not exceed 90% of the average capacity established by the tests. Failure of the individual test capacities to fall within $\pm 5\%$ of the average capacity

Page 309

associated with each set pressure shall be cause for rejection of the test. The reason for the failure shall be determined and the test repeated.

(c) Should additional valves of the same design be constructed at a later date, the results of the tests on the original valve may be included as applicable to the particular test method selected.

ND-7735.2 Valve Capacity in Excess of Test Facility Limits

(a) For valves whose capacity exceeds that of the test facility, the certified capacity may be based on a flow coefficient K (ND-7734.2) determined from either blocked open flow tests or flow model tests, provided the orifice area is such that choked flow conditions are obtained. The certified capacity shall be calculated as directed in ND-7734.3.

(b) The proper operation of the valve shall be demonstrated as prescribed in ND-7732.2.

ND-7736 Proration of Capacity

(a) The capacity of a pressure relief valve applied to a system may be prorated to an overpressure greater than the overpressure for which the valve is certified. This overpressure shall be within the allowable limits of the system.

(b) Depending on the method used for the initial capacity certification:

(1) the prorated capacity shall be 90% of the average slope determined in ND-7733 multiplied by the prorated relieving

pressure (psia), or;

(2) the prorated capacity shall be calculated using the appropriate formula from ND-7734.2 (where P is the prorated relieving pressure (psia) multiplied by the coefficient K).

ND-7737 Capacity Conversions

The rated pressure relieving capacity of pressure relief valves for fluids other than the fluid used for certification shall be determined by the method of conversion given in Appendix XVIII-1000 except that valves for steam service shall be tested on steam.

ND-7738 Laboratory Acceptance of Pressure Relieving Capacity Tests

Tests shall be conducted at a place where the testing facilities, methods, procedures, and Authorized Observer (person supervising the tests) meet the applicable requirements of ASME PTC 25-1994. The tests shall be made under the supervision of and certified by an Authorized Observer. The testing facilities, methods, procedures, and qualifications of the Authorized Observer shall be subject to the acceptance of the ASME Boiler and Pressure Vessel Committee on recommendation of an ASME designee. Acceptance of the testing facility is subject to review within each 5 year period. Capacity test data shall be submitted to the ASME designee for review and acceptance.¹⁶

ND-7739 Laboratory Acceptance of Demonstration of Function Tests

The NV Certificate Holder shall assure that the tests are conducted at a place where the testing facilities, methods, and procedures provide for sufficient testing capacity and range of fluid properties so that the testing requirements of ND-7732.2 are met.

ND-7740 CAPACITY CERTIFICATION OF PRESSURE RELIEF VALVES - INCOMPRESSIBLE FLUIDS

ND-7741 General Requirements

ND-7741.1 Capacity Certification.

Capacity certification procedures shall be as required in ND-7742 through ND-7744.

ND-7741.2 Test Media.

The test medium to be used shall be water at a temperature between 40°F and 125°F (4°C and 52°C).

ND-7741.3 Test Pressure.

Tests shall be conducted at pressures which does not exceed the set pressure by more than 10% or 3 psi (20.6 kPa), whichever is greater.

ND-7741.4 Blowdown.

Blowdown shall be recorded at the time of the test.

ND-7741.5 Drawings.

Prior to tests, the Certificate Holder shall submit drawings showing the valve construction to the ASME designee for review and acceptance.

ND-7741.6 Design Changes.

When changes are made in the design of a pressure relief valve in such a manner as to affect the flow path, lift, or performance characteristics of the valve, new tests in accordance with this Article shall be performed.

¹⁶ Valve capacities published in "Pressure Relief Device Certifications." This publication may be obtained from the National Board of Boiler and Pressure Vessel Inspectors, 1055 Crupper Avenue,

ND-7742 Single Valve Method

Where a single valve at a single pressure is to be capacity tested, the capacity rating may be based on three separate tests of the single valve at the specified set pressure. The certified capacity rating of the valve shall not exceed 90% of the average capacity established by the tests. Failure of the individual test capacities to fall within $\pm 5\%$ of the average capacity may be cause for rejection of the test. The reason for the failure shall be determined and the test repeated.

Should additional valves of the same design be constructed at a later date, the results of the tests on the original valve may be included as applicable to the particular test method selected.

ND-7743 Slope Method

Four valves of each combination of pipe size and orifice size shall be tested. These four valves shall be set at pressures which cover the appropriate range of pressures for which the valves are to be used or within the range of the test facility. The instantaneous slope of each test point shall be calculated and averaged, where slope is defined as the measured capacity divided by the square root of the difference between the flow rating pressure and the valve discharge pressure. If any of the experimentally determined slopes fall outside of a range of $\pm 5\%$ of the average slope, the unacceptable valves shall be replaced by two valves of the same size and set pressure. Following the test of these valves, a new average slope shall be determined, excluding the replaced valve test results. If any individual slope is now outside of the $\pm 5\%$ range, then the tests shall be considered unsatisfactory and shall be cause for the ASME designee to refuse certification of the particular valve design. The certified capacity shall be 90% of the average slope multiplied by the square root of the difference between the flow rating pressure and the valve discharge pressure.

ND-7744 Coefficient of Discharge Method

Instead of individual capacity tests or the capacity curve method, a coefficient K may be established for a specific pressure relief valve design in accordance with the following subparagraphs.

ND-7744.1 Number of Valves to Be Tested.

For each design, three valves for each of three different sizes shall be tested, or a total of nine valves. Each valve of a given size shall be set at a different pressure.

ND-7744.2 Establishment of Coefficient of Discharge

(a) Tests shall be made on each relief valve to determine its lift, opening and closing pressures, and actual capacity in terms of pounds of water per hour. A coefficient of discharge K_D shall be established for each test run as follows:

$$K_D = \frac{\text{Actual Flow}}{\text{Theoretical Flow}} = \text{Coefficient of Discharge}$$

where Actual Flow is determined quantitatively by test and Theoretical Flow is calculated by the following formula.

For test with water:

$$W_t = 2407A\sqrt{(P - P_d)w}$$

where

W_t	= Theoretical Flow, lb/hr
A	= actual minimum discharge area through the valve at developed lift, sq in.
P	= (set pressure $\times$ 1.10) plus atmospheric pressure, psia, or set pressure plus 3 psi plus atmospheric pressure, whichever is greater
P_d	= pressure at discharge from valve, psia
w	= density of water at valve inlet conditions, lb/cu ft

The average of the coefficients of discharge K_D of the tests shall be multiplied by 0.90 and the product shall be taken as the coefficient K of the design. The coefficient of the design shall not be greater than 0.876 (the product of 0.9×0.975).

(b) If any of the experimentally determined coefficients fall outside of a range of $\pm 5\%$ of the average coefficient, the unacceptable valves shall be replaced by two valves of the same size and set pressure. Following the test of these valves, a new average coefficient shall be determined, excluding the replaced valve test results. If any individual coefficient is now outside of the $\pm 5\%$ range, then the test shall be considered unsatisfactory and shall be cause for the ASME designee to refuse certification of the particular valve design.

ND-7744.3 Calculation of Certified Capacity

(a) The certified capacity of all sizes and pressures of a given design for which the value of K has been established under the provisions of ND-7744.2 shall not exceed the value calculated by the theoretical formula above and multiplied by the coefficient K .

Page 311

(b) The coefficient shall not be applied to valves whose beta ratio (the ratio of valve throat and inlet diameter) lies outside the range of 0.15 to 0.75, unless tests have demonstrated that individual coefficients of discharge, K_D , for valves of the extreme ends of a larger range is within $\pm 5\%$ of the average coefficient, K . For designs where lift is used to determine the flow area, all valves shall have the same nominal lift-to-seat diameter ratio (L/D).

ND-7745 Laboratory Acceptance of Pressure Relieving Capacity Tests

Tests shall be conducted at a place where the testing facilities, methods, procedures, and Authorized Observer (person supervising the tests) meet the applicable requirements of ASME PTC 25-1994. The tests shall be made under the supervision of and certified by an Authorized Observer. The testing facilities, methods, procedures, and qualifications of

the Authorized Observer shall be subject to the acceptance of the ASME Boiler and Pressure Vessel Committee on recommendation of an ASME designee. Acceptance of the testing facility is subject to review within each 5 year period. Capacity test data shall be submitted to the ASME designee for review and acceptance.¹⁶

ND-7746 Proration of Capacity

(a) The capacity of a pressure relief valve applied to a system may be prorated to an overpressure greater than the overpressure for which the valve is certified. This overpressure shall be within the allowable limits of the system.

(b) Depending on the method used for the initial capacity certification:

(1) the prorated capacity shall be 90% of the average slope determined in ND-7742 multiplied by the prorated relieving pressure (psia), or;

(2) the prorated capacity shall be calculated using the appropriate formula from ND-7743.2 (where P is the prorated relieving pressure (psia) multiplied by the coefficient K).

ND-7750 CAPACITY CERTIFICATION OF VACUUM RELIEF VALVES

ND-7751 General Requirements

ND-7751.1 Capacity Certification.

Capacity certification procedures shall be as required in ND-7752 through ND-7755.

ND-7751.2 Test Media.

Capacity certification tests for vacuum relief valves for air and gas service shall be conducted with dry steam, air, or gas. For steam test purposes the limits of 98% minimum quality and 20°F (11°C) maximum superheat shall apply. Capacity shall be corrected to dry saturated condition from these limits.

ND-7751.3 Test Method and Pressure.

Capacity tests may be conducted by pressurizing the valve instead of using a vacuum, provided the inlet conditions of the valve (not the vessel) are known and the inlet pressure is not greater than 5 psi (35 kPa), and the direction of flow through the valve is the same on pressure as is experienced on vacuum. Tests shall be conducted at twice the set pressure or 1 psi (7 kPa), whichever is greater.

ND-7751.4 Blowdown.

Blowdown shall be recorded at the time of the test.

ND-7751.5 Drawings.

Prior to a test, the Certificate Holder shall submit drawings showing the valve construction to the Authorized Observer. The Authorized Observer shall submit the drawings and test results to the ASME designee for review and acceptance.

ND-7751.6 Design Change.

When changes are made in the design of a vacuum relief valve in such a manner as to affect the flow path, lift, or performance characteristics of the valve, new tests in accordance with this Article shall be performed.

ND-7752 Single Valve Method

(a) When a single valve at a single pressure is to be capacity tested, the capacity rating may be based on three separate and distinct tests of the single valve at the specified set pressure. The certified capacity rating of the valve shall not exceed 90% of the average capacity established by the tests. Failure of the individual test capacities to fall within $\pm 5\%$ of the average capacity shall be cause for rejection of the test. The reason for the failure shall be determined and the test repeated.

(b) Should additional valves of the same design be constructed at a later date, the results of the test on the original valve may be included as applicable to the particular test method selected.

ND-7753 Slope Method

Four valves of each combination of pipe size and orifice size shall be tested. These four valves shall be set at pressures which cover the appropriate range of pressures for which the valves are to be used or set within the range of the test facility. The slope of each

Page 312

test shall be calculated and averaged, where slope is defined as the measured capacity divided by the quantity, $F[(P)(P - P_o)]^{1/2}$

where

$$F = \sqrt{\left(\frac{k}{k-1}\right) (r^{2/k}) \left[\frac{1 - (r)^{\frac{k-1}{k}}}{1 - r} \right]}$$

P	= inlet pressure, psi
P_o	= discharge pressure, psi
k	= ratio of specific heats, c_p/c_v
r	= pressure ratio, P/P_o

If any of the experimentally determined slopes fall outside of a range of $\pm 5\%$ of the average slope, the unacceptable valves shall be replaced by two valves of the same size and set pressure. Following the test of these valves, a new average slope shall be determined, excluding the replaced valve test results. If any individual slope is now outside of the $\pm 5\%$ range, then the tests shall be considered unsatisfactory and shall be cause for the ASME designee to refuse certification of the particular valve design. The certified capacity shall be 90% of the average slope multiplied by the quantity, $F[(P)(P - P_o)]^{1/2}$.

ND-7754 Coefficient of Discharge Method

A coefficient K may be established for a specific vacuum relief valve design in accordance with ND-7754.1 and ND-7754.2.

ND-7754.1 Number of Valves to Be Tested.

For each design, three valves of three different sizes, a total of nine valves, shall be tested. Each valve of a given size shall be set at a different pressure.

ND-7754.2 Establishment of Coefficient of Discharge

(a) Tests shall be made on each relief valve to determine its lift, opening and closing pressures, and actual capacity. A coefficient of discharge K_D shall be established for each run as follows:

$$K_D = \frac{\text{Actual Flow}}{\text{Theoretical Flow}} = \text{Coefficient of Discharge}$$

where Actual Flow is determined quantitatively by test and Theoretical Flow is calculated from the appropriate equation for the test fluid. The following formula may be used for other than saturated steam flow:

$$W = 735FA \left[\frac{MP (P - P_o)}{T} \right]^{1/2}$$

$$Q = 279,000FA \left[\frac{P(P - P_o)}{MT} \right]^{1/2}$$

where

or is obtained from Fig. ND-7754.2(a)-1.

A	= flow area, sq in.
M	= molecular weight
P	= inlet pressure, psi
P_o	= discharge pressure, psi
T	= temperature, deg Rankin
k	= ratio of specific heats, C_v/C_p
r	= pressure ratio, P_o/P
Q	= cu ft/hr at 14.7 psi and 60°F
W	= lb/hr

The average of the coefficients of discharge K_D of the tests required shall be multiplied by 0.90 and their product shall be the coefficient K of that design. The coefficient of the design shall not be greater than 0.876 (the product of 0.9×0.975).

(b) If any of the experimentally determined coefficients fall outside of a range of $\pm 5\%$ of the average coefficient, the unacceptable valves shall be replaced by two valves of the same size and set pressure. Following the test of these valves, a new average coefficient shall be determined, excluding the replaced valve test results. If any individual coefficient is now outside of the $\pm 5\%$ range, then the test shall be considered unsatisfactory and shall be cause for the ASME designee to refuse certification of the particular valve design.

ND-7754.3 Calculation of Relieving Capacity

(a) The certified relieving capacity of all sizes and pressures of a given design, for which the value of K has been established, shall be calculated by the appropriate formula given above multiplied by the coefficient K . Values obtained from pressurized tests may be converted to equivalent vacuum from the above equation.

FIG. ND-7754.2(a)-1 VALUES OF F FOR NONCHOKING FLOW

FIG. ND-7754.2(a)-1 VALUES OF F FOR NONCHOKING FLOW

(b) The coefficient shall not be applied to valves whose beta ratio (the ratio of valve throat and inlet diameter) lies outside the range of 0.15 to 0.75, unless tests have demonstrated that individual coefficients of discharge, K_d , for valves of the extreme ends of a larger range is within $\pm 5\%$ of the average coefficient, K . For designs where lift is used to determine the flow area, all valves shall have the same nominal lift-to-seat diameter ratio (L/D).

ND-7755 Laboratory Acceptance of Relieving Capacity Tests

Tests shall be conducted at a place where the testing facilities, methods, procedures, and person supervising the tests (Authorized Observer) meet the applicable requirements of ASME PTC 25-1994. The tests shall be made under the supervision of, and certified by, an Authorized Observer. The testing facilities, methods, procedures, and qualifications of the Authorized Observer shall be subject to the acceptance of the ASME Boiler and Pressure Vessel Committee on recommendation of an ASME designee. Acceptance of the testing facility is subject to review within each 5 year period. Capacity test data shall be submitted to the ASME designee for review and acceptance.

ND-7760 CAPACITY DETERMINATION OF RUPTURE DISK DEVICES

ND-7761 General Requirements

ND-7761.1 Capacity Determination Procedures

- (a) Capacity determination procedures without flow tests shall be as given in ND-7762.1 and ND-7763.1.
- (b) Capacity determination procedures with flow tests shall be as required in ND-7762.2.

ND-7761.2 Test Media

- (a) Capacity tests of rupture disk devices for steam service shall be conducted with dry saturated steam. For test purposes, the limits of 98% minimum quality

Page 314

and 20°F (11°C) maximum superheat shall apply. Capacity shall be corrected to the dry saturated condition from within these limits.

- (b) Capacity tests for rupture disk devices for air and gas service shall be conducted with air, gas, or dry saturated steam.

ND-7761.3 Test Pressure.

Capacity tests of rupture disk devices shall be conducted at a pressure not exceeding 110% of the burst pressure.

ND-7761.4 Drawings.

Prior to tests, the Certificate Holder shall submit drawings showing the rupture disk device construction to the Authorized Observer. The Authorized Observer shall submit the drawings and test results to the ASME designee for review and acceptance.

ND-7761.5 Design Changes

- (a) When, in a type of rupture disk device, changes occur which may affect the flow area of the rupture disk device, each such change shall be treated as a different series of disks and must be tested.
- (b) When changes are made in the design of a type of rupture disk device in such a manner as to affect area or performance characteristics of the rupture disk device, new tests must be made.

ND-7762 Capacity Determination of Rupture Disk Devices in Combination With Pressure Relief Valves

ND-7762.1 Capacity Determination Without Flow Test

- (a) The rated capacity of the combination of a pressure relief valve when installed with a rupture disk device at the inlet side of the valve shall not exceed 80% of the certified capacity of the valve. Alternatively, the capacity of such a combination shall be established in accordance with ND-7762.2.
- (b) The rated capacity of the combination of a pressure relief valve when installed with a rupture disk device at the outlet of the valve shall be the certified capacity of the valve.

ND-7762.2 Capacity of Pressure Relief Valves in Combination With a Rupture Disk Device at the Inlet.

For each combination of pressure relief valve design and rupture disk device design, the Certificate Holder or the rupture disk device manufacturer shall have the capacity of the combination determined as prescribed in (a) and (b) below.

- (a) The Certificate Holder or the rupture disk device manufacturer shall submit for tests the smallest rupture disk device size with the equivalent size of pressure relief valve that is intended to be used as a combination device. The pressure relief valve to be tested shall have the largest orifice used in the particular inlet size.
- (b) Tests shall be performed in accordance with the requirements of (1) through (5) below. The rupture disk device and

pressure relief valve combination to be tested shall be arranged to duplicate the combination assembly design.

(1) The test shall be made using the minimum burst pressure of the rupture disk device design that is to be used in combination with the pressure relief valve design. The stamped bursting pressure shall be between 90% and 100% of the stamped set pressure of the valve.

(2) The test procedure to be used shall be as follows.

(a) The pressure relief valve by itself shall be tested for capacity without the rupture disk device at a pressure 10% above the valve set pressure.

(b) The rupture disk device shall then be installed in front of the pressure relief valve and the disk burst to operate the valve. The capacity test shall be performed on the combination at 10% above the valve set pressure duplicating the test of (a) above.

(3) The tests shall be repeated with two additional rupture disks of the same nominal rating for a total of three rupture disks to be tested with the single valve. The results of the test capacity shall fall within a range of 10% of the average capacity of the three tests. Failure to meet this requirement shall be cause to require retest for determination of cause of the discrepancies.

(4) From the results of the tests, a Combination Capacity Factor shall be determined. The Combination Capacity Factor is the ratio of the average capacity which is determined by the combination tests to the capacity which is determined by the test of (a) above. The Combination Capacity Factor shall be used as a multiplier to the certified capacity of the pressure relief valve in all sizes of the design except when a different factor has been established for larger sizes and other pressures in accordance with ND-7762.3. The value of the Combination Capacity Factor shall not be greater than one. The Combination Capacity Factor shall apply only to combinations of the same design and manufacture of the pressure relief valve and the same design and manufacture of the rupture disk device as those tested.

(5) The test laboratory shall submit the test results to the ASME designee for acceptance of the Combination Capacity Factor.

ND-7762.3 Optional Testing of Rupture Disk Devices and Pressure Relief Valves

(a) If desired, a Certificate Holder or a rupture disk manufacturer may conduct tests in the same manner

Page 315

as given in ND-7762.2 using the next two larger sizes of the same design of rupture disk device and pressure relief valve to determine a Combination Capacity Factor applicable to larger sizes. If a greater Combination Capacity Factor is established and can be approved, it may be used for all larger sizes of the combination, but the Factor shall not be greater than one.

(b) If desired, additional tests may be conducted at higher pressures in accordance with ND-7762.2 to establish a maximum Combination Capacity Factor to be used at all pressures higher than the highest tested, but the Factor shall not be greater than one.

ND-7763 Capacity of Rupture Disk Devices

ND-7763.1 Calculated Capacity

(a) The calculated capacity of a rupture disk device shall not exceed a value based on the applicable theoretical formula multiplied by a value for K of 0.62. For compressible fluids, see Appendix XVIII. The theoretical formula for liquids shall be as follows:

$$W_t = 2407A\sqrt{(P - P_d)w}$$

where

W_t	= Theoretical Flow, lb/hr
A	= minimum net flow area existing after rupture disk burst, sq in.
P	= (stamped rupture pressure $\times$ 1.10) plus atmospheric pressure, flow rating pressure, psia
P_d	= pressure at discharge from rupture disk device, psi
w	= specific weight of liquid at rupture disk device inlet conditions, lb/cu ft

(b) The minimum net flow area is the calculated net area after a complete burst of the rupture disk with appropriate allowance for any structural members which may reduce the net flow area through the rupture disk device. For sizing purposes, the net flow area shall not exceed the nominal pipe size area of the rupture disk device.

ND-7763.2 Tested Capacity. (In preparation.)

ND-7764 Laboratory Acceptance of Pressure Relieving Capacity Tests

Tests shall be conducted at a place where the testing facilities, methods, procedures, and Authorized Observer (person supervising the tests) meet the applicable requirements of ASME PTC 25-1994. The tests shall be made under the supervision of, and certified by, an Authorized Observer. The testing facilities, methods, procedures, and qualifications of the Authorized Observer shall be subject to the acceptance of the ASME Boiler and Pressure Vessel Committee on recommendation of an ASME designee. Acceptance of the testing facility is subject to review within each 5 year period. Capacity test data shall be submitted to the ASME designee for review and acceptance.

ND-7800 MARKING, STAMPING, AND DATA REPORTS

ND-7810 PRESSURE AND VACUUM RELIEF VALVES

ND-7811 Marking and Stamping

Each pressure relief valve shall be plainly marked by the Certificate Holder with the required data below in such a way that the marking will not be obliterated in service. The data shall be in characters not less than $\frac{3}{32}$ in. high. The marking shall be placed on the valve or on a nameplate securely fastened to the valve. The Code NV Symbol shall be stamped on the valve or nameplate, but the other required data may be stamped, etched, impressed, or cast. The marking shall include the following:

- (a) name, or an acceptable abbreviation, of the Certificate Holder
- (b) Certificate Holder's design or type number
- (c) size _____ (NPS, the nominal pipe size) of the valve inlet
- (d) set pressure _____ psi
- (e) certified capacity and overpressure in percent or psi in accordance with ND-7700

Pressure Relief Valves:

- lb/hr of saturated steam for valves certified on steam, or
- scfm (standard cubic feet per minute) at 60°F (16°C) and 14.7 psia of air for valves certified on air or gas, or
- gal/min of water at 70°F for valves certified on water

Vacuum Relief Valves:

- scfh (standard cubic feet per hour) at 60°F (16°C) and 14.7 psi (101 kPa)
- (f) applicable official Code Symbol Stamp, as shown in Table NCA-8100-1

In addition to the above, each pressure relief valve shall have a separate nameplate attached to the component that includes the marking requirements of NCA-8220 and ND-3593.2.

Page 316

ND-7812 Report Form for Pressure and Vacuum Relief Valves

A Data Report Form NV-1 shall be filled out and signed by the Certificate Holder and signed by the Inspector for each pressure and vacuum relief valve stamped with the Code NV Symbol.

ND-7820 RUPTURE DISK DEVICES

ND-7821 Rupture Disks

Every rupture disk shall be plainly marked by the manufacturer in such a way that the marking will not be obliterated in service. The rupture disk marking shall be placed on the flange of the rupture disk or on a metal tab permanently attached thereto.¹⁷ The marking shall include the following:

- (a) name or identifying trademark of the manufacturer
- (b) manufacturer's design or type number
- (c) lot number
- (d) size _____ in.
- (e) stamped bursting pressure _____ psi
- (f) specified disk temperature _____ °F
- (g) capacity _____ lb of saturated steam/hr or standard cu ft of air [60°F (16°C) and 14.7 psia (101 kPa)]/min
- (h) year built

ND-7822 Disk Holders (If Used)

Rupture disk holders shall be marked with the following:

- (a) name or identifying trademark of the manufacturer
- (b) manufacturer's design or type number

17 In lieu of marking all of the listed items on the flange or tab of each rupture disk, the marking may consist of a manufacturer's coding number sufficient to identify each rupture disk with a certificate or tab which includes the required information and is supplied with each lot of rupture disks.

(c) size _____ in.

(d) year built

(e) serial number

ND-7830 PRESSURE RELIEF VALVE IN COMBINATION WITH RUPTURE DISK DEVICES

ND-7831 Marking When Capacity Is Approved in Accordance With ND-7762.1

The marking shall be placed either on the valve or the rupture disk holder or on a plate or plates securely fastened to the valve or the rupture disk holder. The marking shall include a Combination Capacity Factor of 0.8.

ND-7832 Marking When Capacity Is Approved in Accordance With ND-7762.2

The following marking shall be in addition to the marking required by ND-7811 and ND-7822. The marking shall be placed on the valve or the rupture disk holder or on a plate or plates securely fastened to the valve or the rupture disk holder. The marking shall include the following:

(a) name of the Certificate Holder

(b) design or type or serial number of valve

(c) name of manufacturer of rupture disk device

(d) design or type designation of rupture disk device

(e) approved Combination Capacity Factor

ND-7840 CERTIFICATE OF AUTHORIZATION TO USE CODE SYMBOL STAMP

Each pressure and vacuum relief valve within the scope of this Article shall be constructed by a Certificate Holder possessing a Code NV Symbol Stamp and a valid Certificate of Authorization. Pressure and vacuum relief valves shall have the Code NV Symbol applied in accordance with the rules of ND-8100.

**IMPORTANT INFORMATION
ON THE 1998 BOILER AND
PRESSURE VESSEL CODE ADDENDA
DISTRIBUTION SCHEDULE**

There is a change in the way the Addenda to the 1998 Edition of the ASME Boiler and Pressure Vessel Code are distributed. The 1998 Edition, published July 1, 1998, incorporates the 1998 Addenda revisions, additions, or deletions. There will be no separate 1998 Addenda issued in a replacement page format. Two additional Addenda to the 1998 Edition, in the form of replacement pages, will be issued on July 1, 1999 and July 1, 2000.

The Summary of Changes published with the 1998 Edition lists and describes the revisions that are part of the 1998 Addenda. These changes are identified with a margin note, **98**, denoting the affected area.

The Addenda for 1999 and 2000 will also have a Summary of Changes and identifiers printed on the replacement pages. The revisions, additions, or deletions will be incorporated directly into the affected pages. It is advisable to retain the title sheets and all replaced pages for reference.

The effective dates for Code Editions and Addenda are described in the Foreword.

This code or standard was developed under procedures accredited as meeting the criteria for American National Standards. The Standards Committee that approved the code or standard was balanced to assure that individuals from competent and concerned interests have had an opportunity to participate. The proposed code or standard was made available for public review and comment which provides an opportunity for additional public input from industry, academia, regulatory agencies, and the public-at-large.

ASME does not "approve," "rate," or "endorse" any item, construction, proprietary device, or activity.

ASME does not take any position with respect to the validity of any patent rights asserted in connection with any items mentioned in this document, and does not undertake to insure anyone utilizing a standard against liability for infringement of any applicable Letters Patent, nor assume any such liability. Users of a code or standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, is entirely their own responsibility.

Participation by federal agency representative(s) or person(s) affiliated with industry is not to be interpreted as government or industry endorsement of this code or standard.

ASME accepts responsibility for only those interpretations issued in accordance with governing ASME procedures and policies which preclude the issuance of interpretations by individual volunteers.

The footnotes in this document are part of this American National Standard.

ADDENDA

Colored-sheet Addenda, which include additions and revisions to individual Sections of the Code, are published annually and will be sent automatically to purchasers of the applicable Sections up to the publication of the 2001 Code. The 1998 Code is available only in the loose-leaf format; accordingly, the Addenda will be issued in the loose-leaf, replacement-page format.

INTERPRETATIONS

ASME issues written replies to inquiries concerning interpretation of technical aspects of the Code. The Interpretations for each individual Section will be published separately and will be included as part of the update service to that Section. They will be issued semiannually (July and December) up to the publication of the 2001 Code. Interpretations of Section III, Divisions 1 and 2, will be included with the update service to Subsection NCA.

CODE CASES

The Boiler and Pressure Vessel Committee meets regularly to consider proposed additions and revisions to the Code and to formulate Cases to clarify the intent of existing requirements or provide, when the need is urgent, rules for materials or constructions not covered by existing Code rules. Those Cases which have been adopted will appear in the appropriate 1998 Code Cases book: (1) Boilers and Pressure Vessels and (2) Nuclear Components. Supplements will be sent automatically to the purchasers of the Code Cases books up to the publication of the 2001 Code.

Page v

FOREWORD

The American Society of Mechanical Engineers set up a committee in 1911 for the purpose of formulating standard rules for the construction of steam boilers and other pressure vessels. This committee is now called the Boiler and Pressure Vessel Committee.

The Committee's function is to establish rules of safety governing the design, fabrication, and inspection during construction of boilers and pressure vessels, and to interpret these rules when questions arise regarding their intent. In formulating the rules, the Committee considers the needs of users, manufacturers, and inspectors of pressure vessels. The objective of the rules is to afford reasonably certain protection of life and property and to provide a margin for deterioration in service so as to give a reasonably long, safe period of usefulness. Advancements in design and material and the evidence of experience have been recognized.

This Code contains mandatory requirements, specific prohibitions, and nonmandatory guidance for construction¹, and inservice inspection and testing activities. The Code does not address all aspects of these activities and those aspects which are not specifically addressed should not be considered prohibited. The Code is not a handbook and cannot replace education, experience, and the use of engineering judgment. The phrase *engineering judgment* refers to technical judgments made by

knowledgeable engineers experienced in the application of the Code. Engineering judgments must be consistent with Code philosophy and such judgments must never be used to overrule mandatory requirements or specific prohibitions of the Code.

Construction, as used in this Foreword, is an all-inclusive term comprising materials, design, fabrication, examination, inspection, testing, certification, and pressure relief.

The Committee recognizes that tools and techniques used for design and analysis change as technology progresses and expects engineers to use good judgment in the application of these tools. The designer is responsible for complying with Code rules and demonstrating compliance with Code equations when such equations are mandatory. The Code neither requires nor prohibits the use of computers for the design or analysis of components constructed to the requirements of the Code. However, designers and engineers using computer programs for design or analysis are cautioned that they are responsible for all technical assumptions inherent in the programs they use and they are responsible for the application of these programs to their design.

The Code does not fully address tolerances. When dimensions, sizes, or other parameters are not specified with tolerances, the values of these parameters are considered nominal and allowable tolerances or local variances may be considered acceptable when based on engineering judgment and standard practice as determined by the engineer.

The Boiler and Pressure Vessel Committee deals with the care and inspection of boilers and pressure vessels in service only to the extent of providing suggested rules of good practice as an aid to owners and their inspectors.

The rules established by the Committee are not to be interpreted as approving, recommending, or endorsing any proprietary or specific design or as limiting in any way the manufacturer's freedom to choose any method of design or any form of construction that conforms to the Code rules.

The Boiler and Pressure Vessel Committee meets regularly to consider revisions of the rules, new rules as dictated by technological development, Code Cases, and requests for interpretations. Only the Boiler and Pressure Vessel Committee has the authority to provide official interpretations of this Code. Requests for revisions, new rules, Code Cases, or interpretations shall be addressed to the Secretary in writing and shall give full particulars in order to receive consideration and action (see Mandatory Appendix covering preparation of technical inquiries). Proposed revisions to the Code resulting from inquiries will be presented to the Main Committee for appropriate action. The action of the Main Committee becomes effective only after confirmation by letter ballot of the Committee and approval by ASME.

Proposed revisions to the Code approved by the Committee are submitted to the American National Standards Institute and published in *Mechanical Engineering*

Page viii

to invite comments from all interested persons. After the allotted time for public review and final approval by ASME, revisions are published annually in Addenda to the Code.

Code Cases may be used in the construction of components to be stamped with the ASME Code symbol beginning with the date of their approval by ASME.

Code Editions may be used on or after the date of issue shown in the Edition. After Code revisions are approved by ASME, they may be used beginning with the date of issue shown on the Addenda. Revisions to material specifications are originated by the American Society for Testing and Materials (ASTM) and other recognized national or international organizations, and are usually adopted by ASME. However, those revisions may or may not have any effect on the suitability of material, produced to earlier editions of specifications, for use in ASME construction. ASME material specifications approved for use in each construction Code are listed in the Appendices of Section II, Parts A and B. These Appendices list, for each specification, the latest edition adopted by ASME, and earlier and later editions considered by ASME to be identical for ASME construction.

Owners of nuclear power plants are cautioned that Code Editions, Addenda, and Cases to be used in construction shall be acceptable to the regulatory and enforcement authorities having jurisdiction at the nuclear power plant site.

Each state and municipality in the United States and each province in Canada that adopts or accepts one or more Sections of the Boiler and Pressure Vessel Code is invited to appoint a representative to act on the Conference Committee to the Boiler and Pressure Vessel Committee. Since the members of the Conference Committee are in active contact with the administration and enforcement of the rules, the requirements for inspection in this Code correspond with those in effect in their respective jurisdictions. The required qualifications for an Authorized Inspector under these rules may be obtained from the

administrative authority of any state, municipality, or province which has adopted these rules.

The Boiler and Pressure Vessel Committee in the formulation of its rules and in the establishment of maximum design and operating pressures considers materials, construction, method of fabrication, inspection, and safety devices. Permission may be granted to regulatory bodies and organizations publishing safety standards to use a complete Section of the Code by reference. If usage of a Section, such as Section IX, involves exceptions, omissions, or changes in provisions, the intent of the Code might not be attained.

Where a state or other regulatory body, in the printing of any Section of the Boiler and Pressure Vessel Code, makes additions or omissions, it is recommended that such changes be clearly indicated.

The National Board of Boiler and Pressure Vessel Inspectors is composed of chief inspectors of states and municipalities in the United States and of provinces in Canada that have adopted the Boiler and Pressure Vessel Code. This Board, since its organization in 1919, has functioned to uniformly administer and enforce the rules of the Boiler and Pressure Vessel Code. The cooperation of that organization with the Boiler and Pressure Vessel Committee has been extremely helpful.

The Code Committee does not rule on whether a component shall or shall not be constructed to the provisions of the Code. The Scope of each Section has been established to identify the components and parameters considered by the Committee in formulating the Code rules. Laws or regulations issued by municipality, state, provincial, federal, or other enforcement or regulatory bodies having jurisdiction at the location of an installation establish the mandatory applicability of the Code rules, in whole or in part, within their jurisdiction. Those laws or regulations may require the use of this Code for vessels or components not considered to be within its Scope or may establish additions or deletions in that Scope. Accordingly, inquiries regarding such laws or regulations are to be directed to the issuing enforcement or regulatory body.

Questions or issues regarding compliance of a specific component with the Code rules are to be directed to the ASME Certificate Holder (Manufacturer). Inquiries concerning the interpretation of the Code are to be directed to the ASME Boiler and Pressure Vessel Committee. ASME is to be notified should questions arise concerning improper use of an ASME Code symbol.

The specifications for materials given in Section II are identical with or similar to those of specifications published by ASTM, AWS, and other recognized national or international organizations. When reference is made in an ASME material specification to a non-ASME specification for which a companion ASME specification exists, the reference shall be interpreted as applying to the ASME material specification. Not all materials included in the material specifications in Section II have been adopted for use in this Section. Usage is limited to those materials and grades listed in at least one of the tables of Section II, Part D, Subpart 1, identified as applicable to this Section. All materials allowed by this Section and used for construction within the scope of these rules shall be furnished in accordance with material specifications

Page ix

contained in Section II or referenced in Appendices A of Section II, Parts A and B except where otherwise provided in Code Cases or in this Section of the Code. Materials covered by these specifications are acceptable for use in items covered by the Code Sections only to the degree indicated in the applicable Section. Materials for Code use should preferably be ordered, produced, and documented on this basis. Material produced to an acceptable specification with requirements different from the requirements of the corresponding specification listed in Appendix A of Part A or Part B may also be used in accordance with the above, provided the material manufacturer or vessel manufacturer certifies with evidence acceptable to the Authorized Inspector that the corresponding ASME specification requirements of specifications listed in Appendix A of Part A or Part B have been met. Material produced to an acceptable material specification is not limited as to country of origin.

When required by context in this Section, the singular shall be interpreted as the plural, and vice-versa; and the feminine, masculine, or neuter gender shall be treated as such other gender as appropriate.

Publication of the SI (Metric) Edition of the ASME Boiler and Pressure Vessel Code was discontinued with the 1986 Edition. Effective October 1, 1986, the SI Edition was withdrawn as an ASME Boiler and Pressure Vessel Code document.

Page xi

STATEMENT OF POLICY ON THE USE OF CODE SYMBOLS AND CODE AUTHORIZATION IN ADVERTISING

ASME has established procedures to authorize qualified organizations to perform various activities in accordance with the

requirements of the ASME Boiler and Pressure Vessel Code. It is the aim of the Society to provide recognition of organizations so authorized. An organization holding authorization to perform various activities in accordance with the requirements of the Code may state this capability in its advertising literature.

Organizations that are authorized to use Code Symbols for marking items or constructions which have been constructed and inspected in compliance with the ASME Boiler and Pressure Vessel Code are issued Certificates of Authorization. It is the aim of the Society to maintain the standing of the Code Symbols for the benefit of the users, the enforcement jurisdictions, and the holders of the symbols who comply with all requirements.

Based on these objectives, the following policy has been established on the usage in advertising of facsimiles of the symbols, Certificates of Authorization, and reference to Code construction. The American Society of Mechanical Engineers does not "approve," "certify," "rate," or "endorse" any item, construction, or activity and there shall be no statements or implications which might so indicate. An organization holding a Code Symbol and/or a Certificate of Authorization may state in advertising literature that items, constructions, or activities "are built (produced or performed) or activities conducted in accordance with the requirements of the ASME Boiler and Pressure Vessel Code," or "meet the requirements of the ASME Boiler and Pressure Vessel Code."

The ASME Symbol shall be used only for stamping and nameplates as specifically provided in the Code. However, facsimiles may be used for the purpose of fostering the use of such construction. Such usage may be by an association or a society, or by a holder of a Code Symbol who may also use the facsimile in advertising to show that clearly specified items will carry the symbol. General usage is permitted only when all of a manufacturer's items are constructed under the rules.

The ASME logo, which is the cloverleaf with the letters ASME within, shall not be used by any organization other than ASME.

STATEMENT OF POLICY ON THE USE OF ASME MARKING TO IDENTIFY MANUFACTURED ITEMS

The ASME Boiler and Pressure Vessel Code provides rules for the construction of boilers, pressure vessels, and nuclear components. This includes requirements for materials, design, fabrication, examination, inspection, and stamping. Items constructed in accordance with all of the applicable rules of the Code are identified with the official Code Symbol Stamp described in the governing Section of the Code.

Markings such as "ASME," "ASME Standard," or any other marking including "ASME" or the various Code Symbols shall not be used on any item which is not constructed in accordance with all of the applicable requirements of the Code.

Items shall not be described on ASME Data Report Forms nor on similar forms referring to ASME which tend to imply that all Code requirements have been met when, in fact, they have not been. Data Report Forms covering items not fully complying with ASME requirements should not refer to ASME or they should clearly identify all exceptions to the ASME requirements.

MARINE CONFERENCE GROUP

J. Tiratto, *Chair*
C. F. Banks
L. W. Douthwaite
J. L. Jones
G. F. Wright

CONFERENCE COMMITTEE

D. E. Tanner - Tennessee (*Chair*)
R. D. Reetz - North Dakota (*Vice Chair*)
A. J. Justin - National Board of Boiler and Pressure Vessel Inspectors (*Secretary*)
R. J. Aben, Jr. - Michigan
J. S. Aclaro - Los Angeles, California
E. A. Anderson - Chicago, Illinois
J. Anderson - South Dakota
R. Barkdoll - Washington
F. P. Barton - Virginia
C. Castle - Nova Scotia, Canada
R. R. Cate - Louisiana
L. Chase - Northwest Territories, Canada
R. A. Coomes - Kentucky
J. Corcoran - Connecticut
M. H. Diehl, Jr. - Maryland
D. A. Douin - Illinois

D. Eastman - Newfoundland and Labrador, Canada

G. L. Ebeyer - New Orleans, Louisiana

F. Ellis - New Hampshire

E. Everett - Georgia

P. C. Hackford - Utah

D. Hanrath - North Carolina

J. B. Harlan - Delaware

K. Hynes - Prince Edward Island, Canada

D. T. Jagger - Ohio

D. J. Jenkins - Kansas

M. Kotb - Quebec, Canada

J. P. Larson - Minnesota

K. T. Lau - Alberta, Canada

J. Lemire - California

G. A. Lundberg - Florida

W. C. Lundine - Oregon

M. A. Malek - Maine

I. W. Mault - Manitoba, Canada

H. T. McEwen - Mississippi

A. W. Meiring - Indiana

R. Mile - Ontario, Canada

T. J. Monroe - Oklahoma

Y. Nagpaul - Hawaii

J. D. Payton - Pennsylvania

D. K. Peetz - Missouri

D. C. Price - Yukon Territory, Canada

R. S. Pucek - Wisconsin

T. E. Rennie - Arizona

L. Roussinos - British Columbia, Canada

M. Shuff - West Virginia

R. Snyder - New Jersey

N. Surtees - Saskatchewan, Canada

M. J. Verhagen - Wisconsin

R. B. West - Iowa

M. J. Wheel - Vermont

K. A. White - Nevada

R. K. White - New York

T. F. Wickham - Rhode Island

C. S. Withers - Colorado

ORGANIZATION OF SECTION III

1. GENERAL

Section III consists of Division 1, Division 2, and Division 3. These Divisions are broken down into Subsections and are designated by capital letters preceded by the letter "N" for Division 1, by the letter "C" for Division 2, and by the letter "W" for Division 3. The following eleven books make up the three Divisions.

Subsection NCA - General Requirements for Division 1 and Division 2

Division 1

Subsection NB - Class 1 Components

Subsection NC - Class 2 Components

Subsection ND - Class 3 Components

Subsection NE - Class MC Components

Subsection NF - Supports

Subsection NG - Core Support Structures

Subsection NH - Class 1 Components in Elevated Temperature Service

Appendices

Division 2 - Code for Concrete Reactor Vessels and Containments

Division 3 - Containment Systems and Transport Packagings for Spent Nuclear Fuel and High Level Radioactive Waste

The Division 2 book includes Subsection CC - Concrete Containments and Division 2 Appendices.

The Division 3 book includes Subsections WA and WB for General Requirements and Class TP (Type B) Containment, respectively.

2. SUBSECTIONS

Subsections are divided into Articles, Subarticles, paragraphs, and, where necessary, subparagraphs and subsubparagraphs.

3. ARTICLES

Articles are designated by the applicable letters indicated above for the Subsections followed by Arabic numbers, such as NB-1000. Where possible, Articles dealing with the same topics are given the same number in each Subsection in accordance with the following general scheme:

Article Number	Title
1000	Introduction or Scope
2000	Material
3000	Design
4000	Fabrication and Installation
5000	Examination
6000	Testing
7000	Overpressure Protection
8000	Nameplates, Stamping, and Reports

The numbering of Articles and the material contained in the Articles may not, however, be consecutive. Due to the fact that the complete outline may cover phases not applicable to a particular Subsection or Article, the rules have been prepared with some gaps in the numbering.

4. SUBARTICLES

Subarticles are numbered in units of 100, such as NB-1100.

5. SUBSUBARTICLES

Subsubarticles are numbered in units of 10, such as NB-2130, and generally have no text. When a number such as NB-1110 is followed by text, it is considered a paragraph.

6. PARAGRAPHS

Paragraphs are numbered in units of 1, such as NB-2121.

7. SUBPARAGRAPHS

Subparagraphs, when they are *major* subdivisions of a paragraph, are designated by adding a decimal followed by one or more digits to the paragraph number, such as NB-1132.1. When they are *minor* subdivisions of a paragraph, subparagraphs may be designated by lowercase letters in parentheses, such as NB-2121(a).

8. SUBSUBPARAGRAPHS

Subsubparagraphs are designated by adding lowercase letters in parentheses to the *major* subparagraph numbers, such as NB-1132.1(a). When further subdivisions of *minor* subparagraphs are necessary, subsubparagraphs are designated by adding Arabic numerals in parentheses to the subparagraph designation, such as NB-2121(a)(1).

9. REFERENCES

References used within Section III generally fall into one of the following four categories.

A. References to Other Portions of Section III

When a reference is made to another Article, Subarticle, or paragraph, all numbers subsidiary to that reference shall be included. For example, reference to NB-3000 includes all material in Article NB-3000; reference to NB-3200 includes all material in Subarticle NB-3200; reference to NB-3230 includes all paragraphs NB-3231 through NB-3236.

B. References to Other Sections

Other Sections referred to in Section III are:

Section II, Materials. When a requirement for a material, or for the examination or testing of a material, is to be in accordance with a specification such as SA-105, SA-370, or SB-160, the reference is to material specifications in Section II. These references begin with the letter "S."

Section V, Nondestructive Examination. Section V references begin with the letter "T" and relate to the nondestructive examination of material or welds.

Section IX, Welding and Brazing Qualifications. Section IX references begin with the letter "Q" and relate to welding and brazing requirements.

Section XI, Rules for Inservice Inspection of Nuclear Power Plant Components. When a reference is made to inservice inspection, the rules of Section XI shall apply.

C. Reference to Specifications and Standards Other Than Published in Code Sections

(1) Specifications for examination methods and acceptance standards to be used in connection with them are published by the American Society for Testing and Materials. At the time of publication of Section III, some such specifications were not included in Section II of this Code. A reference to ASTM E71-64 refers to the specification so designated by and published by ASTM, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

2 The American National Standards Institute (ANSI) was formerly known as the American Standard Association. Standards approved by the Association were designated by the prefix "ASA" followed by the number of the standard and the year of publication. More recently, the American Standards Institute was known as the United States of America Standard Institute. Standards were designated by the prefix "USAS" followed by the number of the standard and the year of publication. While the letters of the prefix have changed with the name of the organization, the numbers of the standard have remained unchanged.

(2) Dimensional standards covering products such as valves, flanges, and fittings are sponsored and published by the American Society of Mechanical Engineers and approved by the American National Standards Institute². When a product is to conform to such a standard, for example ANSI B16.5, the standard is approved by the American National Standards Institute. The applicable year of issue is that suffixed to its numerical designation in Table NB-3132-1, for example ANSI B16.5-1977. Standards published by the American Society of Mechanical Engineers are available from ASME, 22 Law Drive, Box 2300, Fairfield, NJ 07007-2300.

(3) Dimensional and other types of standards covering products such as valves, flanges, and fittings are also published by the Manufacturers Standardization Society of the Valve and Fittings Industry and are known as Standard Practices. When a product is required by these rules to conform to a Standard Practice, for example MSS SP-6, the Standard Practice referred to is published by the Manufacturers Standardization Society of the Valve and Fittings Industry, 127 Park Street, N.E., Vienna, VA 22180. The applicable year of issue of such a Standard Practice is that suffixed to its numerical designation in Table NB-3132-1, for example MSS SP-6-1963.

(4) Specifications for welding and brazing materials are published by the American Welding Society, 550 N.W. LeJeune Road, Miami, FL 33135. Specifications of this type are incorporated in Section II and are identified by the AWS designation with the prefix "SF," for example SFA-5.1.

(5) Standards applicable to the design and construction of tanks and flanges are published by the American Petroleum Institute and have designations such as API-620 and API-2000. When documents so designated are referred to in Section III,

they are standards published by the American Petroleum Institute.

D. References to Appendices

Two types of Appendices are used in Section III and are designated Mandatory and Nonmandatory.

(1) Mandatory Appendices contain requirements which must be followed in construction; such references are designated by a Roman numeral followed by Arabic numerals. References to II-1100 or XI-3212, for example, relate to the Mandatory Appendices.

(2) Nonmandatory Appendices provide information or guidance for the use of Section III; such references are designated by a capital letter followed by Arabic numerals. A reference to D-1100, for example, relates to a Nonmandatory Appendix.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NE-1000

ARTICLE NE-1000 INTRODUCTION

Page 1

NE-1100 SCOPE AND GENERAL REQUIREMENTS

NE-1110 ASPECTS OF CONSTRUCTION COVERED BY THESE RULES

Subsection NE establishes rules for material, design, fabrication, examination, inspection, testing, and preparation of reports for metal containment vessels.

NE-1120 RULES FOR CLASS MC CONTAINMENT VESSELS

(a) Class MC containment vessels shall be constructed in accordance with the rules of this Subsection, except as provided in NCA-2134(c). Only containment vessels and their appurtenances shall be classified as Class MC. Piping, pumps, and valves which are part of the containment system (NE-1130) or which penetrate or are attached to the containment vessel shall be classified as Class 1 or Class 2 by the Design Specification and meet the requirements of the applicable Subsection. Figure NE-1120-1 shows some typical penetrations with different Class designations.

(b) Subsection NE does not contain rules to cover all details of construction of Class MC containment vessels. The Certificate Holder shall provide details of construction which will be consistent with those provided by the rules of this Subsection. These details of construction shall be subject to the approval of the Owner or his designee, and acceptance by the Inspector.

NE-1130 BOUNDARIES OF JURISDICTION

The containment system includes (a) through (c) as follows:

(a) the containment vessel;

(b) all penetration assemblies or appurtenances attached to the containment vessel;

(c) all piping, pumps, and valves attached to the containment vessel, or to penetration assemblies out to and including any valves required to isolate the system and provide a pressure boundary for the containment function. Classification of such items shall be given in the Design Specifications (NCA-3250 and NE-1120).

NE-1131 Boundaries of the Containment Vessel

The Design Specification shall define the boundary of a containment vessel to which piping or another component is attached. Figure NE-1132-1 shows typical jurisdictional boundaries. The boundary shall not be closer to the containment vessel than:

- (a) the first circumferential joint in welded connections (the connecting weld shall be considered part of the piping);
- (b) the face of the first flange in bolted connections (the bolts shall be considered part of the piping);
- (c) the first threaded joint in screwed connections.

NE-1132 Boundary Between Containment Vessel and Attachments

NE-1132.1 Attachments

- (a) An attachment is an element, in contact with or connected to the inside or outside of the pressure retaining portion of a containment vessel, which may have either a pressure retaining or nonpressure-retaining function and either a structural or nonstructural function.
- (b) Attachments with a pressure retaining function include items such as stiffeners and vessel opening reinforcement.
- (c) Attachments with a nonpressure-retaining function include items such as thermal sleeves, turning vanes, and containment vessel support load path items such as vessel saddles, support and shear lugs, brackets, and skirts.
- (d) Attachments with a structural function (structural attachments) perform a pressure retaining function or are in the containment vessel support load path.

Page 4

- (e) Attachments with a nonstructural function (nonstructural attachments) do not perform a pressure retaining function, nor are they in the containment vessel support load path. Nonstructural attachments include items such as nameplates, insulation supports, and locating and lifting lugs.

[98]

NE-1132.2 Jurisdictional Boundary.

The jurisdictional boundary between the containment vessel and an attachment defined in the Design Specification shall not be any closer to the pressure retaining portion of the vessel than as defined in (a) through (g) below. Figures NE-1132.2-1, NE-1132.2-2, and NE-1132.2-3 are provided as an aid in defining the boundary and construction requirements of this Subsection.

- (a) Attachments cast or forged with the containment vessel and weld buildup on the vessel surface shall be considered part of the containment vessel.
- (b) Attachments, welds, and fasteners having a pressure retaining function shall be considered part of the containment vessel.
- (c) Except as provided in (d) and (e) below, the boundary between the containment vessel and an attachment not having a pressure retaining function shall be at the surface of the vessel.
- (d) The first connecting weld of a nonpressure-retaining structural attachment to the containment vessel shall be considered part of the vessel unless the weld is more than $2t$ from the pressure retaining portion of the vessel, where t is the nominal thickness of the pressure retaining material. Beyond $2t$ from the pressure retaining portion of the vessel, the first weld shall be considered part of the attachment.
- (e) The first connecting weld of a welded nonstructural attachment to the containment vessel shall be considered part of the attachment. At or within $2t$ from the pressure retaining portion of the component the first connecting weld shall conform to NE-4430.
- (f) Mechanical fasteners used to connect a nonpressure-retaining attachment to the containment vessel shall be considered part of the attachment.
- (g) The boundary may be located further from the pressure retaining portion of the containment vessel than as defined in (a) through (f) above when specified in the Design Specification.

[98]

FIG. NE-1120-1 TYPICAL CONTAINMENT PENETRATIONS

FIG. NE-1120-1 TYPICAL CONTAINMENT PENETRATIONS

FIG. NE-1132-1 SOME TYPICAL JURISDICTIONAL BOUNDARIES FOR WELDED CONNECTIONS CLASS MC CONTAINMENT VESSELS

FIG. NE-1132-1 SOME TYPICAL JURISDICTIONAL BOUNDARIES FOR WELDED CONNECTIONS CLASS MC CONTAINMENT VESSELS

- ① Containment vessel shall conform to Subsection NE.
- ② Pressure retaining portion of the containment vessel.
- ③ Jurisdictional boundary (heavy line).
- ④ Cast or forged attachment or weld buildup shall conform to Subsection NE.
- ⑤ Beyond $2t$ from the pressure retaining portion of the containment vessel, the design rules of NF-3000 may be used as a substitute for the design rules of NE-3000.
- ⑥ At or within $2t$ from the pressure retaining portion of the containment vessel, the first connecting weld shall conform to Subsection NE.
- ⑦ Beyond $2t$ from the pressure retaining portion of the containment vessel or beyond the first connecting weld, the attachment shall conform to Subsection NF [Note (1)].
- ⑧ Bearing, clamped, or fastened attachment shall conform to Subsection NF [Note (1)].
- ⑨ Attachment connection shall conform to Subsection NF [Note (1)].
- ⑩ At or within $2t$ from the pressure retaining portion of the containment vessel, the interaction effects of the attachment shall be considered in accordance with NE-3135.
- ⑪ Drilled holes shall conform to Subsection NE.

GENERAL NOTE:

These sketches are intended to show jurisdictional concepts and should not be considered as recommended configurations.

NOTE:

- (1) If the attachment is an intervening element [NF-1110(c)], material, design, and connections, as appropriate, are outside Code jurisdiction.

FIG. NE-1132.2-1 ATTACHMENTS IN THE CONTAINMENT VESSEL SUPPORT LOAD PATH WHICH DO NOT PERFORM A PRESSURE RETAINING FUNCTION

FIG. NE-1132.2-1 ATTACHMENTS IN THE CONTAINMENT VESSEL SUPPORT LOAD PATH WHICH DO NOT PERFORM A PRESSURE RETAINING FUNCTION

- ① Containment vessel shall conform to Subsection NE.
- ② Pressure retaining portion of the containment vessel.
- ③ Jurisdictional boundary (heavy line).
- ④ Cast or forged attachment or weld buildup shall conform to Subsection NE.
- ⑤ At or within $2t$ from the pressure retaining portion of the containment vessel, the material of the first welded nonstructural attachment shall conform to NE-2190; design is outside Code jurisdiction.
- ⑥ At or within $2t$ from the pressure retaining portion of the containment vessel, the first connecting weld shall conform to NE-4430.
- ⑦ Beyond $2t$ from the pressure retaining portion of the containment vessel, the nonstructural attachment is outside Code jurisdiction.
- ⑧ Bearing, clamped, or fastened nonstructural attachment is outside Code jurisdiction.
- ⑨ Nonstructural attachment connection is outside Code jurisdiction.
- ⑩ At or within $2t$ from the pressure retaining portion of the containment vessel, the interaction effects of the nonstructural attachment shall be considered in accordance with NE-3135.
- ⑪ Drilled holes shall conform to Subsection NE.

GENERAL NOTE:

These sketches are intended to show jurisdictional concepts and should not be considered as recommended configurations.

FIG. NE-1132.2-2 ATTACHMENTS WHICH DO NOT PERFORM A PRESSURE RETAINING FUNCTION AND ARE NOT IN THE CONTAINMENT VESSEL SUPPORT LOAD PATH (NONSTRUCTURAL ATTACHMENTS)

FIG. NE-1132.2-2 ATTACHMENTS WHICH DO NOT PERFORM A PRESSURE RETAINING FUNCTION AND ARE NOT IN THE CONTAINMENT VESSEL SUPPORT LOAD PATH (NONSTRUCTURAL ATTACHMENTS)

- ① Containment vessel shall conform to Subsection NE.
- ② Pressure retaining portion of the containment vessel.
- ③ Jurisdictional boundary (heavy line).
- ④ Cast or forged attachment or weld buildup shall conform to Subsection NE.
- ⑤ Welded attachment shall conform to Subsection NE.
- ⑥ Bearing, clamped, or fastened attachment shall conform to Subsection NE.
- ⑦ Attachment connection shall conform to Subsection NE.
- ⑧ Drilled holes shall conform to Subsection NE.

GENERAL NOTE:

These sketches are intended to show jurisdictional concepts and should not be considered as recommended configurations.

PRESSURE RETAINING FUNCTION**

FIG. NE-1132.2-3 ATTACHMENTS WHICH PERFORM A PRESSURE RETAINING FUNCTION

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NE-2000

ARTICLE NE-2000 MATERIAL

NE-2100 GENERAL REQUIREMENTS FOR MATERIAL

NE-2110 SCOPE OF PRINCIPAL TERMS EMPLOYED

(a) The term *material* as used in this Subsection is defined in NCA-1220. The term *Material Organization* is defined in NCA-9000.

(b) The term *pressure retaining material* as used in this Subsection applies to items such as vessel shells, heads, and nozzles; pipes, tubes, and fittings; and bolting which joins pressure retaining items.

(c) The requirements of this Article make reference to the term *thickness*. For the purpose intended, the following definitions of nominal thickness apply:

(1) *plate* - the thickness is the dimension of the short transverse direction

(2) *forgings* - the thickness is the dimension defined as follows:

(a) *hollow forgings* - the nominal thickness is measured between the inside and outside surfaces (radial thickness)

(b) *disk forgings* (axial length less than the outside diameter) - the nominal thickness is the axial length

(c) *flat ring forgings* (axial length less than the radial thickness) - for axial length > 2 in. (51 mm), the axial length is the nominal thickness. For axial length > 2 in. (51 mm), the radial thickness is the nominal thickness.

(d) *rectangular solid forgings* - the least rectangular dimension is the nominal thickness

(3) *castings*

(a) Thickness *t* for fracture toughness testing is defined as the nominal pipe wall thickness of the connecting piping.

(b) Thickness *t* for heat treatment purposes is defined as the thickness of the pressure retaining wall of the casting, excluding flanges and sections designated by the designer as nonpressure retaining.

NE-2120 PRESSURE RETAINING MATERIAL

NE-2121 Permitted Material Specifications

(a) Pressure retaining material shall conform to the requirements of one of the specifications for materials given in Table NE-2121(a)-1 and Table NE-2121(a)-2 and to all of the requirements of this Article which apply to the product form in which the material is used. Attachments which perform a pressure retaining function shall be pressure retaining material.

(b) The requirements of this Article do not apply to material for items not associated with the pressure retaining function of a component, such as shafts, stems, trim, spray nozzles, bearings, bushings, springs, and wear plates, nor to seals, packing, gaskets, valve seats, and ceramic insulating material and special alloys used as seal material in electrical penetration assemblies.

(c) Pressure retaining material of ferritic steel whose thickness exceeds $\frac{1}{4}$ in. (6 mm) for containment vessels shall be normalized or quenched and tempered, fully killed, and melted to a fine grain melting practice, whenever the material is not impact tested (NE-2311).

(d) Welding and brazing materials used in manufacture of items shall comply with an SFA Specification in Section II, Part C, except as otherwise permitted in Section IX, and shall also comply with the applicable requirements of this Article. The requirements of this Article do not apply to materials used as backing rings or backing strips in welded joints.

(e) The requirements of this Article do not apply to hard surfacing or corrosion resistant weld metal overlay which is 10% or less of the thickness of the base material (NE-3122).

TABLE NE-2121-(a)-1 (CONT'D) MATERIAL SPECIFICATIONS AND GRADES PERMITTED FOR CLASS MC CONSTRUCTION

wherever these special requirements conflict with the material specification requirements [NCA-3856]. Where the special requirements include an examination, test, or treatment which is also required by the material specification, the examination, test, or treatment need be performed only once. Required nondestructive examinations shall be performed as specified for each product form in NE-2500. Any examination, repair, test, or treatment may be performed by the Material Organization or Certificate Holder as provided in NE-4121.1. Any hydrostatic or pneumatic pressure test required by a material specification need not be performed, provided the material is identified as not having been pressure tested and it is subsequently pressure tested, except where the location of the material in the vessel or the installation would prevent performing any nondestructive examination required by the material specification to be performed subsequent to the hydro static or pneumatic test.

TABLE NE-2121(a)-2 PERMITTED BOLTING MATERIAL SPECIFICATIONS

Low Alloy Steels

SA-193 Grade B7, B16

SA-320 Grade L43

High Alloy Steels

SA-193 Grade B6 Class 410

SA-193 Grade B8, B8C, B8T, B8M

SA-437 Grade B4B, B4C

SA-453 Grade 651, 610

TABLE NE-2121(a)-2 PERMITTED BOLTING MATERIAL SPECIFICATIONS

NE-2124 Material Size Ranges and Tolerances

(a) Material outside the limits of size or thickness given in any specification in Section II may be used if the material is in compliance with the other requirements of the specification and no size limitation is given in this Subsection. In those specifications in which chemical composition or mechanical properties are indicated to vary with size or thickness, any material outside the specification range shall be required to

Page 20

conform to the composition and mechanical properties shown for the nearest specified range [NCA-3856].

(b) Plate material shall be ordered not thinner than the design thickness. Vessels, except for piping, made of plate furnished with an under tolerance of not more than the lesser value of 0.01 in. (0.3 mm) or 6% of the ordered thickness may be used at the full design pressure for the thickness ordered. If the specification to which the plate is ordered allows a greater under tolerance, the ordered thickness of the material shall be sufficiently greater than the design thickness so that the thickness of the material furnished is not more than the lesser of 0.01 in. (0.3 mm) or 6% under the design thickness.

(c) If pipe or tube is ordered by its nominal wall thickness, the manufacturing under tolerance on wall thickness shall be taken into account. The manufacturing under tolerances are given in the several pipe and tube specifications listed in Table NE-2121(a)-1. After the minimum wall thickness is determined, it shall be increased by an amount sufficient to provide for the manufacturing under tolerance allowed in the pipe or tube specification.

NE-2125 Materials in Combination¹

A vessel may be designed and constructed of any combination of materials permitted in NE-2000 provided the applicable rules are followed and the requirements of Section IX for welding dissimilar metals are met.

¹ Because of the different thermal coefficients of expansion of dissimilar material, caution should be exercised in design and construction under the provisions of this paragraph in order to avoid

NE-2126 Condition of Material for Intended Service

Specific chemical compositions, heat treatment procedures, fabrication requirements, and supplementary tests may be required to ensure that the component will be in its most favorable condition for the intended service. This is particularly true for components subject to severe corrosion. These rules do not indicate the selection of material suitable for the intended service or the amount of corrosion allowance to be provided. It is recommended that Owners assure themselves, by appropriate tests or other means, that the material selected and its heat treatment during fabrication will be suitable for the intended service with respect both to corrosion resistance and to retention of satisfactory mechanical properties during the desired service life.

NE-2127 Clad Plate

(a) Clad plate used in constructions in which the design calculations are based on the total thickness, including cladding, shall conform to one of the following specifications:

- (1) SA-263 Corrosion-Resisting Chromium Steel Clad Plate, Sheet, and Strip;
- (2) SA-264 Stainless Chromium-Nickel Steel Clad Plate, Sheet, and Strip;
- (3) SA-265 Nickel and Nickel-Base Alloy Clad Steel Plate.

(b) Clad plate used in constructions in which the design calculations are based on the clad plate thickness, exclusive of the thickness of the cladding material, may consist of any base plate material satisfying the requirements of NE-2121 and any metallic cladding material of weldable quality that in the judgment of the Owner is suitable for the intended service.

(c) Integrally clad steel plate in which any part of the cladding is included in the design calculations, as permitted in NE-3122.4(b), shall show a minimum shear strength of 20.0 ksi when tested in the manner described in the plate specification. One shear test shall be made on each such clad plate as rolled and the results shall be reported by the mill.

(d) When any part of the cladding thickness is specified as an allowance for corrosion, such added thickness shall be removed before mill tension tests are made. When corrosion of the cladding is not expected, no part of the cladding material need be removed before testing, even though excess thickness seems to have been provided or is available as corrosion allowance.

NE-2128 Bolting Material

(a) Material for nuts shall conform to SA-194 or to the requirements for nuts in the specification for the bolting material which is to be used.

(b) Nuts shall be threaded to Class 2B or finer tolerances according to ANSI B1.1. Materials for nuts and washers shall be selected as follows.

- (1) Carbon steel nuts and carbon steel washers may be used with carbon steel bolts or studs.
- (2) Carbon or alloy steel nuts and carbon or alloy steel washers of approximately the same hardness as the nuts may be used with alloy steel bolts or studs for metal temperatures not exceeding 900°F (482°C).
- (3) Alloy steel nuts shall be used with alloy steel studs or bolts for metal temperatures exceeding 900°F

Page 21

(482°C). Washers, if used, shall be of alloy steel with equivalent chemistry and hardness to the nut material.

(c) Nuts shall be semifinished, chamfered, and trimmed. For use with flanges conforming to the standards listed in NE-3362, nuts shall conform at least to the dimensions given in ANSI B18.2 for Heavy Series Nuts. For use with connections designed in accordance with the rules in Appendix XI, nuts may be of the ANSI Standard Heavy Series or they may be of other dimensions, provided their strength is equal to that of the bolting, giving due consideration to bolt hole clearance, bearing area, thread form and class off it, thread shear, and radial thrust from threads.

NE-2130 CERTIFICATION OF MATERIAL

All material used in the construction of Class MC containment vessels shall be certified as required in NCA-3862 and NCA-3861. Certified Material Test Reports are required for pressure retaining material except as provided by NCA-3861. A Certificate of Compliance may be provided in lieu of Certified Material Test Reports for all other material. Copies of all Certified Material Test Reports and Certificates of Compliance applicable to material used in a vessel shall be furnished with the material.

NE-2140 WELDING MATERIAL

For the requirements governing the material to be used for welding, see NE-2400.

NE-2150 MATERIAL IDENTIFICATION

The identification of pressure retaining material shall meet the requirements of NCA-3856. Material for small items shall be controlled during manufacture of the vessel so that they are identifiable as acceptable material at all times. Welding and brazing material shall be controlled during the repair of material and the manufacture of vessels so that they are identifiable as acceptable until the material is actually consumed in the process(NE-4122).

NE-2160 DETERIORATION OF MATERIAL IN SERVICE

Consideration of deterioration of material caused by service is generally outside the scope of this Subsection. It is the responsibility of the Owner to select material suitable for the conditions stated in the Design Specifications (NCA-3250), with specific attention being given to the effects of service conditions upon the properties of the material.

NE-2170 HEAT TREATMENT TO ENHANCE IMPACT PROPERTIES

Carbon steels, low alloy steels, and high alloy chromium (Series 4XX) steels may be heat treated by quenching and tempering to enhance their impact properties. Postweld heat treatment of the material at a temperature of not less than 1100°F (593°C) may be considered to be the tempering phase of the heat treatment. The requirements of NE-2220 shall be met.

NE-2180 PROCEDURES FOR HEAT TREATMENT OF MATERIAL

When heat treating temperature or time is required by the material specification and the rules of this Subsection, the heat treating shall be performed in temperature-surveyed and -calibrated furnaces or the heat treating shall be controlled by measurement of material temperature by thermocouples in contact with the material or attached to blocks in contact with the material, or by calibrated pyrometers instruments. Heat treating shall be performed under furnace loading conditions such that the heat treatment is in accordance with the material specification and the rules of this Subsection.

NE-2190 NONPRESSURE-RETAINING MATERIAL

(a) Material in the containment vessel support load path and not performing a pressure retaining function (see NE-1130) welded to pressure retaining material shall meet the requirements of NF-2000.

(b) Material not performing a pressure retaining function and not in the containment vessel support load path (nonstructural attachments) welded at or within $2t$ of the pressure retaining portion of the vessel need not comply with NE-2000 or NF-2000 provided the requirements of NE-4430 are met.

(c) Structural steel rolled shapes, which are permitted by this Subsection to be furnished with a Certificate of Compliance, may be repaired by welding using the welders, documentation, and examination requirements specified in SA-6.

Page 22

NE-2200 MATERIAL TEST COUPONS AND SPECIMENS FOR FERRITIC STEEL MATERIAL

NE-2210 HEAT TREATMENT REQUIREMENTS

NE-2211 Test Coupon Heat Treatment for Ferritic Material²

Where ferritic steel material is subjected to heat treatment during fabrication or installation of a containment vessel, the material used for the tensile and impact test specimens shall be heat treated in the same manner as the containment vessel, except that test coupons and specimens for P-No. 1 material with a nominal thickness of 2 in. (51 mm) or less are not required to be so heat treated. The Certificate Holder shall provide the Material Organization with the temperature and heating and cooling rate to be used. In the case of postweld heat treatment, the total time at temperature or temperatures for the test material shall be at least 80% of the total time at temperature or temperatures during actual postweld heat treatment of the material, and the total time at temperature or temperatures for the test material, coupon, or specimen may be performed in a single cycle.

NE-2212 Test Coupon Heat Treatment for Quenched and Tempered Material

[98]

NE-2212.1 Cooling Rates.

Where ferritic steel material is subjected to quenching from the austenitizing temperature, the test coupons representing those materials shall be cooled at a rate similar to and no faster than the main body of the material, except in the case of certain forgings and castings [NE-2223.3 and NE-2226(b)(5)]. This rule shall apply for coupons taken directly from the material as well as for separate test coupons representing the material, and one of the general procedures described in NE-2212.2 or one of the specific procedures described in NE-2220 shall be used for each product form.

[98]

2 Any Postweld heat treatment which is anticipated to be applied to the material or item after it is completed shall be specified in the Design Specification. The Certificate Holder shall include this time in the total time at temperature specified to be applied to the test specimens.

NE-2212.2 General Procedures.

One of the general procedures in (a), (b), and (c) below may be applied to quenched and tempered material or test coupons representing the material, provided the specimens are taken relative to the surface of the product in accordance with NE-2220. Further specific details of the methods to be used shall be the obligation of the Material Organization and the Certificate Holder.

(a) Any procedure may be used which can be demonstrated to produce a cooling rate in the test material that matches the cooling rate of the main body of the product at the region midway between midthickness and the surface ($1/4t$) and no nearer any heat treated edge than a distance equal to the nominal thickness t being quenched within 25°F (14°C) and 20 sec at all temperatures after cooling begins from the austenitizing temperature.

(b) If cooling rate data for the material and cooling rate control devices for the test specimens are available, the test specimens may be heat treated in the device to represent the material, provided that the provisions of (a) above are met.

(c) When any of the specific procedures described in NE-2220 are used, faster cooling rates at the edges may be compensated for by:

- (1) taking the test specimens at least t from a quenched edge, where t equals the material thickness;
- (2) attaching a steel pad at least t wide by a partial penetration weld (which completely seals the buffered surface) to the edge where specimens are to be removed; or
- (3) using thermal barriers or insulation at the edge where specimens are to be removed.

It shall be demonstrated (and this information shall be included in the Certified Material Test Report) that the cooling rates are equivalent to (a) or (b) above.

NE-2220 PROCEDURE FOR OBTAINING TEST COUPONS AND SPECIMENS FOR QUENCHED AND TEMPERED MATERIAL

NE-2221 General Requirements

The procedure for obtaining test specimens for quenched and tempered material is related to the product form. Coupon and specimen location shall be as required by the material specification, except as stated in the following paragraphs of this Subarticle. References to dimensions signify nominal values.

NE-2222 Plates

NE-2222.1 Orientation and Location of Coupons.

Coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from a rolled surface and with the midlength of the specimen at least t from

Page 23

any heat treated edge, where t is the nominal thickness of the material.

NE-2222.2 Requirements for Separate Test Coupons.

Where a separate test coupon is used to represent the component material, it shall be of sufficient size to ensure that the cooling rate of the region from which the test coupons are removed represents the cooling rate of the material at least $\frac{1}{4}t$ deep and t from any edge of the product. Unless cooling rates applicable to the bulk pieces or product are simulated in accordance with NE-2212.2, the dimensions of the coupon shall be not less than $3t \times 3t \times t$, where t is the nominal material thickness.

NE-2223 Forgings

NE-2223.1 Location of Coupons.

Coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from any surface and with the midlength of the specimens at least t from any second surface, where t is the maximum heat treated thickness. A thermal buffer as described in NE-2212.2(c) may be used to achieve these conditions, unless cooling rates applicable to the bulk forgings are simulated as other wise provided in NE-2212.2.

NE-2223.2 Very Thick and Complex Forgings.

Test coupons for forgings which are both very thick and complex, such as contour nozzles, thick tubesheets, flanges, nozzles, and other complex forgings that are contour shaped or machined to essentially the finished product configuration prior to heat treatment, may be removed from prolongations or other stock provided on the product. The Certificate Holder shall specify the surfaces of the finished product subjected to high tensile stresses in service. The coupons shall be taken so that specimens shall have their longitudinal axes at a distance below the nearest heat treated surface, equivalent to at least the greatest distance that the indicated high tensile stress surface will be from the nearest surface during heat treatment, and with the midlength of the specimens a minimum of twice this distance from a second heat treated surface. In any case, the longitudinal axes of the specimens shall not be nearer than $\frac{3}{4}$ in. (19 mm) to any heat treated surface and the midlength of the specimens shall be at least $1\frac{1}{2}$ in. (38 mm) from any heat treated surface.

NE-2223.3 Coupons From Separately Produced Test Forgings.

Test coupons representing forgings from one heat and one heat treatment lot may be taken from a separately forged piece under the conditions given in (a) through (e) below.

(a) The separate test forging shall be of the same heat of material and shall be subjected to substantially the same reduction and working as the production forging it represents.

(b) The separate test forging shall be heat treated in the same furnace charge and under the same conditions as the production forging.

(c) The separate test forging shall be of the same nominal thickness as the production forging.

(d) Test coupons for simple forgings shall be taken so that specimens shall have their longitudinal axes at the region

midway between midthickness and the surface and with the midlength of the specimens no nearer any heat treated edge than a distance equal to the forging thickness, except when the thickness-length ratio of the production forging does not permit, in which case a production forging shall be used as the test forging and the midlength of the specimens shall be at the midlength of the test forging.

(e) Test coupons for complex forgings shall be taken in accordance with NE-2223.2.

NE-2223.4 Test Specimens for Forgings.

When test specimens for forgings are to be taken under the applicable specification, the Inspector shall have the option of witnessing the selection, placing an identifying stamp on them, and witnessing the testing of these specimens.

NE-2224 Location of Coupons

(a) *Bars.* Coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from the outside or rolled surface, and with the midlength of the specimens at least t from a heat treated end where t is either the bar diameter or thickness.

(b) *Bolting Material.* For bolting material, the coupons shall be taken in conformance with the applicable material specification and with the midlength of the specimen at least one diameter or thickness from a heat treated end. When the studs, nuts, or bolts are not of sufficient length, the midlength of the specimen shall be at the midlength of the studs, nuts, or bolts. The studs, nuts, or bolts selected to provide test coupon material shall be identical with respect to the quenched contour and size except for length, which shall equal or exceed the length of the represented studs, nuts, or bolts.

NE-2225 Tubular Products and Fittings

NE-2225.1 Location of Coupons.

Coupons shall be taken so that specimens shall have their longitudinal

Page 24

axes at least $\frac{1}{4}t$ from the inside or outside surface and with the midlength of the specimens at least t from a heat treated end where t is the nominal wall thickness of the tubular product.

NE-2225.2 Separately Produced Coupons Representing Fittings.

Separately produced test coupons representing fittings may be used. When separately produced coupons are used, the requirements of NE-2223.3 shall be met.

NE-2226 Tensile Test Specimen Location (for Quenched and Tempered Ferritic Steel Castings)

NOTE: Users of this requirement should note that the hardenability of some grades may limit the usable section size.

(a) This section applies only to quenched and tempered ferritic steel castings with a thickness t exceeding 2 in. (51 mm), where t is the thickness of the pressure retaining wall of the casting, excluding flanges and sections designated by the designer as nonpressure retaining. The order, inquiry, and drawing shall designate what the thickness t is for the casting.

(b) One of the following shall apply.

(1) The longitudinal centering of the thickness of the tension test specimen shall be taken at least $\frac{1}{4}t$ from the t dimension surface. For cylindrical castings, the longitudinal center line of the specimens shall be taken at least $\frac{1}{4}t$ from the outside or inside surface and the gage length at least t from the as-heat-treated end.

(2) Where separately cast test coupons are used, their dimensions shall be not less than $3t \times 3t \times t$ and each specimen cut from it shall meet the requirements of (b). The test coupon shall be of the same heat of steel and shall receive substantially the same casting practices as the production casting it represents. (Centrifugal castings may be represented by statically cast coupons.) The test coupon shall be heat treated under the same conditions as the production casting(s). The t dimension of the test coupon shall be the same maximum thickness t as defined in (a) above. Where separate test blocks require reheat treatment, thermal buffers in accordance with (b) may be used.

(3) Where specimens are to be removed from the body of the casting, a steel, thermal buffer pad $1t \times 1t \times$ at least $3t$ shall be joined to the casting surface by a partial penetration weld completely sealing the buffered surface prior to the heat treatment process. The test specimens shall be removed from the casting in a location adjacent to the center third of the buffer pad. They shall be located at a minimum distance of $\frac{1}{2}$ in. from the buffered surface and $\frac{1}{4}$ from the other heat treated surfaces.

(4) Where specimens are to be removed from the body of the casting, thermal insulation or other thermal barriers shall be used during the heat treatment process adjacent to the casting edge where specimens are to be removed. It shall be demonstrated that the cooling rate of the test specimen is no faster than that of specimens taken by the method described in (b)(1) above. This information shall be included in the test reports.

(5) Where castings are cast or machined to essentially the finished product configuration prior to heat treatment, the test specimens shall be removed from a casting prolongation or other stock on the product at a location below the nearest heat treated surface indicated on the order. The specimens shall be located with their longitudinal axes a distance below the nearest heat treated surface equivalent to at least the greatest distance that the indicated high tensile stress surface will be from the nearest heat treated surface and with their midlength a minimum of twice this distance from a second heat treated surface. In any case, the longitudinal axes of the test specimens shall be no nearer than $\frac{1}{4}$ in. (6 mm) to a heat treated surface and the midlength shall be at least $1\frac{1}{2}$ in. (38 mm) from a second heat treated surface. The component manufacturer shall specify the surfaces of the finished product subjected to high tensile stress in service.

NE-2300 FRACTURE TOUGHNESS REQUIREMENTS FOR MATERIAL

NE-2310 MATERIAL TO BE IMPACT TESTED

NE-2311 Material for Which Impact Testing Is Required

(a) Pressure retaining material shall be impact tested in accordance with the requirements of NE-2330, except that impact testing of materials described in (1) through (9) below is not a requirement of this Subsection, provided the requirements of NE-2121(c) are met.

(1) material with a nominal section thickness of $\frac{5}{8}$ in. (16 mm) or less where the thickness shall be taken as defined in (a) through (d) below:

(a) for vessels, use the nominal thickness of the shell or head, as applicable;

(b) for nozzles or parts welded to vessels, use the lesser of the vessel shell thickness to which the

Page 25

item is welded or the maximum radial thickness of the item exclusive of integral shell butt welding projections;

**TABLE NE-2311(a)-1
EXEMPTIONS FROM IMPACT TESTING UNDER
NE-2311(a)(8)**

Material [Note (1)]	Material Condition [Note (2)]	T_{NDT} , [Notes (3), (4)] °F
SA-537 Class 1	N	-30
SA-516 Grade 70	Q&T	-10
SA-516 Grade 70	N	0
SA-508 Class 1	Q&T	+10
SA-299 [Note (5)]	N	+20
SA-216 Grades WCB, WCC	Q&T	+30

NOTES:

- (1) These materials are exempt from toughness testing when LST — T_{NDT} is satisfied in accordance with the rules established in Appendix R.
- (2) Material Condition letters refer to:
N — Normalize
Q&T — Quench and Temper
- (3) These values for T_{NDT} were established from data on heavy section steel (thickness greater than 2½ in.). Values for sections less than 2½ in. thick are held constant until additional data are obtained.
- (4) T_{NDT} — temperature at or above nil-ductility transition temperature NDT (ASTM E 208-91); T_{NDT} is 10°F below the temperature at which at least two specimens show no-break performance.
- (5) Materials made to a fine grain melting practice.

TABLE NE-2311(a)-1 EXEMPTIONS FROM IMPACT TESTING UNDER NE-2311(a)(8)

(c) for flat heads, tubesheets, or flanges, use the maximum shell thickness associated with the butt welding hub;

(d) for integral fittings used to attach process piping to the containment vessel (Fig. NE-1120-1), use the larger nominal thickness of the pipe connections;

- (2) bolting, including studs, nuts, and bolts with a nominal size of 1 in. (25 mm) or less;
- (3) bars with a nominal cross-sectional area which does not exceed 1 sq in. (645 mm²);
- (4) all thicknesses of material for pipe, tube, and fittings with a nominal pipe size 6 in. diameter (DN 150) and smaller;
- (5) material for fittings with pipe connections of $\frac{5}{8}$ in. (16 mm) nominal wall thickness and less;
- (6) austenitic stainless steels;
- (7) nonferrous materials;

³ T_{NDT} - temperature at or above the nil-ductility transition temperature NDT (ASTM E 208-91) T_{NDT} is 10°F below the temperature at which at least two specimens show no-break performance.

(8) materials listed in Table NE-2311(a)-1 for which the listed value of T_{NDT} ³ is lower than the Lowest Service Metal Temperature⁴ (LST) by an amount established by the rules in Appendix R. This exemption does not exempt either the weld metal (NE-2430) or the welding procedure qualification (NE-4335) from impact testing.

(9) materials for components for which the Lowest Service Temperature exceeds 150°F (66°C);

(b) The Design Specification shall state the Lowest Service Temperature for the component.

(c) Drop weight tests are not required for the martensitic high alloy chromium (Series 4XX) steels and precipitation-hardening steels listed in Section II, Part D, subpart 1, Table 1A. The other requirements of NE-2331 and NE-2332 apply for these steels. For nominal wall thicknesses greater than $2\frac{1}{2}$ in. (57 mm), the required C_v values shall be 40 mils (1.00 mm) lateral expansion.

NE-2320 IMPACT TEST PROCEDURES

NE-2321 Types of Tests

NE-2321.1 Drop Weight Tests.

The drop weight test, when required, shall be performed in accordance with ASTM E 208-91. Specimen types P-1, P-2, or P-3 may be used. When drop weight tests are performed to meet the requirements of NE-2300, the test temperature and the results shall be reported on the Certified Material Test Report.

NE-2321.2 Charpy V-Notch Tests.

The Charpy V-notch tests (C_v), when required, shall be performed in accordance with SA-370. Specimens shall be in accordance with SA-370, Fig. 11, Type A. A test shall consist of a set of three full-size 10 mm × 10 mm specimens. The lateral expansion and absorbed energy, as applicable, and the test temperature, as well as the orientation and location of all tests performed to meet the requirements of NE-2330 shall be reported in the Certified Material Test Report.

⁴ The Lowest Service Metal Temperature shall be the lowest temperature which the metal may experience in service while the plants is in operation and shall be established by appropriate calculations based on atmospheric ambient conditions, the insulation or enclosure provided, and the minimum temperature which will be maintained inside the vessel during the plant operation.

NE-2322 Test Specimens

NE-2322.1 Location of Test Specimens.

Impact test specimens shall be removed from a depth within the material that is at least as far from the material surface as that specified for tensile test specimens in the material

Page 26

specification. For bolting, the C_v impact test specimens shall be taken with the longitudinal axis of the specimen located at least one-half radius or 1 in. (25 mm) below the surface plus the machining allowance per side, whichever is less. The fracture plane of the specimen shall be at least one diameter or thickness from the heat treated end. When the studs, nuts, or bolts are not of sufficient length, the midlength of the specimen shall be at the midlength of the studs, nuts, or bolts. The studs, nuts, or bolts selected to provide test coupon material shall be identical with respect to the

quenched contour and size except for length, which shall equal or exceed the length of the represented studs, nuts, or bolts.

NE-2322.2 Orientation of Test Specimens

(a) Specimens for C_v impact tests for quenched and tempered material shall be oriented in accordance with the requirements of NE-2220 and for other material in accordance with the requirements given in SA-370.

(b) Specimens for drop weight tests may have their axes oriented in any direction.

NE-2330 TEST REQUIREMENTS AND ACCEPTANCE STANDARDS

NE-2331 Pressure Retaining Material Test Methods and Temperature

(a) Pressure retaining material shall be impact tested in accordance with one of the test methods indicated below.

(1) Charpy V-notch testing at or below the Lowest Service Metal Temperature.⁴⁵

(2) Drop weight testing to show that the Lowest Service Metal Temperature⁴ ($LST - T_{NDT}$) is satisfied in accordance with the rules established in Appendix R.

5 The requirements for impact testing of the heat affected zone (NE-4335.2) may result in reduced impact test temperatures for the base material.

6 The Lowest Overpressure Test Metal Temperature shall be the lowest temperature which the metal may experience during the overpressure test. It shall be established by appropriate calculations based on atmospheric conditions, the insulation or enclosure provided, and the temperature which will be maintained inside the vessel during the test.

(b) In addition, when the Design Specification requires a vessel hydrostatic or pneumatic test temperature which is lower than the Lowest Service Metal Temperature,⁴ the impact testing for pressure retaining material shall be performed in accordance with (a) above, at or below the lowest specified vessel test temperature. As an alternative, a Lowest Overpressure Test Metal Temperature⁶ shall be specified. In this case, Charpy

V-notch testing, in addition to the tests required by (a) above, shall be performed as specified in NE-2321.2 at a temperature 30°F (17°C) or more below the Lowest Overpressure Test Metal Temperature in accordance with NE-2333.

**TABLE NE-2332.1-1
REQUIRED C_v LATERAL EXPANSION VALUES
FOR PRESSURE RETAINING MATERIAL
OTHER THAN BOLTING**

Nominal Wall Thickness, in.	Lateral Expansion, mils [Notes (1) and (2)]	
	Average of 3	Lowest 1 of 3
$\frac{5}{8}$ in. or less [Note (3)]	...	...
Over $\frac{5}{8}$ in. to 1 in., incl.	20	15
Over 1 in. to $1\frac{1}{2}$ in., incl.	25	20
Over $1\frac{1}{2}$ in. to $2\frac{1}{2}$ in., incl.	35	30
Over $2\frac{1}{2}$ in. [Note (4)]	45	40

NOTES:

- (1) Where weld metal tests of NE-2400 are made to these requirements, the impact lateral expansion shall conform to the requirements of either of the base materials being joined.
- (2) Where two base materials having different required lateral expansion values are joined, the weld metal lateral expansion requirements of NE-4330 shall conform to the requirements of either of the base materials.
- (3) No test required.
- (4) For use with NE-2332.2(b).

TABLE NE-2332.1-1 REQUIRED C_v LATERAL EXPANSION VALUES FOR PRESSURE RETAINING MATERIAL
OTHER THAN BOLTING

(c) The use of the material below the temperature established by the methods of (a) or (b) above may be justified by methods equivalent to those contained in Appendix G.

NE-2332 Specific Test Methods and Acceptance Standards for Pressure Retaining Material for Tests Based on Lowest Service Metal Temperatures

NE-2332.1 Pressure Retaining Material Other Than Bolting With 2½ in. (64 mm) Maximum Thickness.

Except as limited in NE-4335, apply one of the methods of NE-2331(a) to test: the base material; the base material, the heat affected zone, and the weld metal for the weld procedure qualification tests of NE-4335; and the weld metal for NE-2431.

The impact test results shall meet one of the acceptance standards applicable to the specified test method.

(a) *Charpy V-Notch Testing for Lateral Expansion Values.* The test results of the three specimens, collectively and singly, shall meet the respective requirements of Table NE-2332.1-1.

Page 27

**TABLE NE-2332.1-2
REQUIRED C_v ENERGY VALUES¹ FOR PRESSURE RETAINING MATERIAL OTHER THAN BOLTING**

Nominal Wall Thickness, in.	Energy, ft-lb for Base Materials [Note (2)] of Specified Minimum Yield Strength, ksi					
	55 ksi or Below		Over 55 ksi to 75 ksi, Incl.		Over 75 ksi to 105 ksi, Incl.	
	Average of 3	Lowest 1 of 3	Average of 3	Lowest 1 of 3	Average of 3	Lowest 1 of 3
⅝ in. or less [Note (3)]	...	...	...	...	...	...
Over ⅝ in. to 1 in., incl.	20	15	25	20	30	25
Over 1 in. to 1½ in., incl.	25	20	30	25	35	30
Over 1½ in. to 2½ in., incl.	35	30	40	35	45	40
Over 2½ in. [Note (4)]	45	40	50	45	55	50

NOTES:

- (1) Where weld metal tests of NE-2400 are made to these requirements, the impact energy shall conform to the requirements of either of the base materials being joined.
- (2) Where two base materials having different required energy values are joined, the weld metal impact energy requirements of the procedure qualification tests of NE-4330 shall conform to the requirements of either of the base materials.
- (3) No test required.
- (4) For use with NE-2332.2(b).

TABLE NE-2332.1-2 REQUIRED C_v ENERGY VALUES¹ FOR PRESSURE RETAINING MATERIAL OTHER THAN BOLTING

(b) *Charpy V-Notch Testing for Absorbed Energy Values.* The test results of the three specimens, collectively and singly, shall meet the respective requirements of Table NE-2332.1-2.

(c) *Drop Weight Testing.* An acceptance test shall consist of at least two no-break specimens as described in ASTM E 208-91.

NE-2332.2 Pressure Retaining Material Other Than Bolting With Thickness Exceeding 2½ in. (64 mm)

(a) The base material and the weld procedure qualification weld metal tests of NE-4335 shall be tested by the drop weight method as specified in NE-2321.1 and NE-2331(a)(2).

(b) Except as limited in NE-4335, apply one of the methods of NE-2331(a) to test the base material and the heat affected zone of the weld procedure qualification tests for NE-4335 and the weld metal for NE-2431.

(c) The acceptance standards shall be as given in NE-2332.1(a), NE-2332.1(b), or NE-2332.1(c), as applicable.

NE-2332.3 Bolting Material.

The drop weight test is not applicable to bolting materials. For bolting material, including nuts, studs, and bolts, a Charpy V-notch test shall be performed. Optionally, the test may be performed at the Lowest Service Metal Temperature, or at a temperature 30°F (17°C) or more below the Lowest Service Metal Temperature.

(a) When tested at the Lowest Service Metal Temperature, lateral expansion and absorbed energy values shall be determined, and all three specimens shall meet the requirements of Table NE-2332.3(a)-1.

**TABLE NE-2332.3(a)-1
REQUIRED C_v VALUES FOR
BOLTING MATERIAL TESTED IN ACCORDANCE
WITH NE-2332.3(a)**

Nominal Diameter, in.	Lateral Expansion, mils	Absorbed Energy, ft-lb
1 or less	No test required	No test required
Over 1 through 4	25	No requirements
Over 4	25	45

TABLE NE-2332.3(a)-1 REQUIRED C_v VALUES FOR BOLTING MATERIAL TESTED IN ACCORDANCE WITH NE-2332.2(a)

(b) When tested at 30°F (17°C) or more below the Lowest Service Metal Temperature, lateral expansion and absorbed energy values shall be determined, and all three specimens shall meet the requirements of Table NE-2332.3(b)-1.

NE-2333 Specific Test Methods and Acceptance Standards for Pressure Retaining Material for Tests Based on Lowest Overpressure Test Metal Temperature

NE-2333.1 Pressure Retaining Material Other Than Bolting.

Apply the method of NE-2331(a)(1) to test: the base material; the base material, the heat affected zone, and the weld metal for the weld procedure

**TABLE NE-2332.3(b)-1
REQUIRED C_v VALUES FOR BOLTING MATERIAL
TESTED IN ACCORDANCE WITH

Nominal Wall Thickness, in.	60 ksi or Below		Over 60 ksi	
	Average of 3	Lowest 1 of 3	Average of 3	Lowest 1 of 3
$\frac{5}{8}$ in. or less [Note (3)]	...	...	...	...
Over $\frac{5}{8}$ in.	15	10	20	15

NOTES:

- (1) Where weld metal tests of NE-2400 are made to these requirements, the impact energy shall conform to the requirements of either of the base materials being joined.
- (2) Where two base materials having different required energy values are joined, the weld metal impact energy requirements of the procedure qualification tests of NE-4330 shall conform to the requirements of either of the base materials.
- (3) No test required.

TABLE NE-2333.1-1 REQUIRED C_v ENERGY VALUES FOR PRESSURE RETAINING MATERIAL OTHER THAN BOLTING FOR THE OVERPRESSURE TEST

The impact test results of the three specimens, collectively and singly, shall meet the respective requirements of Table NE-2333.1-1.

NE-2333.2 Bolting Material.

For bolting material, including nuts, studs, and bolts, a Charpy V-notch test shall be performed. The test shall be

performed at or below the Lowest Service Metal Temperature, and all three specimens shall meet the requirements of Table NE-2332.3(a)-1.

NE-2340 NUMBER OF IMPACT TESTS REQUIRED

NE-2341 Plates

One test shall be made from each plate as heat treated. Where plates are furnished in the nonheat-treated condition and qualified by heat treated test specimens, one test shall be made for each plate as-rolled. The term as-rolled refers to the plate rolled from a slab or directly from an ingot, not to its heat treated condition.

NE-2342 Forgings and Castings

(a) Where the weight of an individual forging or casting is less than 1000 lb (454 kg), one test shall be made to represent each heat in each heat treatment lot.

(b) When heat treatment is performed in a continuous type furnace with suitable temperature controls and equipped with recording pyrometers so that complete heat treatment records are available, a heat treatment charge shall be considered as the lesser of a continuous run not exceeding 8 hr duration or a total weight, so treated, not exceeding 2000 lb (907 kg).

(c) One test shall be made for each forging or casting of 1000 lb to 10,000 lb (454 kg to 4540 kg) in weight.

(d) As an alternative to (c), a separate test forging or casting may be used to represent forgings or castings of different sizes in one heat and heat treat lot, provided the test piece is a representation of the greatest thickness in the heat treat lot. In addition, test forgings shall have been subjected to substantially the same reduction and working as the forgings represented.

(e) Forgings or castings larger than 10,000 lb (4540 kg) shall have two tests per part for Charpy V notch, and one test for drop weights. The location of drop weight or C_v impact test specimens shall be selected so that an equal number of specimens is obtained from positions in the forging or casting 180 deg apart.

(f) As an alternative to (e) for static castings, a separately cast test coupon [NE-2226(b)(2)] may be used; one test shall be made for Charpy V-notch and one test for drop weight.

NE-2343 Bars

One test shall be made for each lot of bars with a cross-sectional area greater than 1 sq in. (645 mm²) in each lot, where a lot is defined as one heat of material heat treated in one charge or as one continuous operation, not to exceed 6000 lb (2720 kg).

Page 29

NE-2344 Tubular Products and Fittings

On products which are seamless or welded without filler metal, one test shall be made from each lot. On products which are welded with filler metal, one additional test with the specimens taken from the weld area shall also be made on each lot. A lot shall be defined as stated in the applicable material specification, but in no case shall a lot consist of products from more than one heat of material and of more than one diameter, with the nominal thickness of any product included not exceeding that to be impact tested by more than $\frac{1}{4}$ in. (6 mm); such a lot shall be in a single heat treatment load or in the same continuous run in a continuous furnace controlled within a 50°F (28°C) range and equipped with recording pyrometers.

NE-2345 Bolting Material

One test shall be made for each lot of material where a lot is defined as one heat of material heat treated in one charge or as one continuous operation, not to exceed in weight the following:

$1\frac{3}{4}$ in. diameter and less	1,500 lb
Over $1\frac{3}{4}$ in. to $2\frac{1}{2}$ in. diameter	3,000 lb

Over 5 in. diameter

6,000 lb

10,000 lb

NE-2350 RETESTS

NE-2351 Retests for Material Other Than Bolting

(a) For Charpy V-notch tests required by NE-2330, one retest at the same temperature may be conducted, provided:

(1) the average value of the test results meets the average of three requirements specified in Table NE-2332.1-1, Table NE-2332.1-2, or Table NE-2333.1-1, as applicable;

(2) not more than one specimen per test is below the lowest one of three requirements specified in Table NE-2332.1-1, Table NE-2332.1-2, or Table NE-2333.1-1, as applicable;

(3) the specimen not meeting the requirements is not lower than 5 ft-lb (6.8 J) or 5 mils (0.13 mm) below the lowest one of three requirements specified in Table NE-2332.1-1, Table NE-2332.1-2, or Table NE-2333.1-1, as applicable.

(b) A retest consists of two additional specimens taken as near as practicable to the failed specimens. For acceptance of the retests, both specimens shall be equal to or greater than the average of three requirements specified in Table NE-2332.1-1, Table NE-2332.1-2, or Table NE-2333.1-1, as applicable.

NE-2352 Retests for Bolting Material

(a) For Charpy V-notch tests required by NE-2330, one retest at the same temperature may be conducted, provided:

(1) not more than one specimen per test is below the acceptance requirements;

(2) the specimen not meeting the acceptance requirements is not lower than 5 ft-lb (6.8 J) or 5 mils (0.13 mm) below the acceptance requirements.

(b) A retest consists of two additional specimens taken as near as practicable to the failed specimens. For acceptance of the retests, both specimens shall meet the specified acceptance requirements.

NE-2360 CALIBRATION OF INSTRUMENTS AND EQUIPMENT

Calibration of temperature instruments and C_v impact test machines used in impact testing shall be performed at the frequency specified in (a) and (b) below.

(a) Temperature instruments used to control test temperature of specimens shall be calibrated and the results recorded to meet the requirements of NCA-3868 at least once in each 3 month interval.

(b) C_v impact test machines shall be calibrated and the results recorded to meet the requirements of NCA-3868. The calibrations shall be performed at least once per year using methods outlined in ASTM E 23-72 and employing standard specimens obtained from the National Institute of Standards and Technology.

NE-2400 WELDING MATERIAL

NE-2410 GENERAL REQUIREMENTS

(a) All welding material used in the construction and repair of components or material, except welding material used for hard surfacing, shall conform to the requirements of the welding material specification or to the requirements for other welding material as permitted in Section IX. In addition, welding material shall conform to the requirements stated in this Subarticle and to the rules covering identification in NE-2150.

(b) The Certificate Holder shall provide the organization performing the testing with the information listed below, as applicable:

(1) welding process;

- (3) other identification if no SFA Specification applies;
- (4) minimum tensile strength [NE-2431.1(e)] in the as-welded or heat treated condition, or both [NE-2431.1(c)];
- (5) drop weight test for material as-welded or heat treated, or both (NE-2332);
- (6) Charpy V-notch test for material as-welded, or heat treated, or both (NE-2331); the test temperature and the lateral expansion or the absorbed energy shall be provided;
- (7) the preheat and interpass temperature to be used during welding of the test coupon [NE-2431.1(c)];
- (8) postweld heat treatment time, temperature range, and maximum cooling rate, if the production weld will be heat treated [NE-2431.1(c)];
- (9) elements for which chemical analysis is required per the SFA Specification or WPS, and NE-2432;
- (10) minimum delta ferrite (NE-2433).

NE-2420 REQUIRED TESTS

The required tests shall be conducted for each lot of covered, flux-cored, or fabricated electrodes; for each heat of bare electrodes, rod, or wire for use with the OFW, GMAW, GTAW, PAW, and EGW (electro-gas welding) processes (Section IX, QW-492); for each heat of consumable inserts; for each combination of heat of bare electrodes and lot of submerged arc flux; for each combination of lot of fabricated electrodes and lot of submerged arc flux; for each combination of heat of bare electrodes or lot of fabricated electrodes and dry blend of supplementary powdered filler metal and lot of submerged arc flux; or for each combination of heat of bare electrodes and lot of electroslog flux. Tests performed on welding material in the qualification of weld procedures will satisfy the testing requirements for the lot, heat, or combination of heat and batch of welding material used, provided the tests required by NE-4000 and this Subarticle are made and the results conform to the requirements of this Article. The definitions in (a) through (h) below apply.

(a) A *dry batch of covering mixture* is defined as the quantity of dry covering ingredients mixed at one time in one mixing vessel; a dry batch may be used singly or may be subsequently subdivided into quantities to which the liquid binders may be added to produce a number of wet mixes [(c) below].

(b) A *dry blend* is defined as one or more dry batches mixed in a mixing vessel and combined proportionately to produce a uniformity of mixed ingredients equal to that obtained by mixing the same total amount of dry ingredients at one time in one mixing vessel.

(c) A *wet mix* is defined as the combination of a dry batch or dry blend [(a) and (b) above, respectively] and liquid binder ingredients at one time in one mixing vessel.

(d) A *lot of covered, flux-cored, or fabricated electrodes* is defined as the quantity of electrodes produced from the same combination of heat of metal and dry batch, dry blend, or chemically controlled mixes of flux or core materials. Alternatively, a lot of covered, flux-cored, or fabricated electrodes may be considered one type and size of electrode, produced in a continuous period, not to exceed 24 hr and not to exceed 100,000 lb (45,360 kg), from chemically controlled tube, wire, or strip, and a dry batch, a dry blend, or chemically controlled mixes of flux, provided each container of welding materials is coded for identification and trace able to the production period, the shift, line, and the analysis range of both the mix and the rod, tube, or strip used to make the electrode.

(1) *Chemically controlled tube, wire, or strip* is defined as consumable tube, wire, or strip material supplied on coils with a maximum of one splice per coil that has been chemically analyzed to assure that the material conforms to the electrode manufacturer's chemical control limits for the specific type of electrode. Both ends of each coil shall be chemically analyzed, except that those coils which are splice-free need only be analyzed on one end of the coil.

(2) *Chemically controlled mixes of flux* are defined as flux material that has been chemically analyzed to assure that it conforms to the percent allowable variation from the electrode manufacturer's standard for each chemical element for that type of electrode. A chemical analysis shall be made on each mix made in an individual mixing vessel after blending.

(e) A *heat of bare electrode, rod, wire, or consumable insert* is defined as the material produced from the same melt of metal.

(f) Alternatively, for carbon and low alloy steel bare electrode, rod, wire, or consumable inserts for use with SAW, OFW, GMAW, GTAW, PAW, and EGW processes, a heat may be defined as either the material produced from the same melt of metal or the material produced from one type and size of wire when produced in a continuous period, not to exceed 24 hr and not to exceed 100,000 lb (45,360 kg), from chemically controlled wire, subject to requirements of (1), (2), and (3) below.

(1) For the chemical control of the product of the rod mill, coils shall be limited to a maximum of one splice prior to processing the wire. Chemical analysis

Page 31

shall be made from a sample taken from both ends of each coil of mill coiled rod furnished by mills permitting spliced coil practice of one splice maximum per coil. A chemical analysis need be taken from only one end of rod coils furnished by mills prohibiting spliced coil practice.

(2) Carbon, manganese, silicon, and other intentionally added elements shall be determined to identify the material to ensure that it conforms to the SFA or user's material specification.

(3) Each container of wire shall be coded for identification and traceability to the lot, production period, shift, line, and analysis of rod used to make the wire.

(g) A *lot of submerged arc or electroslag flux* is defined as the quantity of flux produced from the same combination of raw materials under one production schedule.

(h) A *dry blend of supplementary powdered filler metal* is defined as one or more mixes of material produced in a continuous period, not to exceed 24 hr and not to exceed 20,000 lb (9070 kg) from chemically controlled mixes of powdered filler metal, provided each container of powdered metal is coded for identification and traceable to the production period, the shift, and the mixing vessel. A *chemically controlled mix of powdered filler metal* is defined as powdered filler metal material that has been chemically analyzed to assure that it conforms to the percent allowable variation from the powdered filler metal manufacturer's standard, for each chemical element, for that type of powdered filler metal. A chemical analysis shall be made on each mix made in an individual mixing vessel after blending. The chemical analysis range of the supplemental powdered filler shall be the same as that of the welding electrode, and the ratio of powder to electrode used to make the test coupon shall be the maximum permitted for production welding.

NE-2430 WELD METAL TESTS

NE-2431 Mechanical Properties Test

Tensile and impact tests shall be made, in accordance with this paragraph, of welding material which is used to join P-Nos. 1, 3, 4, 5, 6, 7, 9, and 11 base materials in any combination, with the exceptions listed in (a) through (d) below:

(a) austenitic stainless steel and nonferrous welding material used to join the listed P-Numbers;

(b) consumable inserts (backing filler material);

(c) welding material used for GTAW root deposits with a maximum of two layers;

(d) welding material to be used for the welding of base materials exempted from impact testing by NE-2311(a)(1) through (a)(7) and NE-2311(a)(9) shall likewise be exempted from the impact testing required by this paragraph.

NE-2431.1 General Test Requirements.

The welding test coupon shall be made in accordance with (a) through (f) below, using each process with which the weld material will be used in production welding.

(a) Test coupons shall be of sufficient size and thickness such that the test specimens required herein can be removed.

(b) The weld metal to be tested for all processes except electroslag welding shall be deposited in such a manner as to

eliminate substantially the influence of the base material on the results of the tests. Weld metal to be used with the electroslag process shall be deposited in such a manner as to conform to one of the applicable Welding Procedure Specifications (WPS) for production welding, Section IX, QW-201.1. The base material shall conform with the requirements of Section IX, QW-403.1 or Section IX, QW-403.4, as applicable.

7 Any postweld held treatment time which is anticipated to be applied to the material or item after it is completed shall be specified in the Design Specification. The Certificate Holder shall include this time in the total time at a temperature specified to be applied to the test specimens

(c) The welding of the test coupon shall be performed within the range of preheat and interpass temperatures which will be used in production welding. Coupons shall be tested in the as-welded condition, or they shall be tested in the applicable postweld heat treated condition when the production welds are to be postweld heat treated. The postweld heat treatment holding time⁷ shall be at least 80% of the maximum time to be applied to the weld metal in production application. The total time for postweld heat treatment of the test coupon may be applied in one heating cycle. The cooling rate from the postweld heat treatment temperature shall be of the same order as that applicable to the weld metal in the component. In addition, weld coupons for weld metal to be used with the electroslag process that are tested in the as-welded condition, or following a postweld heat treatment within the holding temperature ranges of Table NE-4622.1-1 or Table NE-4622.4(c)-1, shall have a thickness within the range of 0.5 to 1.1 times the thickness of the welds to be made in production. Electroslag weld coupons to be tested following a postweld heat treatment which will include heating the coupon to a temperature above the "Holding Temperature Range" of Table NE-4622.1-1 for the type

Page 32

of material being tested shall have a thickness within the range of 0.9 to 1.1 times the thickness of the welds to be made in production.

(d) Regardless of the welding process or welding material being tested, the tensile specimens, and the C_v impact specimens where required, shall be located and prepared in accordance with the requirements of SFA-5.1, Specification for Mild Steel Covered Electrodes. Drop weight impact test specimens, where required, shall be oriented so that the longitudinal axis is transverse to the weld with the notch in the weld face or in a plane parallel to the weld face. For impact specimen preparation and testing the applicable parts of NE-2321.1 and NE-2321.2 shall apply. The longitudinal axis of the specimen shall be at a minimum depth of $1/4t$ from a surface, where t is the thickness of the test weld.

(e) One all weld metal tensile specimen shall be tested and shall meet the specified minimum tensile strength requirements of the base material specification. Where base materials of different specifications are to be welded, the tensile strength requirements shall conform to the specified minimum tensile strength requirements of either of the base material specifications.

(f) Impact specimens of the weld metal shall be tested where impact tests are required for either of the base materials of the production weld. The weld metal shall conform to the requirements of NE-2332.1, NE-2332.2, or NE-2332.3, as applicable.

NE-2431.2 Standard Test Requirements.

In lieu of the use of the General Test Requirements specified in NE-2431.1, tensile and impact tests may be made in accordance with this subparagraph where they are required for mild and low alloy steel covered electrodes. The material combinations which require weld material testing, as listed in NE-2431, shall apply for this Standard Test Requirements option. The limitations and testing under this Standard Test option shall be in accordance with (a) through (f) below.

(a) Testing to the requirements of this subparagraph shall be limited to electrode classifications included in Specification SFA-5.1 or SFA-5.5.

(b) The test assembly required by SFA-5.1 or SFA-5.5, as applicable, shall be used for test coupon preparation, except that it shall be increased in size to obtain the number of C_v specimens or the drop weight test specimens required by NE-2331, where applicable.

(c) The welding of the test coupon shall conform to the requirements of the SFA Specification for the classification of electrode being tested. Coupons shall be tested in the as-welded condition and also in the postweld heat treated condition. The postweld heat

treatment temperatures shall be in accordance with Table NE-4622.1-1 for the applicable P-Number equivalent. The

time at postweld heat treatment temperature shall be 8 hr (this qualifies postweld heat treatments of 10 hr or less). Where the postweld heat treatment of the production weld exceeds 10 hr, or the PWHT temperature is other than that required above, the general test of NE-2431.1 shall be used.

**TABLE NE-2432.1-1
SAMPLING OF WELDING MATERIALS FOR
CHEMICAL ANALYSIS**

	GTAW/PAW	GMAW	All Other Processes
A-No. 8 filler metal	Filler metal or weld deposit	Weld deposit	Weld deposit
All other filler metal	Filler metal or weld deposit	Filler metal or weld deposit	Weld deposit

TABLE NE-2432.1-1 SAMPLING OF WELDING MATERIALS FOR CHEMICAL ANALYSIS

(d) The tensile and C_v specimens shall be located and prepared in accordance with the requirements of SFA-5.1 or SFA-5.5, as applicable. Drop weight impact test specimens, where required, shall be located and oriented as specified in NE-2431.1(d).

(e) One all weld metal tensile specimen shall be tested and shall meet the specified minimum tensile strength requirement of the SFA Specification for the applicable electrode classification.

(f) The requirements of NE-2431.1(f) shall be applicable to the impact testing of this option.

NE-2432 Chemical Analysis Test

Chemical analysis of filler metal or weld deposits shall be made in accordance with NE-2420 and as required by the following subparagraphs.

NE-2432.1 Test Method.

The chemical analysis test shall be performed in accordance with this subparagraph and Table NE-2432.1-1, and the results shall conform to NE-2432.2.

(a) A-No. 8 welding material to be used with GTAW and PAW processes and any other welding material to be used with any GTAW, PAW, or GMAW process shall have chemical analysis performed either on the filler metal or on a weld deposit made with the filler metal in accordance with (c) or (d) below.

(b) A-No. 8 welding material to be used with other than the GTAW and PAW processes and other welding material to be used with other than the GTAW, PAW, or GMAW process shall have chemical analysis performed

on a weld deposit of the material or combination of materials being certified in accordance with (c) or (d) below. The removal of chemical analysis samples shall be from an undiluted weld deposit made in accordance with (c) below. As an alternative, the deposit shall be made in accordance with (d) below for material that will be used for corrosion resistant overlay cladding. Where the Welding Procedure Specification or the welding material specification specifies percentage composition limits for analysis, it shall state that the specified limits apply for either the filler metal analysis or the undiluted weld deposit analysis or for *in situ* cladding deposit analysis in conformance with the above required certification testing.

(c) The preparation of samples for chemical analysis of undiluted weld deposits shall comply with the method given in the applicable SFA Specification. Where a weld deposit method is not provided by the SFA Specification, the sample shall be removed from a weld pad, groove, or other test weld⁸ made using the welding process that will be followed when the welding material or combination of welding materials being certified is consumed. The weld for A-No. 8 material to be used with the GMAW or EGW process shall be made using the shielding gas composition specified in the Welding Procedure Specification that will be followed when the material is consumed. The test sample for ESW shall be removed from the weld metal of the mechanical properties test coupon. Where a chemical analysis is required for a welding material which does not have a mechanical properties test requirement, a chemical analysis test coupon shall be prepared as required by NE-2431.1(c), except that heat treatment of the coupon is not required and the weld coupon thickness requirements of NE-2431.1(c) do not apply.

(d) The alternate method provided in (b) above for the preparation of samples for chemical analysis of welding material to be used for corrosion resistant overlay cladding shall require a test weld made in accordance with the essential variables of the Welding Procedure Specification that will be followed when the welding material is consumed. The test weld shall be made in conformance with the requirements of Section IX, QW-214.1. The removal of chemical analysis samples shall conform with Section IX, QW-214.3, for the minimum thickness for which the Welding Procedure Specification is qualified.

⁸ The methods given in the appendix of SFA 5.9, specification for Corrosion-Resisting Chromium-Nickel Steel Welding Rods and Bare Electrodes, shall be used to establish a welding and sampling method for the pad, groove, or other test weld to ensure that the weld deposit being sampled will be substantially free of base metal dilution.

TABLE NE-2432.2-1 WELDING MATERIAL CHEMICAL ANALYSIS

Cr-Ni stainless materials	C, Cr, Mo, Ni, Mn, Si, Cb
------------------------------	---------------------------

TABLE NE-2432.2-1 WELDING MATERIAL CHEMICAL ANALYSIS

NE-2432.2 Requirements for Chemical Analysis.

The chemical elements to be determined, the composition requirements of the weld metal, and the recording of results of the chemical analysis shall be in accordance with (a), (b), and (c) below.

(a) Welding material of ferrous alloy A-No. 8 (Section IX, QW-442) shall be analyzed for the elements listed in Table NE-2432.2-1, and for any other elements specified either in the welding material specification referenced by the

Welding Procedure Specification or in the Welding Procedure Specification.

(b) The chemical composition of the weld metal or filler metal shall conform to the welding material specification for elements having specified percentage composition limits. Where the Welding Procedure Specification contains a modification of the composition limits of SFA or other referenced welding material specifications, or provides limits for additional elements, these composition limits of the Welding Procedure Specification shall apply for acceptability.

(c) The results of the chemical analysis shall be reported in accordance with NCA-3867. Elements listed in Table NE-2432.2-1 but not specified in the welding material specification or Welding Procedure Specification shall be reported for information only.

NE-2433 Delta Ferrite Determination

A determination of delta ferrite shall be performed on A-No. 8 weld material (Section IX, QW-442); backing filler metal (consumable inserts); bare electrode, rod, or wire filler metal; or weld metal, except that delta ferrite determinations are not required for SFA-5.4 Type 16-8-2, or A-No. 8 weld filler metal to be used for weld metal cladding.

NE-2433.1 Method.

Delta ferrite determinations of welding material, including consumable insert material, shall be made using a magnetic measuring instrument and weld deposits made in accordance with (b) below. Alternatively, the delta ferrite determinations for welding materials may be performed by the use of chemical analysis of NE-2432 in conjunction with Fig. NE-2433.1-1.

(a) Calibration of magnetic instruments shall conform to AWS-A4.2-91.

GENERAL NOTES:
(a) The actual nitrogen content is preferred. If this is not available, the following applicable nitrogen value shall be used:
(1) GMAW welds: 0.06%, except that when self-shielding flux cored electrodes are used: 0.12%.
(2) Welds made using consumable inserts: 0.06%.
(b) This diagram is derived from the WRC 1982 Diagram, except that the solidification mode lines have been removed for ease of use.

FIG. NE-2433.1-1 WELD METAL DELTA FERRITE CONTENT

FIG. NE-2433.1-1 WELD METAL DELTA FERRITE CONTENT

(b) The weld deposit for magnetic delta ferrite determination shall be made in accordance with NE-2432.1(c).

(c) A minimum of six ferrite readings shall be taken on the surface of the weld deposit. The readings obtained shall be averaged to a single Ferrite Number (FN).

NE-2433.2 Acceptance Standards.

The minimum acceptable delta ferrite shall be 5FN. The results of the delta ferrite determination shall be included in the Certified Material Test Report of NE-2130 or NE-4120.

NE-2440 STORAGE AND HANDLING OF WELDING MATERIAL

Suitable storage and handling of electrodes, flux, and other welding materials shall be maintained. Precautions shall be taken to minimize absorption of moisture by fluxes and cored, fabricated, and coated electrodes.

NE-2500 EXAMINATION AND REPAIR OF PRESSURE RETAINING MATERIAL

NE-2510 PRESSURE RETAINING MATERIAL

Pressure retaining material shall be examined and repaired in accordance with the material specification and as otherwise required by this Subarticle.

NE-2530 EXAMINATION AND REPAIR OF PLATE

NE-2531 Required Examination

Plates shall be examined in accordance with the requirements of the material specification.

NE-2537 Time of Examination

Acceptance examinations shall be performed at the time of manufacture as required in (a), (b), and (c) below.

(a) Examinations required by the material specification shall be performed at the time of manufacture as specified in the material specification.

(b) Radiographic examination of repair welds, when required, may be performed prior to any required postweld heat treatment.

(c) Magnetic particle or liquid penetrant examination of repair welds shall be performed after any required postweld heat treatment, except for P-No. 1 material which may be examined before or after any required postweld heat treatment.

NE-2538 Elimination of Surface Defects

Surface defects shall be removed by grinding or machining provided the requirements of (a) and (b) below are met:

(a) the depression, after defect elimination, is blended uniformly into the surrounding surface;

(b) when the elimination of the defect reduces the thickness of the section below the minimum required by NE-3000, the material shall be repaired in accordance with NE-2539.

NE-2539 Repair by Welding

The Material Organization may repair by welding materials from which defects have been removed, provided the depth of the repair cavity does not exceed one-third of the nominal thickness and the requirements of the following subparagraphs are met. Prior approval of the Certificate Holder shall be obtained.

NE-2539.1 Defect Removal.

The defect shall be removed or reduced to an imperfection of acceptable limit by suitable mechanical or thermal cutting or gouging methods and the cavity prepared for repair (NE-4211.1).

NE-2539.2 Qualification of Welding Procedures and Welders.

The welding procedure and welders or welding operators shall be qualified in accordance with NE-4000 and Section IX.

NE-2539.3 Blending of Repaired Areas.

After repair, the surface shall be blended uniformly into the surrounding surface.

NE-2539.4 Examination of Repair Welds.

Each repair weld shall be examined by the magnetic particle method (NE-2545) or by the liquid penetrant method (NE-2546). In addition, when the depth of the repair cavity exceeds the lesser of $\frac{3}{8}$ in. (10 mm) or 10% of the section thickness, the repair weld shall be radiographed in accordance with and to the applicable acceptance standards of NE-5000. The penetrometer shall be based upon the section thickness of the repaired area.

NE-2539.5 Heat Treatment After Repairs.

The product shall be heat treated after repair in accordance with the requirements of NE-4620.

NE-2539.6 Material Report Describing Defects and Repair.

Each defect repair that is required to be radiographed

Page 36

shall be described in the Certified Material Test Report. The Certified Material Test Report for each piece shall include a chart which shows the location and size of the prepared cavity, the welding material identification, the welding procedure, the heat treatment, and a report of the results of the examinations, including radiographic film.

NE-2540 EXAMINATION AND REPAIR OF FORGINGS AND BARS

NE-2541 Required Examinations

Forgings and bars shall be examined in accordance with the requirements of the material specification, except when magnetic particle or liquid penetrant examination is specifically required by the rules of this Subsection, in which case the examination shall conform to the requirements of NE-2545 or NE-2546 as applicable.

NE-2545 Magnetic Particle Examination

NE-2545.1 Examination Procedure.

The procedure for magnetic particle examination shall be in accordance with the methods of Section V, Article 7.

NE-2545.2 Evaluation of Indications

(a) Mechanical discontinuities at the surface are revealed by the retention of the examination medium. All indications are not necessarily defects, however, since certain metallurgical discontinuities and magnetic permeability variations may produce similar indications which are not relevant.

(b) Any indication in excess of the NE-2545.3 acceptance standards which is believed to be nonrelevant shall be reexamined by the same or other nondestructive examination methods to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. Nonrelevant indications which would mask defects are unacceptable.

(c) Relevant indications are indications which result from imperfections. Linear indications are indications in which the length is more than three times the width. Rounded indications are indications which are circular or elliptical with the

length equal to or less than three times the width. Indications resulting from nonmetallic inclusions are not considered relevant indications.

NE-2545.3 Acceptance Standards

(a) Only imperfections producing indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Imperfections producing the following relevant indications are unacceptable:

(1) any linear indications greater than $\frac{1}{16}$ in. (1.6 mm) long for material less than $\frac{5}{8}$ in. (16 mm) thick, greater than $\frac{1}{8}$ in. (3.2 mm) long for material from $\frac{5}{8}$ in. (16 mm) thick to under 2 in. (51 mm) thick, and $\frac{3}{16}$ in. (4.8 mm) long for material 2 in. (51 mm) thick and greater;

(2) rounded indications with dimensions greater than $\frac{1}{8}$ in. (3.2 mm) for thicknesses less than $\frac{5}{8}$ in. (16 mm) and greater than $\frac{3}{16}$ in. (4.8 mm) for thicknesses $\frac{5}{8}$ in. (16 mm) and greater;

(3) four or more relevant indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more relevant indications in any 6 sq in. (3871 mm²) of area whose major dimension is no more than 6 in. (152 mm) with the dimensions taken in the most unfavorable location relative to the indications being evaluated.

NE-2546 Liquid Penetrant Examinations

NE-2546.1 Examination Procedure.

The procedure for liquid penetrant examination shall be in accordance with the methods of Section V, Article 6.

NE-2546.2 Evaluation of Indications

(a) Mechanical discontinuities at the surface are revealed by bleeding out of the penetrant; however, localized surface discontinuities such as may occur from machining marks or surface conditions may produce similar indications which are not relevant.

(b) Any indication in excess of the NE-2546.3 acceptance standards which is believed to be nonrelevant shall be reexamined to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. Nonrelevant indications and broad areas of pigmentation which would mask defects are unacceptable.

(c) Relevant indications are indications which result from imperfections. Linear indications are indications in which the length is more than three times the width. Rounded indications are indications which are circular or elliptical with the length equal to or less than three times the width.

NE-2546.3 Acceptance Standards

(a) Only imperfections producing indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Imperfections producing the following relevant indications are unacceptable:

(1) any linear indications greater than $\frac{1}{16}$ in. (1.6 mm) long for material less than $\frac{5}{8}$ in. (16 mm)

thick, greater than $\frac{1}{8}$ in. (3.2 mm) long for material from $\frac{5}{8}$ in. (16 mm) thick to under 2 in. (51 mm) thick, and $\frac{3}{16}$ in. (4.8 mm) long for material 2 in. (51 mm) thick and greater;

(2) rounded indications with dimensions greater than $\frac{1}{8}$ in. (3.2 mm) for thicknesses less than $\frac{5}{8}$ in. (16 mm) and greater than $\frac{3}{16}$ in. (4.8 mm) for thicknesses $\frac{5}{8}$ in. (16 mm) and greater;

(3) four or more relevant indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more relevant indications in any 6 sq in. (3871 mm²) of area whose major dimension is no more than 6 in.

(152 mm) with the dimensions taken in the most unfavorable location relative to the indications being evaluated.

NE-2547 Time of Examination

The requirements for time of examination shall be the same as stated in NE-2537.

NE-2548 Elimination of Surface Defects

Elimination of surface defects shall be made in accordance with NE-2538.

NE-2549 Repair by Welding

The requirements for repair by welding shall be the same as stated in NE-2539, except that the depth of repair that is permitted is not limited.

NE-2550 EXAMINATION AND REPAIR OF SEAMLESS AND WELDED (WITHOUT FILLER METAL) TUBULAR PRODUCTS AND FITTINGS

NE-2551 Required Examination

(a) Wrought seamless tubular products and fittings shall comply with the requirements of NE-2557, NE-2558, and NE-2559 in addition to the basic material specification.

(b) Welded (without filler metal) tubular products and fittings shall comply with the requirements of NE-2557, NE-2558, and NE-2559; in addition, the welds shall be examined by one of the following methods:

- (1) ultrasonic examination in accordance with NE-2552;
- (2) eddy current examination in accordance with NE-2554;
- (3) radiographic examination in accordance with NE-2553.

NE-2552 Ultrasonic Examination⁹

NE-2552.1 Examination Procedure for Welds in Pipe and Tubing

(a) *Circumferential Direction 6 frac;34 in. (171 mm) O.D. and Smaller.* The welds in pipe and tubing shall be examined in two circumferential directions. The procedure for ultrasonic examination of pipe and tubing in the circumferential directions shall be in accordance with ASTM E 213-79, Standard Method for Ultrasonic Examination of Pipe and Tubing for Longitudinal Discontinuities, and the requirements of this paragraph. The procedure shall provide a sensitivity which will consistently detect defects that produce indications equal to or greater than the indications produced by standard defects included in the reference specimens specified in NE-2552.3.

(b) *Pipe and Tubing Larger Than 6 frac;34 in. (171 mm) O.D.* The welds in pipe and tubing shall be examined in two circumferential directions. The procedure for ultrasonic examination of pipe and tubing larger than 6³/₄ in. (171 mm) O.D. shall be in accordance with the requirements of SA-388 for angle beam scanning in the circumferential direction or with the requirements of ASTM E 213-79. The reference standard shall be in accordance with NE-2552.3.

(c) *Acceptance Standards.* Products with defects that produce indications in excess of the indications produced by the standard defects in the reference specimen are unacceptable unless the defects are eliminated or repaired in accordance with NE-2558 or NE-2559.

NE-2552.2 Examination Procedure for Welds in Fittings

(a) *Procedure.* The procedure for ultrasonic examination of welds in fittings shall be in accordance with the requirements of recommended practice SA-388 for angle beam examination in two circumferential directions.

(b) *Acceptance Standard.* Fittings shall be unacceptable if angle beam examination results show one or more reflectors which produce indications exceeding in amplitude the indications from the calibrated notch.

NE-2552.3 Reference Specimens

9 The volumetric examination required by this paragraph need only be conducted from one surface.

(a) The reference specimen shall be of the same nominal diameter and thickness and of the same nominal composition and heat treated condition as the product

Page 38

which is being examined. For circumferential scanning, the standard defects shall be axial notches or grooves on the outside and inside surfaces of the reference specimen and shall have a length of approximately 1 in. (25 mm) or less, a width not to exceed $\frac{1}{16}$ in. (1.6 mm) for a square notch or U-notch, a width proportional to the depth for a V-notch, and a depth not greater than the larger of 0.004 in. (0.10 mm) or 5% of the nominal wall thickness.

(b) The reference specimen shall be long enough to simulate the handling of the product being examined through the examination equipment. When more than one standard defect is placed in a reference specimen, the defects shall be located so that indications from each defect are separate and distinct without mutual interference or amplification. All upset metal and burrs adjacent to the reference notches shall be removed.

NE-2552.4 Checking and Calibration of Equipment.

The proper functioning of the examination equipment shall be checked and the equipment shall be calibrated by the use of the reference specimens, as a minimum:

- (a) at the beginning of each production run of a given size and thickness of a given material;
- (b) after each 4 hr or less during the production run;
- (c) at the end of the production run;
- (d) at any time that malfunctioning is suspected.

If, during any check, it is determined that the testing equipment is not functioning properly, all of the product that has been tested since the last valid equipment calibration shall be reexamined.

NE-2553 Radiographic Examination

(a) *General.* When radiographic examination is performed as an alternative for ultrasonic examination of the entire volume of the material, it shall apply to the entire volume of the pipe, tube, or fitting material. Acceptance standards specified for welds shall apply to the entire volume of material examined.

(b) *Examination Procedure.* The radiographic examination shall be performed in accordance with Article 2 of Section V, as modified by NE-5111.

(c) *Acceptance Standard.* Welds that are shown by radiography to have any of the following types of discontinuities are unacceptable:

- (1) any type of crack or zone of incomplete fusion or penetration;
- (2) any other elongated indication which has a length greater than:
 - (a) $\frac{1}{4}$ in. (6 mm) for t up to $\frac{3}{4}$ in. (19 mm), inclusive
 - (b) $\frac{1}{3}t$ for t from $\frac{3}{4}$ in. (19 mm) to $1\frac{1}{4}$ in. (32 mm), inclusive
 - (c) $\frac{3}{4}$ in. (19 mm) for t over $1\frac{1}{4}$ in. (32 mm) where t is the thickness of the thinner portion of the weld;
- (3) any group of aligned indications having an aggregate length greater than t in a length of $12t$, unless the minimum distance between successive indications exceeds $6L$, in which case the aggregate length is unlimited, L being the length of the largest indication;
- (4) rounded indications in excess of that shown as acceptable in Appendix VI.

NE-2554 Eddy Current Examination

This examination method is restricted to materials with uniform magnetic properties and of sizes for which meaningful results can be obtained.

NE-2554.1 Examination Procedure.

The procedure for eddy current examination shall provide a sensitivity that will consistently detect defects by comparison with the standard defects included in the reference specimen specified in NE-2552.3. Products with defects that produce indications in excess of the reference standards are unacceptable unless the defects are eliminated or repaired in accordance with NE-2556 or NE-2557 as applicable.

NE-2554.2 Reference Specimens.

The reference specimen shall be of the same nominal diameter and thickness and of the same nominal composition and heat treated condition as the product that is being examined. The standard shall contain tangential or circumferential notches on the outside surface plus a $\frac{1}{16}$ in. (1.6 mm) diameter hole drilled through the wall. These shall be used to establish the rejection level for the product to be tested. The reference notches shall have a depth not greater than the larger of 0.004 in. (0.10 mm) or 5% of the wall thickness. The width of the notch shall not exceed $\frac{1}{16}$ in. (1.6 mm). The length shall be approximately 1 in. or less. The size of reference specimens shall be as specified in NE-2552.3.

NE-2554.3 Checking and Calibration of Equipment.

The checking and calibration of examination equipment shall be the same as in NE-2552.4.

NE-2557 Time of Examination

(a) Products that are quenched and tempered shall be examined, as required, after the quenching and tempering heat treatment.

(b) Products that are not quenched and tempered shall receive the required examinations as follows.

Page 39

(1) Ultrasonic or eddy current examination, when required, shall be performed after final heat treatment, except postweld heat treatment.

(2) Radiographic examination, when required, may be performed prior to any required postweld heat treatment.

(3) Magnetic particle or liquid penetrant examination of welds, including repair welds, shall be performed after final heat treatment, except that the examination may be performed prior to postweld heat treatment for P-No. 1 (Section IX of the Code) materials of 2 in. (51 mm) and less nominal thickness.

(4) Forgings and rolled bars which are to be bored and/or turned to form tubular parts or fittings shall be examined after boring and/or turning, except for threading. Fittings shall be examined after final forming.

(5) When surface examination is required all external surfaces and all accessible internal surfaces shall be examined, except for bolt holes and threads.

NE-2558 Elimination of Surface Defects

Surface defects shall be removed by grinding or machining, provided the requirements of (a) through (c) below are met:

(a) the depression, after defect elimination, is blended uniformly into the surrounding surface;

(b) after defect elimination, the area is examined by the method which originally disclosed the defect to assure that the defect has been removed or reduced to an imperfection of acceptable size;

(c) if the elimination of the defect reduces the thickness of the section below the minimum required to satisfy the rules of NE-3000, the product shall be repaired in accordance with NE-2559.

NE-2559 Repair by Welding

Repair of defects shall be in accordance with NE-2539.

NE-2560 EXAMINATION AND REPAIR OF TUBULAR PRODUCTS AND FITTINGS WELDED WITH FILLER METAL

NE-2561 Required Examination

(a) Welded (with filler metal) tubular products, such as pipe made in accordance with SA-358, SA-409, SA-671, SA-672, and SA-691 and fittings made in accordance with the WPW grades of SA-234, SA-403, and SA-420 which are made by welding with filler metal, shall be treated as material; however, inspection by an Inspector and stamping with an NPT symbol shall be in accordance with Section III requirements. In addition to the NPT symbol, a numeral 2 shall be stamped below and outside the official Code Symbol.

(b) In addition to the requirements of the material specification and of this Article, all welds shall be examined 100% by radiography in accordance with the basic material specification. When radiographic examination is not specified in the basic material specification, the welds shall be examined in accordance with NE-2563.

(c) Tubular products and fittings which have been radiographed shall be marked to indicate that radiography has been performed. The radiographic film and a radiographic report showing film locations shall be provided with the Certified Material Test Report.

(d) The Authorized Inspector shall certify by signing the Partial Data Report Form NM-1 in accordance with NCA-5290.

NE-2563 Radiographic Examination

The radiographic examination shall be performed in accordance with the requirements of NE-2553.

NE-2567 Time of Examination

The time of examination shall be in accordance with the requirements of NE-2557.

NE-2568 Elimination of Surface Defects

Unacceptable surface defects shall be removed in accordance with the requirements of NE-2558.

NE-2569 Repair by Welding

When permitted by the basic material specification, base material defects shall be repair welded in accordance with the requirements of NE-2559. Repair welding of weld seam defects shall be in accordance with NE-4450.

NE-2570 EXAMINATION AND REPAIR OF STATICALLY AND CENTRIFUGALLY CAST PRODUCTS

In addition to the requirements of the material specifications and of this Article, statically and centrifugally

Page 40

cast products shall comply with the following subparagraphs.

**TABLE NE-2571-1
REQUIRED EXAMINATIONS**

Nominal Pipe Size	Item	Applicable Special Requirements for Class MC Castings
...	...	Cast material shall be examined by either the radiographic or the ultrasonic method, or a combination of the two methods. Castings or sections of castings which have coarse grains or configurations which do not yield meaningful results by ultrasonic examination shall be examined by the radiographic method.

TABLE NE-2571-1 REQUIRED EXAMINATIONS

NE-2571 Required Examination

Cast products shall be examined by the radiographic method, except cast ferritic steels, which shall be examined by either the radiographic or the ultrasonic method, or a combination of both methods as required for the product form by Table NE-2571-1.

NE-2572 Time of Nondestructive Examination

NE-2572.1 Acceptance Examinations.

Acceptance examinations shall be performed at the time of manufacture as stipulated in the following and Table NE-2571-1.

(a) *Ultrasonic Examination.* Ultrasonic examination, if required, shall be performed at the same stage of manufacture as required for radiography.

(b) *Radiographic Examination.* Radiography may be performed prior to heat treatment and may be performed prior to or after finish machining at the following limiting thicknesses.

(1) For finished thicknesses under $2\frac{1}{2}$ in. (64 mm), castings shall be radiographed within 20% of the finished thickness when Type 2 radiographic film is used or within $\frac{1}{2}$ in. (13 mm) of the finished thickness when Type 1 radiographic film is used. The penetrometer and the acceptance reference radiographs shall be based on the finished thickness.

(2) For finished thicknesses from $2\frac{1}{2}$ in. (64 mm) up to 6 in. (152 mm), castings shall be radiographed within 20% of the finished thickness. The penetrometer and the acceptance reference radiographs shall be based on the finished thickness.

(3) For finished thicknesses over 6 in. (152 mm), castings shall be radiographed with $\frac{1}{2}$ in. (13 mm) or 15% of the finished thickness, whichever is greater. The penetrometer and the acceptance reference radiographs shall be based on the finished thickness.

(c) Radiography of castings for pumps and valves may be performed in as-cast or rough machined thickness exceeding the limits of (b)(1), (b)(2), or (b)(3) above, subject to the following conditions.

(1) When the thickness of the as-cast or rough machined section exceeds 2 in. (51 mm), acceptance shall be based on reference radiographs for the next lesser thickness; e.g., if the section being radiographed exceeds $4\frac{1}{2}$ in. (114 mm), use reference radiographs of ASTM E 186-75 (reapproved 1979). The penetrometer shall be based on the thickness of the section being radiographed.

(2) When the thickness of the as-cast or rough machined section is 2 in. (51 mm) or less, the reference radiographs of ASTM E 446-78 shall be used and the penetrometer shall be based on the final section thickness.

(3) Weld ends for a minimum distance of t or $\frac{1}{2}$ in. (13 mm), whichever is less (where t is the design section thickness of the weld), from the final welding end shall be radiographed at a thickness within the limits given in (b)(1), (b)(2), or (b)(3) above as applicable. As an alternative, the weld ends may be radiographed in the as-cast or rough machined thickness in accordance with (a) and (b) above, and the penetrameter shall be based on the final section thickness.

(d) *Magnetic Particle or Liquid Penetrant Examination.* Magnetic particle or liquid penetrant examination shall be performed after the final heat treatment required by the material specification. Repair weld areas shall be examined after postweld heat treatment when a postweld heat treatment is performed, except that repair welds in P-No. 1 (see Section IX of the Code) material 2 in. (51 mm) nominal thickness and less may be examined prior to postweld heat treatment. For cast products with machined surfaces, all finished machine surfaces, except threaded surfaces and small deep holes, shall also be examined by the magnetic particle or the liquid penetrant method.

Page 41

NE-2573 Provisions for Repair of Base Material by Welding

The Material Organization may repair, by welding, products from which defects have been removed, provided the requirements of this Article are met.

NE-2573.1 Defect Removal.

The defects shall be removed or reduced to an imperfection of acceptable size by suitable mechanical or thermal cutting or gouging methods, and the cavity prepared for repair. When thermal cutting is performed, consideration shall be given to preheating the material.

NE-2573.2 Repair by Welding.

The Material Organization may repair castings by welding after removing the material containing unacceptable defects. The depth of the repair is not limited. A cored hole or access hole may be closed by the Material Organization by welding in accordance with the requirements of this paragraph provided the hole is closed by filler metal only. If the hole is closed by welding in a metal insert, the welding shall be performed by a holder of a Certificate of Authorization in accordance with the requirements of the Code.

NE-2573.3 Qualification of Welding Procedures and Welders.

Each manufacturer is responsible for the welding done by his organization and shall establish the procedures and conduct the tests required by NE-4000 and by Section IX of the Code in order to qualify both the welding procedures and the performance of welders and welding operators who apply these procedures. He is also responsible for the welding performed by his subcontractors and shall assure himself that the subcontractors conduct the tests required by NE-4000 and by Section IX of the Code in order to qualify their welding procedures and the performance of their welders and welding operators.

NE-2573.4 Blending of Repaired Areas.

After repair, the surface shall be blended uniformly into the surrounding surface.

NE-2573.5 Examination of Repair Welds

(a) Each repair weld shall be examined by the magnetic particle method in accordance with the requirements of NE-2577 or by the liquid penetrant method in accordance with the requirements of NE-2576. In addition, when radiography is specified in the order for the original casting, repair cavities, the depth of which exceeds the lesser of $\frac{3}{8}$ in. (10 mm) or 10% of the nominal wall thickness, shall be radiographed after repair, except that weld slag, including elongated slag, shall be considered as inclusions under Category B of the applicable reference radiographs. The total area of all inclusions, including slag inclusions, shall not exceed the limits of the applicable severity level of Category B of the reference radiographs. The penetrameter and the acceptance standards for radiographic examination of repair welds shall be based on the actual section thickness at the repair area.

(b) Examination of repair welds in P-No. 1 and P-No. 8 material is not required for pumps and valves with inlet piping

connections NPS 2 (DN 50) and less.

NE-2573.6 Heat Treatment After Repairs.

The material shall be heat treated after repair in accordance with the heat treatment requirements of NE-4620, except that the heating and cooling rate limitations of NE-4623 do not apply.

NE-2573.7 Elimination of Surface Defects.

Surface defects shall be removed by grinding or machining provided the requirements of (a) through (c) below are met:

(a) the depression, after defect elimination, is blended uniformly into the surrounding surface;

(b) after defect elimination, the area is reexamined by the magnetic particle method in accordance with NE-2577 or the liquid penetrant method in accordance with NE-2576 to assure that the defect has been removed or reduced to an imperfection of acceptable size;

(c) if the elimination of the defect reduces the section thickness below the minimum required by the specification or drawing, the casting shall be repaired in accordance with NE-2539.

NE-2573.8 Material Report Describing Defects and Repairs.

Each defect repair exceeding in depth the lesser of $\frac{3}{4}$ in. (19 mm) or 10% of the nominal wall thickness shall be described in the Certified Material Test Report. The Certified Material Test Report for each piece shall include a chart that shows the location and size of the prepared cavity, the welding material identification, the welding procedure, the heat treatment, and the examination results, including radiographic film, when radiography is specified in the order for the original casting.

NE-2574 Ultrasonic Examination of Ferritic Steel Castings

Ultrasonic examination shall be performed in accordance with T-541.4 of Article 5 of Section V. Each manufacturer shall certify that the procedure is in accordance with the requirements of NE-2574 and shall make the procedure available for approval upon request.

Page 42

NE-2574.1 Acceptance Standards

(a) The Quality Levels of SA-609 as shown in Section V shall apply for the casting thicknesses indicated:

(1) Quality Level 1 for thicknesses up to 2 in. (51 mm);

(2) Quality Level 3 for thicknesses 2 in. to 4 in. (51 mm to 102 mm);

(3) Quality Level 4 for thicknesses greater than 4 in. (102 mm).

(b) In addition to the Quality Level requirements stated in (a) above, the requirements in (1) through (5) below shall apply for both straight beam and angle beam examination.

(1) Areas giving indications exceeding the Amplitude Reference Line with any dimension longer than those specified in the following tabulation are unacceptable:

UT Quality Level	Longest Dimension of Area^{10, 11, 12}
1	1.5 in.
2	2.0 in.
3	2.5 in.
4	3.0 in.

(2) Quality Level 1 shall apply for the volume of castings within 1 in. (25 mm) of the surface regardless of the overall thickness.

(3) Discontinuities indicated to have a change in depth equal to or greater than one-half the wall thickness or 1 in. (25 mm) (whichever is less) are unacceptable.

(4) Two or more imperfections producing indications in the same plane with amplitudes exceeding the Amplitude Reference Line and separated by a distance less than the longest dimension of the larger of the adjacent indications are unacceptable if they cannot be encompassed within an area less than that of the Quality Level specified in (b)(1) above.

(5) Two or more imperfections producing indications greater than permitted for Quality Level 1 for castings less than 2 in. in thickness, greater than permitted for Quality Level 2 for thicknesses 2 in.

10 The areas for the Ultrasonic Quality Levels in SA-609 refer to the surface area on the casting over which a continuous indication exceeding the transfer corrected distance amplitude curve is maintained.

11 Area are to be measured from dimensions of the movement of the search unit, using the center of the search unit as the reference point.

12 In certain castings, because of very long metal path distances or curvature of the examination surfaces, the surface area over which a given discontinuity is detected may be considerably larger or smaller than the actual area of the discontinuity in the casting; in such cases, other criteria which incorporate a consideration of beam angles or beam spread must be used for realistic evaluation of the discontinuity.

(51 mm) through 4 in. (102 mm), and greater than permitted for Quality Level 3 for thicknesses greater than 4 in. (102 mm), separated by a distance less than the longest dimension of the larger of the adjacent indications, are unacceptable if they cannot be encompassed in an area less than that of the Quality Level requirements stated in (a) above.

NE-2575 Radiographic Examination

NE-2575.1 Examination.

Cast pressure retaining materials shall be examined by the radiographic method when specified in the order for the original castings, except that cast ferritic steels may be examined by either the radiographic or the ultrasonic method, or a combination of both methods. Castings or sections of castings that have coarse grains or configurations that do not yield meaningful examination results by the ultrasonic method shall be examined by the radiographic method.

NE-2575.2 Extent.

Radiographic examination shall be performed on pressure retaining castings such as vessel heads and flanges, valve bodies, bonnets and disks, pump casings and covers, and piping and fittings. The extent of radiographic coverage shall be of the maximum feasible volume and, when the shape of the casting precludes complete coverage, the coverage shall be at least as exemplified in the typical sketches as shown in Fig. NE-2575.2-1.

NE-2575.3 Examination Procedure.

The radio graphic examination shall be performed in accordance with Article 2 of Section V, with the following modifications.

(a) *Film Selection.* Only Types 1, 2, and 3 are permitted.

(b) *Radiographic Density.* The transmitted film density through the radiographic image of the body of the appropriate penetrometer and the area of interest shall be 1.3 minimum for single film viewing. For composite viewing of multiple film exposures, each film of the composite set shall have a minimum density of 1.0. The maximum density shall be 4.0 for either single or composite viewing. A tolerance of 0.05 in density is allowed for variations between densitometer readings.

(c) The requirements of T-274 and T-285 of Article 2 of Section V need not be met.

(d) *Image Quality Indicator (IQI) Design.* Penetrators shall be manufactured and identified in accordance with the requirements or alternates allowed in SE-142 and Appendices.

(e) *Image Quality Indicator (IQI) Selection.* The radiographic quality level shall be 2-4T for section

thicknesses up to and including $\frac{3}{4}$ in. (19 mm) and 2-2T for section thicknesses greater than $\frac{3}{4}$ in. (19 mm). Radiographic quality is defined in Note 2 of SE-94, Pages 44-44

(a) Typical Volute-Type Pump Case

GENERAL NOTES:

- Radiographic examination areas shall be indicated by a circle at each change of direction. The examination symbol for radiography shall be indicated as RT.
- For nondestructive examination areas of revolution, the area shall be indicated by the examine-all-around symbol: - RT - ⌀
- The sketches are typical and are to be used as a guide for minimum required coverage. Even though a sketch may be titled, "pump" or "valve," the coverage shown by the configurations may be applied interchangeably.

(b) Typical Diffuser-Type Pump Case

(c) Typical Diffuser-Type Pump Case Detail

FIG. NE-2575.2-1 TYPICAL PRESSURE RETAINING PARTS OF PUMPS AND VALVES

FIG. NE-2575.2-1 TYPICAL PRESSURE RETAINING PARTS OF PUMPS AND VALVES (CONT'D)

FIG. NE-2575.2-1 TYPICAL PRESSURE RETAINING PARTS OF PUMPS AND VALVES (CON'T)

(f) When radiographing weld ends of cast valves NPS 4 and less, double-wall radiography may be used subject to the conditions of (a) and (b) below.

(1) The penetrameter thickness shall be based on the design section thickness of the double-wall, excluding the weld preparation lip.

(2) Acceptance standards shall be based on nominal single-wall thickness.

NE-2575.4 Procedure Requirements.

Radiographic examination shall be performed in accordance with a written procedure. Each manufacturer shall certify that the procedure is in accordance with the requirements of NB-2575. The procedure shall be available for the interpretation of the films and shall be submitted together with the radiographs. Each procedure shall include at least the following information:

(a) the type of material to be radiographed;

(b) the material thickness ranges to be radiographed;

(c) the type of radiation source, actual or maximum source size or focal spot, X-ray equipment voltage rating and manufacturer. The equipment manufacturer's or supplier's publications, such as technical manuals, decay curves, or written statements documenting the actual or maximum source size or focal spot, shall be acceptable as source size verification. For X-ray machines 320 kV and less, the focal spot size may be determined by the pinhole method.¹³

(d) type and thickness of intensifying screens and filters;

(e) minimum source-to-film distance.

NE-2575.5 Radiographic Setup Information.

To aid in proper interpretation of radiographs, details of the radiographic examination setup used shall accompany each group of radiographs. As a minimum, the information shall include:

(a) film brand and the type and number of films in the cassette;

(b) for multiple film technique, state whether viewing is to be single or superimposed;

(c) blocking or masking technique, if used;

(d) isotope or X-ray voltage used;

(e) source-to-film distance used;

(f) distance between film and object when film/cassette is not in contact with object;

13 Nondestructive Testing Handbook, Volume 1, First Edition, pp. 14.32, 14.33, "Measuring Focal-spot Size." Also, pp. 20, 21 of Radiography in Modern Industry, Fourth Edition.

(g) geometric arrangement for the radiograph(s) (sketch);

(h) orientation of location markers;

(i) description of how internal markers, when used, locate area of interest;

(j) location markers, such as lead numbers or letters, which shall appear as radiographic images on the film, shall be permanently stamped on the surface of the casting being radiographed in a manner permitting the area of interest on a radiograph to be accurately located on the casting and providing evidence on the radiograph that the extent of coverage required by NE-2575.2 has been obtained. On castings or sections of castings where stamping is not feasible, the radiographic procedure shall so state in which case a radiographic film location map shall be provided.

NE-2575.6 Acceptance Criteria.

Castings shall meet the acceptance requirements of Severity Level 2 of ASTM E 446-72, E 446-75, or E 446-78, Reference Radiographs for Steel Castings up to 2 in. (51 mm) in Thickness; ASTM E 186-67, E 186-73, or E 186-75, Reference Radiographs for Heavy-Walled [2 in. to 4 $\frac{1}{2}$ in. (51 mm to 114 mm)] Steel Castings; or ASTM E 280-68, E 280-72, or E 280-75, Reference Radiographs for Heavy-Walled [4 $\frac{1}{2}$ in. to 12 in. (114 mm to 305 mm)] Steel Castings; as applicable for the thickness being radiographed, except that Category D, E, F, or G defects are not acceptable. The requirements of ASTM E 280-68, E 280-72, or E 280-75 shall apply for castings over 12 in. (305 mm) in thickness.

NE-2576 Liquid Penetrant Examination

(a) Castings shall be examined, if required, on all accessible surfaces by the liquid penetrant method in accordance with Section V of the Code.

(b) *Evaluation of Indications.* All indications shall be evaluated in terms of the acceptance standards. Mechanical discontinuities intersecting the surface are indicated by bleeding out of the penetrant; however, localized surface discontinuities as may occur from machining marks, scale, or dents may produce indications which are not relevant. Any indication in excess of the acceptance standards believed to be nonrelevant shall be reexamined to verify whether actual defects are present. Surface conditioning may precede the reexamination. Nonrelevant indications and broad areas of pigmentation that would mask indications of defects are unacceptable. Relevant indications are those which result from imperfections and have a major dimension greater than $\frac{1}{16}$ in. Linear indications are those whose length is more than three times the width. Rounded

Page 46

indications are those which are circular or elliptical with the length less than three times the width.

(c) *Acceptance Standards.* The following relevant indications are unacceptable:

(1) linear indications greater than $\frac{1}{16}$ in. (1.6 mm) long for materials less than $\frac{5}{8}$ in. (16 mm) thick, greater than $\frac{1}{8}$ in. (3.2 mm) long for materials from $\frac{5}{8}$ in. (16 mm) thick to under 2 in. (51 mm) thick, and $\frac{3}{16}$ in. (4.8 mm) long for materials 2 in. (51 mm) thick and greater;

(2) rounded indications with dimensions greater than $\frac{1}{8}$ in. (3.2 mm) for thicknesses less than $\frac{5}{8}$ in. (16 mm) and greater than $\frac{3}{16}$ in. (3.2 mm) for thicknesses $\frac{5}{8}$ in. (16 mm) and greater;

(3) four or more indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more indications in any 6 sq in. (3871 mm²) of surface with the major dimension of this area not to exceed 6 in. (152 mm) taken in the most unfavorable orientation relative to the indications being evaluated.

NE-2577 Magnetic Particle Examination (for Fretted Steel Products Only)

(a) Castings of magnetic material shall be examined, if required, on all accessible surfaces by a magnetic particle method in accordance with Section V of the Code.

(b) *Evaluation of Indications.* All indications shall be evaluated in terms of the acceptance standards. Mechanical discontinuities intersecting the surface are indicated by retention of the examination medium. All indications are not necessarily defects since certain metallurgical discontinuities and magnetic permeability variations may produce indications that are not relevant. Any indication in excess of the acceptance standard believed to be nonrelevant shall be reexamined to verify whether actual defects are present. Nonrelevant indications which would mask indications of defects are unacceptable. Surface conditioning may precede the reexamination. Relevant indications are those which result from imperfections and have a major dimension greater than $\frac{1}{16}$ in. Linear indications are those whose length is more than three times there with. Rounded indications are those which are circular or elliptical with the length less than three times the width.

(c) *Acceptance Standards.* The following relevant indications are unacceptable:

(1) linear indications greater than $\frac{1}{16}$ in. (1.6 mm) long for materials less than $\frac{5}{8}$ in. (16 mm) thick, greater than $\frac{1}{8}$ in. (3.2 mm) long for materials from $\frac{5}{8}$ in. (16 mm) thick to under 2 in. (51 mm) thick, and $\frac{3}{16}$ in. (4.8 mm) long for materials 2 in. (51 mm) thick and greater;

(2)

(2) rounded indications with dimensions greater than $\frac{1}{8}$ in. (3.2 mm) for thicknesses less than $\frac{1}{8}$ in. (16 mm) and greater than $\frac{3}{16}$ in. (4.8 mm) for thicknesses $\frac{5}{8}$ in. (16 mm) and greater;

(3) four or more relevant indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more relevant indications in any 6 sq in. (3871 mm²) of surface with the major dimension of this area not to exceed 6 in. (152 mm) taken in the most unfavorable orientation relative to the indications being evaluated.

NE-2580 EXAMINATION OF BOLTS, STUDS, AND NUTS

NE-2581 Requirements

All bolting material shall be visually examined in accordance with NE-2582.

NE-2582 Visual Examination

Visual examination shall be applied to the areas of threads, shanks, and heads of final machined parts. Harmful discontinuities such as laps, seams, or cracks that would be detrimental to the intended service are unacceptable.

NE-2600 MATERIAL ORGANIZATIONS' QUALITY SYSTEM PROGRAMS

NE-2610 DOCUMENTATION AND MAINTENANCE OF QUALITY SYSTEM PROGRAMS

(a) Except as provided in (b) below, Material Organizations shall have a Quality System Program or an Identification and Verification Program, as applicable, which meets the requirements of NCA-3800.

(b) The requirements of NCA-3862 shall be met as required by NE-2130. The other requirements of NCA-3800 need not be used by Material Organizations for small products, as defined in (c) below, and for material which is allowed by this Subsection to be furnished with a Certificate of Compliance. For these products, the Certificate Holder's Quality Assurance Program (NCA-4000) shall include measures to provide assurance that the material is furnished in accordance with the material specification and with the applicable special requirements of this Subsection.

Page 47

(c) For the purpose of this paragraph, small products are defined as given in (1) through (3) below:

(1) pipe, tube, pipe fittings, and flanges NPS 2 (DN 50) and less;

(2) bolting materials, including studs, nuts, and bolts of 1 in. (25 mm) nominal diameter and less;

(3) bars with a nominal cross-sectional area of 1 sq in. (645 mm²) and less.

NE-2700 DIMENSIONAL STANDARDS

NE-2710 STANDARDS AND SPECIFICATIONS

Dimensions of standard items shall comply with the standards and specifications listed in Table NE-3132-1.

American Society Of Mechanical Engineers

SEC III D1 NE-3000

ARTICLE NE-3000 DESIGN

Page 49

NE-3100 GENERAL DESIGN

NE-3110 LOADING CRITERIA

NE-3111 Loading Conditions

The loadings that shall be taken into account in designing a vessel shall include, but are not limited to, those in (a) through (i) below:

- (a) internal and external pressure;
- (b) impact loads, including rapidly fluctuating pressure;
- (c) weight of the vessel and normal contents under all conditions, including additional pressure due to static and dynamic head of liquids;
- (d) superimposed loads such as other components, operating equipment, insulation, corrosion resistant or erosion resistant linings, and piping;
- (e) wind loads, snow loads, and vibration loads where specified;
- (f) reactions of supporting lugs, rings, saddles, or other types of supports;
- (g) temperature effects;
- (h) reactions to steam and water jet impingement;
- (i) earthquake loads.

NE-3112 Design Loadings

The containment vessel or portions thereof may be exposed to more than one pressure, temperature, and mechanical load condition as provided in the Design Specifications. The specified design parameters for Design Loadings shall be called Design Pressure, Design Temperature, and Design Mechanical Loads. These specified design parameters shall be used in computations to show compliance with the requirements on Design Loadings in NE-3220.

NE-3112.1 Design Pressure.

The design internal pressure shall not be less than 100% of the maximum containment internal pressure under conditions for which the containment function is required. The design external pressure shall not be less than 100% of the maximum containment external pressure. Stability of the vessel shell may be provided by structures bearing directly against the shell or by structural attachments.

NE-3112.2 Design Temperature

(a) The Design Temperature shall not be less than the maximum containment temperature at the coincident maximum containment pressure. The Design Temperature shall be used in all computations involving Design Pressure and coincidental Design Mechanical Loads.

(b) Where a vessel is heated by external or internal heat generation, the effect of such heating shall be incorporated in the establishment of the vessel Design Temperature.

NE-3112.3 Design Mechanical Loads.

The values of dead loads and any hydrostatic loads coincident with Design Pressure shall be designated as Design Mechanical Loads. These mechanical loads shall be used in all computations involving Design Pressure and Design Temperature.

NE-3112.4 Allowable Stress Intensity and Stress Values.

The rules for allowable stress intensities and allowable stresses are given in NE-3200 for vessels designed by analysis where the allowable stress intensity S_{mc} is 1.1 times the S value given in Section II, Part D, Subpart 1, Tables 1A and 1B, except S_{mc} shall not exceed 90% of the material's yield strength at temperature, shown in Section II, Part D, Table Y-1.

The allowable stress S to be used in the equations of NE-3300 shall be 1.1 times those listed in Section II, Part D, Subpart 1, Tables 1A and 1B for the materials permitted in Table NE-2121(a)-1, except S shall not exceed 90% of the material's yield strength at temperature, shown in Section II, Part D, Table Y-1. The material shall not be used at metal and design temperatures above those for which stress intensity values are listed. The values in the Tables may be interpolated for intermediate temperatures.

NE-3113 Service Limits

Each Service Loading to which the component may be subjected shall be categorized in accordance with the following definitions and shall be described in the Design Specifications (NCA-3250) in such detail as will provide a complete basis for construction in accordance with these rules. The Service Limit categories shall be as defined in the next four subparagraphs.

NE-3113.1 Level A Service Limits.

Level A Service Limits apply to all sustained loads in combination with the plant or system design basis accident loads for which the containment function is required. Other loads, either separately or in combination with the above loads, may also be considered under this service limit.

NE-3113.2 Level B Service Limits.

This service limit applies to those applicable loads subject to Level A Service Limits in combination with loads due to natural phenomena for which the plant must remain operational. Other loads, either separately or in combination with the above loads, may also be considered under this service limit.

NE-3113.3 Level C Service Limits.

This service limit applies to those applicable loads subject to Level A and B Service Limits in combination with loads due to natural phenomena for which safe shutdown of the plant is required. Other loads, either separately or in combination with the above loads, may also be considered under this service limit.

NE-3113.4 Level D Service Limits.

This service limit applies to those loads subject to other service limits in combination with loadings of a local dynamic nature, such as jet impingement, pipe whip, and pipe reaction loads resulting from a postulated pipe rupture, for which the containment function is required.

NE-3113.5 Service Limits.

The Service Limits for design by analysis are specified in NE-3200. The Service Limits for design by formula are specified in NE-3300.

NE-3114 Testing Conditions

Testing conditions are those tests in addition to the ten hydrostatic or pneumatic tests permitted by NE-6222 and NE-6322, including leak tests or subsequent hydrostatic or pneumatic tests.

NE-3120 SPECIAL CONSIDERATIONS

NE-3121 Corrosion

Material subject to thinning by corrosion, erosion, mechanical abrasion, or other environmental effects shall have provision made in the Design Specifications for these effects by indicating the increase in the thickness of the base metal over that determined by the design formulas (NE-2160). Material added or included for these purposes need not be of the same thickness for all areas of the component if different rates of attack are indicated for the various areas. It should be noted that the tests on which the design fatigue curves (Figs. I-9.0) are based did not include tests in the presence of corrosive environments which might accelerate fatigue failure.

NE-3122 Cladding

The rules of this paragraph apply to the design and analysis of clad components constructed of material permitted under this Subsection. When corrosion or erosion of the cladding material is expected, the cladding thickness shall be increased by an amount that in the judgment of the Owner will provide the desired service life.

NE-3122.1 Primary Stresses.

When stress analysis is required, no structural strength shall be attributed to the cladding in satisfying NE-3221.

NE-3122.2 Design Dimensions.

The dimensions given in (a) and (b) below shall be used in the design of the component.

(a) For components subjected to internal pressure, the inside diameter shall be taken at the nominal inner face of the cladding.

(b) For components subjected to external pressure, the outside diameter shall be taken at the outer face of the base metal.

NE-3122.3 Bearing Stresses.

In satisfying NE-3227.1, the presence of cladding shall be included.

NE-3122.4 Maximum Allowable Stress Values

(a) *Integrally Clad Plate Without Credit for Full Cladding Thickness.* Except as permitted in NE-3122.4(b) below, design calculations shall be based on the total thickness of the clad plates less the specified nominal minimum thickness of cladding. A reasonable excess thickness either of the actual cladding or of the same thickness of corrosion resistant weld metal may be included in the design calculations as an equal thickness of base plate. The maximum allowable stress value shall be 1.1 times that given for the base plate

Page 57

material in Section II, Part D, Subpart 1, Tables 1A and 1B.

(b) *Integrally Clad Plate With Credit for Cladding Thickness.* When clad plate conforms to one of the specifications listed in NE-2127(a) and the joints are completed by depositing corrosion resisting weld metal over the weld in the base plate to restore the cladding, the design calculations may be based on a thickness equal to the nominal thickness of the base plate plus S_c/S_b times the nominal thickness of the cladding after any allowance provided for corrosion has been deducted, where

S_c = maximum allowable stress value for the cladding at the Design Temperature, psi

S_b = maximum allowable stress value for the base plate at the Design Temperature, psi

When S_c is greater than S_b , the multiplier S_c/S_b shall be taken equal to unity. The maximum allowable stress value shall be 1.1 times that given for the base plate material in Section II, Part D, Subpart 1, Tables 1A and 1B.

NE-3122.5 Maximum Allowable Temperature

(a) When the design calculations are based on the thickness of base plate exclusive of cladding thickness, the maximum service metal temperature of the vessel shall be that allowed for the base plate material.

(b) When the design calculations are based on the full thickness of clad plate as permitted in NE-3122.4(b), the maximum service metal temperature shall be the lower of the values allowed for the base plate material and the cladding material.

NE-3123 Welds Between Dissimilar Metals

In satisfying the requirements of this Subarticle, caution should be exercised in design and construction involving dissimilar metals having different coefficients of thermal expansion.

NE-3125 Configuration

Accessibility to permit the examinations required by the Edition and Addenda of Section XI as specified in the Design Specification for the component shall be provided in the design of the component.

NE-3130 GENERAL DESIGN RULES

NE-3131 General Requirements

(a) The containment vessel design shall be such that the rules of NE-3200 are satisfied. However, in the absence of substantial¹ mechanical or thermal loads other than pressure, the rules of NE-3300 may be used in lieu of the rules of NE-3200 for those configurations which are explicitly treated in NE-3300.

(b) For vessels, or portions thereof, designed to the rules of NE-3200, the provisions of NE-3133 may be used, if applicable, in lieu of the rules of NE-3222. For those portions designed to the rules of NE-3300, the requirements of NE-3133 shall be met.

NE-3132 Dimensional Standards for Standard Products

Dimensions of standard products shall comply with the standards and specifications listed in Table NE-3132-1 when the standard or specification is referenced in the specific design Subarticle. However, compliance with these standards does not replace or eliminate the requirements for stress analysis when called for by the design Subarticle for a specific component.

NE-3133 Components Under External Loading

NE-3133.1 General.

Rules are given in this paragraph for determining the thickness under external pressure loading in spherical shells, cylindrical shells with or without stiffening rings, and tubular products consisting of pipes, tubes, and fittings. Charts for determining the stresses in shells, hemispherical heads, and tubular products are given in Section II, Part D, Subpart 3.

1 For the purpose of this provision, substantial loads are defined as those which cumulatively result in stresses which exceed 10% of the primary stresses induced by the Design Pressure, such stresses being defined as maximum principal stresses.

NE-3133.2 Nomenclature.

The symbols used in this paragraph are defined as follows:

A	= factor determined from Fig. VII-1100-1 in Section II, Part D, Subpart 3 and used to enter the applicable material chart in Section II, Part D, Subpart 3. For the case of cylinders having D_o/T values less than 10, see NE-3133.3(b). Also, factor determined from the applicable chart in Section II, Part D, Subpart 3 for the material used in a stiffening ring, corresponding to the factor B and the design metal temperature for the shell under consideration.
A_s	= cross-sectional area of a stiffening ring, sq in.
B	= factor determined from the applicable chart in Section II, Part D, Subpart 3 for the material used in a shell or stiffening ring at the design metal temperature, psi

D_o	= outside diameter of the cylindrical shell course or tube under consideration, in.
E	= modulus of elasticity of material at Design Temperature, psi. For external pressure and axial compression design in accordance with this section, the modulus of elasticity to be used shall be taken from the applicable materials chart in Section II, Part D, Subpart 3. (Interpolation may be made between lines for intermediate temperatures.) The modulus of elasticity values shown in Section II, Part D, Subpart 3 for material groups may differ from those values listed in Section II, Part D, Subpart 2, Table TM for specific materials. Section II, Part D, Subpart 3 values shall be applied only to external pressure and axial compression design.
I	= available moment of inertia of the stiffening ring about its neutral axis, parallel to the axis of the shell, in. ⁴
I'	= available moment of inertia of the combined ring-shell cross section about its neutral axis, parallel to the shell, in. ⁴ The width of the shell which is taken as contributing to the combined moment of inertia shall not be greater than $1.10 \sqrt{D_o} \bar{T}_n$ and shall be taken as lying one-half on each side of the centroid of the ring. Portions of shell plates shall not be considered as contributing area to more than one stiffening ring.
I_s	= required moment of inertia of the stiffening ring about its neutral axis parallel to the axis of the shell, in. ⁴
I'_s	= required moment of inertia of the combined

	ring-shell section about its neutral axis parallel to the axis of the shell, in. ⁴
L	= total length of a tube between tubesheets, or the design length of a vessel section, taken as the largest of the following: (1) the distance between head tangent lines plus one-third of the depth of each head if there are no stiffening rings (2) the greatest center-to-center distance between any two adjacent stiffening rings, or (3) the distance from the center of the first stiffening ring to the head tangent line plus one-third of the depth of the head, all measured parallel to the axis of the vessel, in.
L_s	= one-half of the distance from the center line of the stiffening ring to the next line of support on one side, plus one-half of the center line distance to the next line of support on the other side of the stiffening ring, both measured parallel to the axis of the component, in. A line of support is: (1) a stiffening ring that meets the requirements of this paragraph

(2) a circumferential line on a head at one-third the depth of the head from the head tangent line, or

(3) a circumferential connection to a jacket for a jacketed section of a cylindrical shell

P	= external design pressure, psi (gage or absolute, as required)
P_a	= allowable external pressure, psi (gage or absolute, as required)
R	= inside radius of spherical shell, in.
S	= the lesser of 2 times the allowable stress at design metal temperature from Section II, Part D, Subpart 1, Tables 1A and 1B or 0.9 times the tabulated yield strength at design metal temperature from Section II, Part D, Subpart 2, Table Y-1, psi
T	= minimum required thickness of cylindrical shell or tube, or spherical shell, in.
T_n	= nominal thickness used, less corrosion allowance, of a cylindrical shell or tube, in.

(2) Analysis per ANSI B16.28, para. 2.2, is not acceptable.

TABLE NE-3132-1 DIMENSIONAL STANDARDS

NE-3133.3 Cylindrical Shells.

The thickness of a cylindrical shell under external pressure shall be determined by the procedure given in (a) or (b) below.

(a) Cylinders having D_o/T values ≥ 10 :

Step 1: Assume a value for T and determine the ratios L/D_o and D_o/T .

Step 2: Enter Section II, Part D, Subpart 3, Fig. G at the value of L/D_o determined in Step 1. For values of L/D_o greater than 50, enter the chart at a value of $L/D_o = 50$. For values of L/D_o less than 0.05, enter the chart at a value of L/D_o of 0.05.

Step 3: Move horizontally to the line for the value of D_o/T determined in Step 1. Interpolation may be made for intermediate values of D_o/T . From this point of intersection, move vertically downward to determine the value of factor A .

Step 4: Using the value of A calculated in Step 3, enter the applicable material chart in Section II, Part D, Subpart 3 for the material under consideration. Move vertically to an intersection with the material/temperature line for the Design Temperature. Interpolation may be made between lines for intermediate temperatures. In cases where the value of A falls to the right of the end of the material/temperature line, assume an intersection with the horizontal projection of the upper end of the material/temperature line. For values of A falling to the left of the material/temperature line, see Step 7.

Step 5: From the intersection obtained in Step 4, move horizontally to the right and read the value of B .

Step 6: Using this value of B , calculate the value of the maximum allowable external pressure P_a using the following formula:

$$P_a = \frac{4B}{3(D_o/T)}$$

Step 7: For values of A falling to the left of the applicable material/temperature line, the value of P_a can be calculated by using the following formula:

$$P_a = \frac{2AE}{3(D_o/T)}$$

Step 8: Compare P_a with P . If P_a is smaller than P , select a larger value for T and repeat the design procedure until a value of P_a is obtained that is equal to or greater than P .

(b) Cylinders having D_o/T values <10:

Step 1: Using the same procedure as given in (a) above, obtain the value of B . For values of D_o/T less than 4, the value of A can be calculated using the following formula:

$$A = \frac{1.1}{(D_o/T)^2}$$

For values of A greater than 0.10, use a value of 0.10.

Step 2: Using the value of B obtained in Step 1, calculate a value P_{a1} using the following formula:

$$P_{a1} = \left[\frac{2.167}{(D_o/T)} - 0.0833 \right] B$$

Step 3: Calculate a value P_{a2} using the following formula:

$$P_{a2} = \frac{2S}{D_o/T} \left[1 - \frac{1}{D_o/T} \right]$$

Step 4: The smaller of the values of P_{a1} calculated in Step 2, or P_{a2} calculated in Step 3, shall be used for the maximum allowable external pressure P_a . Compare P_a with P . If P_a is smaller than P , select a larger value for T and repeat the design procedure until a value for P_a is obtained that is equal to or greater than P .

NE-3133.4 Spherical Shells and Formed Heads

(a) *Spherical Shells*. The minimum required thickness of a spherical shell under external pressure, either seamless or of built-up construction with butt joints, shall be determined by the procedure given in Steps 1 through 6.

Step 1: Assume a value for T and calculate the value of factor A using the following formula:

$$A = \frac{0.125}{(R/T)}$$

Step 2: Using the value of A calculated in Step 1, enter the applicable material chart in Section II, Part D, Subpart 3 for the material under consideration. Move vertically to an intersection with the material/temperature line for the Design Temperature. Interpolation may be made between lines for intermediate temperatures. In cases where the value at A falls to the right of the end of the material/temperature line, assume an intersection with the horizontal projection of the upper end of the material/temperature line. For values at A falling to the left of the material/temperature line, see Step 5.

Step 3: From the intersection obtained in Step 2, move horizontally to the right and read the value of factor B .

Step 4: Using the value of B obtained in Step 3, calculate the value of the maximum allowable external pressure P_a using the following formula:

$$P_a = \frac{B}{(R/T)}$$

Step 5: For values of A falling to the left of the applicable material/temperature line for the Design Temperature, the value of P_a can be calculated using the following formula:

$$P_a = \frac{0.0625E}{(R/T)^2}$$

Step 6: Compare P_a obtained in Steps 4 or 5 with P . If P_a is smaller than P , select a larger value for T and repeat the design procedure until a value for P_a is obtained that is equal to or greater than P .

(b) The nomenclature defined below is used in the formulas of (c) through (e) below.

D_o	= outside diameter of the head skirt or the outside diameter of a cone head at the point under consideration, measured perpendicular to the longitudinal axis of the cone, in.
K_1	= a factor depending on the ellipsoidal head proportions, given in Table NE-3332.2-1
R	= for hemispherical heads, the inside radius in the corroded condition, in. = for ellipsoidal heads, the equivalent inside spherical radius taken as $K_1 D_o$ in the corroded condition, in. = for torispherical heads, the inside radius of the crown portion of the head in the corroded condition, in.
T	= minimum required thickness of head after forming, exclusive of corrosion allowance, in.

(c) *Hemispherical Heads.* The required thickness of a hemispherical head having pressure on the convex side shall be determined in the same manner as outlined in (a) above for determining the thickness for a spherical shell.

(d) *Ellipsoidal Heads.* The required thickness of an ellipsoidal head having pressure on the convex side, either seamless or of built-up construction with butt joints, shall not be less than that determined by the following procedure:

Page 61

Step 1: Assume a value for T and calculate the value of factor A using the following formula:

$$A = \frac{0.125}{(R/T)}$$

Step 2: Using the value of A calculated in Step 1, follow the same procedure as that given for spherical shells in (a) above, Steps 2 to 6.

(e) *Torispherical Heads*. The required thickness of a torispherical head having pressure on the convex side, either seamless or of built-up construction with butt joints, shall not be less than that determined by the same design procedure as is used for ellipsoidal heads given in (d) above, using the appropriate value for R .

NE-3133.5 Stiffening Rings for Cylindrical Shells

(a) The required moment of inertia of a circumferential stiffening ring shall not be less than that determined by one of the following two formulas:

$$I_s = \frac{D_o^2 L_s \left(T + \frac{A_s}{L_s} \right) A}{14}$$

$$I'_s = \frac{D_o^2 L_s \left(T + \frac{A_s}{L_s} \right) A}{10.9}$$

If the stiffeners should be so located that the maximum permissible effective shell sections overlap on either or both sides of a stiffener, the effective shell section for the stiffener shall be shortened by one-half of each overlap.

(b) The available moment of inertia I or I' for a stiffening ring shall be determined by the following procedure.

Step 1: Assuming that the shell has been designed and $D_o L_s$ and T_n are known, select a member to be used for the stiffening ring and determine its cross-sectional area A_s . Then calculate factor B using the following formula:

$$B = 3/4 \left(\frac{PD_o}{T_n + A_s/L_s} \right)$$

Step 2: Enter the right side of the applicable material chart in Section II, Part D, Subpart 3 for the material under consideration at the value of B determined by Step 1. If different materials are used for the shell and stiffening ring, use the material chart resulting in the larger value of A in Step 4 or 5 below.

Step 3: Move horizontally to the left to the material/temperature line for the design metal temperature. For values of B falling below the left end of the material/temperature line, see Step 5.

Step 4: Move vertically to the bottom of the chart and read the value of A .

Step 5: For values of B falling below the left end of the material/temperature line for the Design Temperature, the value of A can be calculated using the formula:

$$A = \frac{2B}{E}$$

Step 6: Compute the value of the required moment of inertia from the formulas for I_s or I'_s above.

Step 7: Calculate the available moment of inertia I or I' of the stiffening ring using the section corresponding to that used in Step 6.

Step 8: If the required moment of inertia is greater than the moment of inertia for the section selected in Step 1, a new

section with a larger moment of inertia must be selected and a new moment of inertia determined. If the required moment of inertia is smaller than the moment of inertia for the section selected in Step 1, that section should be satisfactory.

(c) For fabrication and installation requirements for stiffening rings, see NE-4437.

NE-3133.6 Cylinders Under Axial Compression.

The maximum allowable compressive stress to be used in the design of cylindrical shells and tubular products subjected to loadings that produce longitudinal compressive stresses in the shell shall be the smaller of the following values:

(a) 1.1 times the S_m value for the applicable material at Design Temperature given in Section II, Part D, Subpart 1, Tables 1A and 1B.

(b) the value of B determined from the applicable chart in Section II, Part D, Subpart 3, using the following definitions for the symbols on the charts:

T = minimum required thickness of the shell or tubular product, exclusive of the corrosion allowance, in.

R = the inside radius of the cylindrical shell or tubular product, in.

Page 62

The value of B shall be determined from the applicable chart contained in Section II, Part D, Subpart 3 as given in Steps 1 through 5.

Step 1: Using the selected values of T and R , calculate the value of factor A using the following formula:

$$A = \frac{0.125}{(R/T)}$$

Step 2: Using the value of A calculated in Step 1, enter the applicable material chart in Section II, Part D, Subpart 3 for the material under consideration. Move vertically to an intersection with material/temperature line for the Design Temperature. Interpolation may be made between lines for intermediate temperatures. In cases where the value at A falls to the right of the end of the material/temperature line, assume an intersection with the horizontal projection of the

falls to the right of the end of the material/temperature line, assume an intersection with the horizontal projection of the upper end of the material/temperature line. For values of A falling to the left of the material/temperature line, see Step 4.

Step 3: From the intersection obtained in Step 2, move horizontally to the right and read the value of factor B . This is the maximum allowable compressive stress for the values of T and R used in Step 1.

Step 4: For values of A falling to the left of the applicable material/temperature line, the value of B shall be calculated using the following formula:

$$B = \frac{AE}{2}$$

Step 5: Compare the value of B determined in Steps 3 or 4 with the computed longitudinal compressive stress in the cylindrical shell or tube, using the selected values of T and R . If the value of B is smaller than the computed compressive stress, a greater value of T must be selected and the design procedure repeated until a value of B is obtained which is greater than the compressive stress computed for the loading on the cylindrical shell or tube.

NE-3133.7 Conical Heads.

The required thickness of a conical head under pressure on the convex side shall not be less than that determined by (a), (b), and (c) below.

(a) When one-half of the included apex angle of the cone is equal to or less than $22\frac{1}{2}$ deg, the thickness of the cone shall be the same as the required thickness of a cylindrical shell, the length of which equals the axial length of the cone or the axial distance center-to-center of stiffening rings, if used, and the outside diameter of which is equal to the outside diameter at the large end of the cone or section between stiffening rings.

(b) When one-half of the included apex angle of the cone is greater than $22\frac{1}{2}$ deg and not more than 60 deg, the thickness of the cone shall be the same as the required thickness of a cylindrical shell, the outside diameter of which equals the largest inside diameter of the cone measured perpendicular to the cone axis, and the length of which equals an axial length that is the lesser of either the distance center-to-center of stiffening rings, if used, or the largest inside diameter of the section of the cone considered.

(c) When one-half of the included apex angle of the cone is greater than 60 deg, the thickness of the cone shall be the same as the required thickness for a flat head under external pressure, the diameter of which equals the largest inside diameter of the cone (NE-3325).

NE-3134 Material Properties

Values for intermediate temperatures may be found by interpolation.

NE-3134.1 Yield Strength Values.

The values of yield strength S_y shall be those given in Section II, Part D, Subpart 2, Table Y-1.

NE-3134.2 Ultimate Tensile Strength Values.

The values of ultimate tensile strength shall be those given in Section II, Part D, Subpart 2, Table TCD.

NE-3134.3 Coefficients of Thermal Conductivity and Thermal Diffusivity.

The values shall be those given in Section II, Part D, Subpart 2, Table TCD.

NE-3134.4 Coefficients of Thermal Expansion.

The values of thermal expansion coefficients shall be those given in Section II, Part D, Subpart 2, Table TE.

NE-3134.5 Modulus of Elasticity Values.

The values of modulus of elasticity shall be those given in Section II, Part D, Subpart 2, Table TM.

NE-3134.6 Allowable Stress Intensity and Stress Values.

The allowable stress intensity S_{m1} shall be the S_m listed in Section II, Part D, Subpart 1, Tables 2A and 2B, and the allowable stress intensity S_{mc} shall be 1.1 times the S_m listed in Section II, Part D, Subpart 1, Tables 1A and 1B. The basis for establishing allowable

Page 63

stress intensity and stress values is given in Appendix III.

NE-3135 Attachments

(a) Except as in (c) and (d) below, attachments and connecting welds within the jurisdictional boundary of the containment vessel as defined in NE-1130 shall meet the stress limits of NE-3200 or NE-3300.

(b) The design of the containment vessel shall include consideration of the interaction effects and loads transmitted through the attachment to and from the pressure retaining portion of the vessel. Thermal stresses, stress concentrations, and restraint of the pressure retaining portion of the vessel shall be considered.

(c) Beyond $2t$ from the pressure retaining portion of the containment vessel, where t is the nominal thickness of the pressure retaining material, the appropriate design rules of NF-3000 may be used as a substitute for the design rules of NE-3000 for portions of attachments which are in the vessel support load path.

(d) Nonstructural attachments shall meet the requirements of NE-4435.

NE-3200 DESIGN BY ANALYSIS

NE-3210 DESIGN CRITERIA

NE-3211 General Requirements for Acceptability

The requirements for the acceptability of a design by analysis are given in (a) and (b) below.

(a) The design shall be such that stress intensities do not exceed the applicable limits at temperature described in this Subarticle.

(b) In addition to the requirement in (a) above, the buckling stress shall be considered in accordance with NE-3222.

NE-3212 Basis for Determining Stresses

The theory of failure used in the rules of this Subsection for combining stresses is the maximum shear stress theory. The maximum shear stress at a point is equal to one-half the difference between the algebraically largest and the algebraically smallest of the three principal stresses at the point.

NE-3213 Terms Relating to Stress Analysis

Terms used in this Subsection relating to stress analysis are defined in the following subparagraphs.

NE-3213.1 Stress Intensity.²

Stress intensity is the equivalent intensity of combined stress, or, in short, the stress intensity is defined as twice the maximum shear stress. In other words, the stress intensity is the difference between the algebraically largest principal stress and the algebraically smallest principal stress at a given point. Tensile stresses are considered positive and compressive stresses are considered negative.

NE-3213.2 Gross Structural Discontinuity.

Gross structural discontinuity is a geometric or material discontinuity which affects the stress or strain distribution through the entire wall thickness of the pressure retaining member. Gross discontinuity type stresses are those portions of the actual stress distributions that produce net bending and membrane force resultants when integrated through the wall thickness. Examples of gross structural discontinuities are head-to-shell and flange-to-shell junctions, nozzles, and junctions between shells of different diameters or thicknesses.

NE-3213.3 Local Structural Discontinuity.

Local structural discontinuity is a geometric or material discontinuity which affects the stress or strain distribution through a fractional part of the wall thickness. The stress distribution associated with a local discontinuity causes only very localized types of deformation or strain and has no significant effect on the shell-type discontinuity deformations. Examples are small fillet radii, small attachments, and partial penetration welds.

NE-3213.4 Normal Stress.

Normal stress is the component of stress normal to the plane of reference. This is also referred to as direct stress. Usually the distribution of normal stress is not uniform through the thickness of a part, so this stress is considered to be made up in turn of two components, one of which is uniformly distributed and equal to the average value of stress across the thickness under consideration, and the other of which varies from this average value with the location across the thickness.

NE-3213.5 Shear Stress.

Shear stress is the component of stress tangent to the plane of reference.

NE-3213.6 Membrane Stress.

Membrane stress is the component of normal stress which is uniformly distributed and equal to the average of stress across the thickness of the section under consideration.

² This definition of stress intensity is not related to the definition of stress intensity applied in the field of Fracture Mechanics.

NE-3213.7 Bending Stress.

Bending stress is the variable component of normal stress described in NE-3213.4.

The variation may or may not be linear across the thickness.

NE-3213.8 Primary Stress.

Primary stress is any normal stress or a shear stress developed by an imposed loading which is necessary to satisfy the laws of equilibrium of external and internal forces and moments. The basic characteristic of a primary stress is that it is not self-limiting. Primary stresses which considerably exceed the yield strength will result in failure or, at least, in gross distortion. A thermal stress is not classified as a primary stress. Primary membrane stress is divided into general and local categories. A general primary membrane stress is one which is so distributed in the structure that no redistribution of load occurs as a result of yielding. Examples of primary stresses are:

- (a) general membrane stress in a circular, cylindrical, or a spherical shell due to internal pressure or to distributed live loads;
- (b) bending stress in the central portion of a flat head due to pressure.

NE-3213.9 Secondary Stress.

Secondary stress is a normal stress or a shear stress developed by the constraint of adjacent material or by self-constraint of the structure. The basic characteristic of a secondary stress is that it is self-limiting. Local yielding and minor distortions can satisfy the conditions which cause the stress to occur, and failure from one application of the stress is not to be expected. Examples of secondary stresses are:

- (a) general thermal stresses [NE-3213.13(a)];
- (b) bending stress at a gross structural discontinuity.

[98]

NE-3213.10 Local Primary Membrane Stress.

Cases arise in which a membrane stress produced by pressure or other mechanical loading and associated with a discontinuity would, if not limited, produce excessive distortion in the transfer of load to other portions of the structure. Conservatism requires that such a stress be classified as a local primary membrane stress even though it has some characteristics of a secondary stress. A stressed region may be considered local if the distance over which the membrane stress intensity exceeds $1.1S_{mc}$ does not extend in the meridional direction more than $1.0\sqrt{Rt}$, where R is the minimum midsurface radius of curvature and t is the minimum thickness in the region considered. Regions of local primary stress intensity involving axisymmetric membrane stress distributions which exceed $1.1S_{mc}$ shall not be closer in the meridional direction than $2.5\sqrt{Rt}$, where R is defined as $(R_1 + R_2)/2$ and t is defined as $(t_1 + t_2)/2$, where t_1 and t_2 are the minimum thicknesses at each of the regions considered, and R_1 and R_2 are the minimum midsurface radii of curvature at these regions where the membrane stress intensity exceeds $1.1S_{mc}$. Discrete regions of local primary membrane stress intensity, such as those resulting from concentrated loads acting on brackets, where the membrane stress intensity exceeds $1.1S_{mc}$ shall be spaced so that there is no overlapping of the areas in which the membrane stress intensity exceeds $1.1S_{mc}$.

[98]

NE-3213.11 Peak Stress.

Peak stress is that increment of stress which is additive to the primary plus secondary stresses by reason of local discontinuities or local thermal stress [NE-3213.13(b)] including the effects, if any, of stress concentrations. The basic characteristic of a peak stress is that it does not cause any noticeable distortion and is objectionable only as a possible source of a fatigue crack or a brittle fracture. A stress which is not highly localized falls into this category if it is of a type which cannot cause noticeable distortion. Examples of peak stresses are:

- (a) the thermal stress in the austenitic steel cladding of a carbon steel component;
- (b) certain thermal stresses which may cause fatigue, but not distortion;
- (c) the stress at a local structural discontinuity;
- (d) surface stresses produced by thermal shock.

NE-3213.12 Load Stress.

Load stress is the stress resulting from the application of a load, such as internal pressure or the effects of gravity, as distinguished from thermal stress.

NE-3213.13 Thermal Stress.

Thermal stress is a self-balancing stress produced by a nonuniform distribution of temperature or by differing thermal coefficients of expansion. Thermal stress is developed in a solid body whenever a volume of material is prevented from assuming the size and shape that it normally should under a change in temperature. For the purpose of establishing allowable stresses, two types of thermal stress are recognized, depending on the volume or area in which distortion takes place, as described in (a) and (b) below.

(a) General thermal stress is associated with distortion of the structure in which it occurs. If a stress of this type, neglecting stress concentrations, exceeds twice the yield strength of the material, the elastic analysis may be invalid, and successive thermal cycles may produce incremental distortion. Therefore, this type is classified as secondary stress in Table NE-3217-1. Examples of general thermal stresses are:

(1) stress produced by an axial temperature distribution in a cylindrical shell;

Page 65

(2) stress produced by the temperature difference between a nozzle and the shell to which it is attached;

(3) the equivalent linear stress³ produced by the radial temperature distribution in a cylindrical shell.

(b) Local thermal stress is associated with almost complete suppression of the differential expansion and thus produces no significant distortion. Such stresses shall be considered only from the fatigue standpoint and are therefore classified as local stresses in Table NE-3217-1. In evaluating local thermal stresses, the procedures of NE-3228.1(c) shall be used. Examples of local thermal stresses are:

(1) the stress in a small hot spot in a vessel wall;

(2) the difference between the actual stress and the equivalent linear stress resulting from a radial temperature distribution in a cylindrical shell;

(3) the thermal stress in a cladding material which has a coefficient of expansion different from that of the base metal.

NE-3213.14 Total Stress.

Total stress is the sum of the primary, secondary, and peak stress contributions. Recognition of each of the individual contributions is essential to establishment of appropriate stress limitations.

NE-3213.15 Service Cycle.

Service cycle is defined as the initiation and establishment of new conditions followed by a return to the conditions which prevailed at the beginning of the cycle. The types of service conditions which may occur in a containment vessel are further illustrated in NE-3113.

NE-3213.16 Stress Cycle.

Stress cycle is a condition in which the alternating stress difference (NE-3221.5) goes from an initial value through an algebraic maximum value and an algebraic minimum value and then returns to the initial value. A single operational cycle may result in one or more stress cycles. Dynamic effects shall also be considered as stress cycles.

NE-3213.17 Fatigue Strength Reduction Factor.

Fatigue strength reduction factor is a stress intensification factor which accounts for the effect of a local structural discontinuity (stress concentration) on the fatigue strength. Values for some specific cases, based on experiment, are given in NE-3338. In the absence of experimental data, the theoretical stress concentration factor may be used.

³ Equivalent linear stress is defined as the linear stress distribution which has the same net bending moment as the actual stress distribution.

NE-3213.18 Shakedown.

Shakedown is the absence of a continuing cycle of plastic deformation. A structure shakes down if, after a few cycles of load application, the deformation stabilizes and subsequent structural response is elastic, excluding creep effects.

NE-3213.19 Free End Displacement.

Free end displacement consists of the relative motions that would occur between a fixed attachment and connected piping if the two members were separated and permitted to move.

NE-3213.20 Expansion Stresses.

Expansion stresses are those stresses resulting from restraint of free end displacement of the piping system.

NE-3213.21 Limit Analysis - Collapse Load.

The methods of limit analysis are used to compute the maximum load or combination of loads a structure made of ideally plastic (nonstrain-hardening) material can carry. The deformations of an ideally plastic structure increase without bound at this load, which is termed the *collapse load*. Among the methods used in limit analysis is a technique which assumes elastic, perfectly plastic, material behavior and a constant level of moment or force in those redundant structural elements in which membrane yield, plastic hinge, or critical buckling load has been reached. Any increase in load must be accompanied by a stable primary structure until a failure mechanism defined by the lower bound theorem of limit analysis is reached in the primary structure.

NE-3213.22 Collapse Load - Lower Bound.

If, for a given load, any system of stresses can be found which everywhere satisfies equilibrium and nowhere exceeds the material yield strength, the load is at or below the collapse load. This is the lower bound theorem of limit analysis which permits calculations of a lower bound to the collapse load.

NE-3214 Stress Analysis

When required by NE-3130, a detailed stress analysis of all major structural components shall be prepared in sufficient detail to show that each of the stress limitations of NE-3220 and NE-3230 is satisfied when the vessel is subjected to the loadings of NE-3110. As an aid to the evaluation of these stresses, formulas and methods for the solution of certain recurring problems have been placed in Appendix A.

NE-3215 Derivation of Stress Intensities

One requirement for the acceptability of a design (NE-3210) is that the calculated stress intensities shall not exceed specified allowable limits. These limits differ

Page 66

depending on the stress category (primary, secondary, etc.) from which the stress intensity is derived. This paragraph describes the procedure for the calculation of the stress intensities which are subject to the specified limits. The steps in the procedure are stipulated in (a) through (e) below.

(a) At the point on the component which is being investigated, choose an orthogonal set of coordinates such as tangential, longitudinal, and radial, and designate them by the subscripts t , l , and r . The stress components in these directions are then designated σ_t , σ_l , and σ_r for direct stresses and τ_{lr} , $\tau_{lr'}$, and τ_{rt} for shear stresses.

(b) Calculate the stress components for each type of loading to which the part will be subjected and assign each set of stress values to one or a group of the following categories:⁴

- (1) general primary membrane stress P_m (NE-3213.8)
- (2) local primary membrane stress P_L (NE-3213.10)
- (3) primary bending stress P_b (NE-3213.7 and NE-3213.8)

(4) expansion stress P_e (NE-3213.20)

(c) For each category, calculate the algebraic sum of the values of σ_i which result from the different types of loadings and similarly for the other five stress components. Certain combinations of the categories must also be considered.

(d) Translate the stress components for the t , l , and r directions into principal stresses σ_1 , σ_2 , and σ_3 . In many pressure component calculations, the t , l , and r directions may be so chosen that the shear stress components are zero and σ_1 , σ_2 , and σ_3 are identical to σ_p , σ_l , and σ_r .

(e) Calculate the stress differences S_{12} , S_{23} , and S_{31} from the relations:

$$S_{12} = \sigma_1 - \sigma_2$$

$$S_{23} = \sigma_2 - \sigma_3$$

$$S_{31} = \sigma_3 - \sigma_1$$

The stress intensity S_m is the largest absolute value of S_{12} , S_{23} , and S_{31} .

NOTE: Membrane stress intensity is derived from the stress components averaged across the thickness of the section. The averaging shall be performed at the component level, in (b) or (c) above.

⁴ See Table NE-3217-1 and Note (1) of Fig. NE-3221-1.

NE-3216 Derivation of Stress Differences

If the specified operation of the component does not meet the conditions of NE-3221.5(d), the ability of the component to withstand the specified cyclic service without fatigue failure shall be determined as provided in NE-3221.5(e). The determination shall be made on the basis of the stresses at the point of the component, and the allowable stress cycles shall be adequate for the specified service at every point. Only the stress differences due to cyclic Service Loadings as specified in the Design Specifications need be considered.

NE-3216.1 Constant Principal Stress Direction.

For any case in which the directions of the principal stresses at the point being considered do not change during the cycle, the steps stipulated in (a), (b), and (c) below shall be taken to determine the alternating stress intensity.

(a) *Principal Stresses.* Consider the values of the three principal stresses at the point versus time for the complete stress cycle, taking into account both the gross and local structural discontinuities and the thermal effects which vary during the cycle. These are designated as σ_1 , σ_2 , and σ_3 for later identification.

(b) *Stress Differences.* Determine the stress differences $S_{12} = \sigma_1 - \sigma_2$, $S_{23} = \sigma_2 - \sigma_3$, $S_{31} = \sigma_3 - \sigma_1$ versus time for the complete cycle. In what follows, the symbol S_{ij} is used to represent any one of these three stress differences.

(c) *Alternating Stress Intensity.* Determine the extremes of the range through which each stress difference S_{ij} fluctuates and find the absolute magnitude of this range for each S_{ij} . Call this magnitude S_{rij} and let $S_{altij} = 0.5 S_{rij}$. The alternating stress intensity S_{alt} is the largest S_{altij} .

NE-3216.2 Varying Principal Stress Direction.

For any case in which the directions of the principal stresses at the point being considered do change during the stress cycle, it is necessary to use the more general procedure of (a) through (e) below.

(a) Consider the values of the six stress components σ_p , σ_l , σ_r , τ_{lp} , τ_{lr} , τ_{rl} versus time for the complete stress cycle, taking into account both the gross and local structural discontinuities and the thermal effects which vary during the cycle.

(b) Choose a point in time when the conditions are one of the extremes for the cycle (either maximum or minimum, algebraically) and identify the stress components at this time by the subscript i . In most cases it will be possible to choose at least one time during the cycle when the conditions are known to be extreme. In some cases it may be necessary to try different

points in time to find the one which results in the largest value of alternating stress intensity.

(c) Subtract each of the six stress components $\sigma_{1p}, \sigma_{2p}, \sigma_{3p}, \sigma_{4p}, \sigma_{5p}, \sigma_{6p}$ etc., from the corresponding stress components $\sigma_p, \sigma_p, \sigma_p$ etc., at each point in time during the cycle and call the resulting components $\sigma'_p, \sigma'_p, \sigma'_p$ etc.

(d) At each point in time during the cycle, calculate the principal stresses $\sigma'_1, \sigma'_2, \sigma'_3$ derived from the six stress components $\sigma_p, \sigma_p, \sigma_p$ etc. Note that the directions of the principal stresses may change during the cycle but each principal stress retains its identity as it rotates.

(e) Determine the stress differences $S_{12} = \sigma'_1 - \sigma'_2, S_{23} = \sigma'_2 - \sigma'_3, S_{31} = \sigma'_3 - \sigma'_1$ versus time for the complete cycle and find the largest absolute magnitude of any stress difference at any time. The alternating stress intensity S_{alt} is one-half of this magnitude.

NE-3217 Classification of Stresses

Table NE-3217-1 provides assistance in the determination of the category to which a stress should be assigned.

NE-3220 STRESS INTENSITY AND BUCKLING STRESS VALUES FOR OTHER THAN BOLTS

NE-3221 Stress Intensity Values

(a) The stress intensity values for materials of Class MC components are as established in NE-3134. The materials shall not be used at temperatures above those for which stress intensity values are given. The values in the tables may be interpolated for intermediate temperatures.

(b) The stress intensity limits which must be satisfied for the Design and Service Loadings stated in the Design Specifications are the limits of this paragraph and the Special Stress Limits of NE-3227. The provisions of NE-3228 may provide relief from certain of these stress limits if plastic analysis techniques are applied. The stress intensity limits are summarized in Table NE-3221-1 and Fig. NE-3221-1, Fig. NE-3221-2, Fig. NE-3221-3, and Fig. NE-3221-4.

NE-3221.1 General Primary Membrane Stress Intensity.

(Derived from P_m in Fig. NE-3221-1, Fig. NE-3221-2, Fig. NE-3221-3, and Fig. NE-3221-4.) This stress intensity is derived from the average value across the thickness of a section of the general primary stresses (NE-3213.8), produced by pressure and other specified mechanical loads but excluding all secondary and peak stresses. Averaging is to be applied to the stress components prior to determination of the stress intensity values. The allowable Design Limit and the allowable for each of the Service Limits is as given below.

(a) *Design Limit and Level A and B Service Limits.* P_m shall not exceed $1.0S_{mc}$.

(b) *Level C Service Limits*

(1) P_m shall not exceed the greater of $1.2S_{mc}$ or $1.0S_y$ for regions of the vessel which are integral and continuous.

(2) P_m shall not exceed $1.0S_{mc}$ for regions of the vessel which are not integral and continuous, such as bolted flanges and mechanical joints.

(c) *Level D Service Limits*

(1) P_m shall not exceed the greater of the following two values for regions of the containment which are integral and continuous.

(a) 85% of the value permitted in Appendix F. In the application of the rules of Appendix F, S_{m1} , if applicable, shall be as specified in Section II, Part D, Subpart 1, Tables 2A and 2B.

(b) The value established in NE-3221.1(b)(1) for Service Level C limits.

(2) P_m shall not exceed the greater of $1.2S_{mc}$ or $1.0S_y$ for regions of the vessel which are not integral and continuous and at partial penetration welds.

NE-3221.2 Local Membrane Stress Intensity.

(Derived from P_L in Fig. NE-3221-1, Fig. NE-3221-2, Fig. NE-3221-3, and Fig. NE-3221-4.) This stress intensity is derived from the average value across the thickness of a section of the local primary stresses (NE-3213.10) produced by pressure and specified mechanical loads, but excluding all secondary and peak stresses. Averaging is to be applied to the stress components prior to determination of the stress intensity values. The allowable value of this stress intensity is 1.5 times the values given in NE-3221.1, except that the 1.5 factor is not permitted for Level D Service Limits when inelastic component analysis is used as permitted in Appendix F.

NE-3221.3 Primary General or Local Membrane Plus Primary Bending Stress Intensity.

(Derived from $P_L + P_b$ in Fig. NE-3221-1, Fig. NE-3221-2, Fig. NE-3221-3, and Fig. NE-3221-4.) This stress intensity is derived from the highest value, across the thickness of a section, of the general or local primary membrane stress plus primary bending stresses produced by pressure and other loads but excluding all secondary and peak stresses. The allowable Design Limit and the allowable Service Limits are as given in (a) through (d) below.

Page 68

Page 70

Pages 69-69

TABLE NE-3217-1
CLASSIFICATION OF STRESS INTENSITY IN VESSELS FOR SOME TYPICAL CASES¹

Vessel Component	Location	Origin of Stress	Type of Stress	Classification
Cylindrical or spherical shell	Shell plate remote from discontinuities	Internal pressure	General membrane Gradient through plate thickness	P_m Q
		Axial thermal gradient	Membrane Bending	Q Q
	Junction with head or flange	Internal pressure	Membrane Bending	P_L Q [Note (2)]
Any shell or head	Any section across entire vessel	External load or moment, or internal pressure	General membrane averaged across full section	P_m
		External load or moment	Bending across full section	P_m
	Near nozzle or other opening	External load or moment, or internal pressure	Local membrane Bending Peak (fillet or corner)	P_L Q F
	Any location	Temperature difference between shell and head	Membrane Bending	Q Q
Dished head or conical head	Crown	Internal pressure	Membrane Bending	P_m P_b
	Knuckle or junction to shell	Internal pressure	Membrane Bending	P_L [Note (3)] Q
Flat head	Center region	Internal pressure	Membrane Bending	P_m P_b
	Junction to shell	Internal pressure	Membrane Bending	P_L Q [Note (2)]
Perforated head or shell	Typical ligament in a uniform pattern	Pressure	Membrane (through cross section) Bending (through width of ligament, but gradient through plate) Peak	P_m P_b F
	Isolated or atypical ligament	Pressure	Membrane Bending Peak	Q F F

(Table NE-3217-1 continues on next page)

TABLE NE-3217-1 (CONT'D)
CLASSIFICATION OF STRESS INTENSITY IN VESSELS FOR SOME TYPICAL CASES¹

Vessel Component	Location	Origin of Stress	Type of Stress	Classification
Nozzle (NE-3227.5)	Within the limits of reinforcement defined by NB-3334	Pressure and external loads and moments, including those attributable to restrained free end displacements of attached piping	General membrane Bending (other than gross structural discontinuity stresses) averaged through nozzle thickness	P_m P_m
		Pressure and external axial, shear, and torsional loads other than those attributable to restrained free end displacements of the attached piping	General membrane stresses	P_m
	Outside the limits of reinforcement defined by NE-3334	Pressure and external loads and moments other than those attributable to restrained free end displacements of the attached piping	Membrane Bending	P_L P_b
		Pressure, and all external loads and moments	Membrane Bending Peak	P_L Q F
	Nozzle wall	Gross structural discontinuities	Local membrane Bending Peak	P_L Q F
		Differential expansion	Membrane Bending Peak	Q Q F
Cladding	Any	Differential expansion	Membrane Bending	F F
Any	Any	Radial temperature distribution [Note (4)]	Equivalent linear stress [Note (5)]	Q
			Nonlinear portion of stress distribution	F
Any	Any	Any	Stress concentration (notch effect)	F

NOTES:

- (1) Q and F classifications of stresses refer to other than design condition (Fig. NE-3221-2).
- (2) If the bending moment at the edge is required to maintain the bending stress in the middle to within acceptable limits, the edge bending is classified as P_b . Otherwise, it is classified as Q .
- (3) Consideration must also be given to the possibility of wrinkling and excessive deformation in vessels with a large diameter-thickness ratio.
- (4) Consider possibility of thermal stress ratchet.
- (5) Equivalent linear stress is defined as the linear.

TABLE NE-3217-1 (CONT'D) CLASSIFICATION OF STRESS INTENSITY IN VESSELS FOR SOME TYPICAL CASES¹

TABLE NE-3221-1
SUMMARY OF STRESS INTENSITY LIMITS

Symbol	Design Stress Intensity Limit	Loading Condition				
		Level A Service Stress Intensity Limit	Level B Service Stress Intensity Limit and Level C Service Stress Limit Where the Structure Is Not Integral and Continuous	Level C Service Stress Intensity Limit Where the Structure Is Integral and Continuous, and Level D Service Stress Limit Where the Structure Is Not Integral and Continuous, and at Partial Penetration Welds [Note (1)]	Level D Service Stress Intensity Limit Where the Structure Is Integral and Continuous (Elastic Analysis) [Note (2)]	Level D Service Stress Intensity Limit Where the Structure is Integral and Continuous (Inelastic Analysis) [Note (2)]
P_m	$1.0 S_{mc}$	$1.0 S_{mc}$	$1.0 S_{mc}$	$1.2 S_{mc}$ or $* 1.0 S_y$	S_f	S_f
P_L	$1.5 S_{mc}$	$1.5 S_{mc}$	$1.5 S_{mc}$	$1.8 S_{mc}$ or $* 1.5 S_y$	$1.5 S_f$	S_f —
$P_L + P_b$ [Note(3)]	$1.5 S_{mc}$	$1.5 S_{mc}$	$1.5 S_{mc}$	$1.8 S_m$ or $* 1.5 S_y$	$1.5 S_f$	S_f
$P_L + P_b + Q$	N/A [Note(4)]	$3.0 S_{m1}$	$3.0 S_{m1}$ [Note (5)]	N/A [Note (4)]	N/A [Note (4)]	N/A [Note (4)]
$P_L + P_b + Q + F$	N/A [Note(4)]	S_a	S_a [Note (5)]	N/A [Note (4)]	N/A [Note (4)]	N/A [Note (4)]

NOTES:

- (1) Limits identified by (*) indicate a choice of the larger of two limits.
- (2) S_f is 85% of the general primary membrane allowable permitted in Appendix F. In the application of the rules of Appendix F, S_{m1} , if applicable, shall be as specified in Section II, Part D, Subpart 1, Tables 2A and 2B.
- (3) Values shown are for a solid rectangular section. See NE-3221.3(d) for other than a solid rectangular section.
- (4) N/A — No evaluation required.
- (5) Evaluation not required for Level C Service.

TABLE NE-3221-1 SUMMARY OF STRESS INTENSITY LIMITS

(a) *Design Limit and Level A and B Service Limits.* For solid rectangular sections, 1.5 times the value given in NE-3221.1.

(b) *Level C Service Limits*

(1) For solid rectangular sections where the structure is integral and continuous, 1.5 times the value given in NE-3221.1 for P_L less than or equal to $0.67 S_y$, and $(2.5 - 1.5 P_L / S_y)$ times the value given in NE-3221.1 for P_L greater than $0.67 S_y$. S_y is tabulated yield strength at temperature.

(2) For solid rectangular sections when the structure is not integral and continuous, 1.5 times the value given in NE-3221.1

(c) *Level D Service Limits*

(1) When elastic analysis is used for solid rectangular sections where the structure is integral and continuous, 1.5 times the value given in NE-3221.1.

(2) When elastic analysis is used for solid rectangular sections where the structure is not integral and continuous, 1.5 times the value given in NE-3221.1 for P_L less than or equal to $0.67 S_y$ and $(2.5 - 1.5 P_L / S_y)$ times the value given in NE-3221.1 for P_L greater than $0.67 S_y$.

(3) When inelastic component analysis is used, this Service Limit shall be 85% of the value permitted in Appendix F.

(d) For other than solid rectangular sections, a value of α times the limit established in NE-3221.1 may be used, where the factor α is defined as the ratio of the load set producing a fully plastic section divided by the load set producing initial yielding in the extreme fibers of the section. In the evaluation of the initial yield and fully plastic section capacities, the ratios of each individual load in the respective load set to each other load in that load set shall be the same

as the respective ratios of the individual loads in the specified design load set. The value of α shall not exceed the value calculated for bending only ($P_m = 0$). In no case shall the value of α exceed 1.5. The propensity for buckling of the part of the section that is in compression shall be investigated. The α factor is not permitted for Level D Service Limits when inelastic component analysis is used as permitted in Appendix F.

NE-3221.4 Primary Plus Secondary Stress Intensity.

This stress intensity is derived from the highest value, at any point across the thickness of a section, of the general or local primary membrane stresses, plus primary bending stresses plus secondary stresses, produced by the specified conditions. The allowable

value of the maximum range⁵ of this stress intensity is $3.0S_{m1}$ for Level A and B Service Limits. Secondary stresses need not be evaluated for Design Loadings or for Level C and D Service Limits.

- NOTES:
- (1) The symbols P_m , P_L , and P_b do not represent single quantities, but rather sets of six quantities representing the six stress components σ_x , σ_y , σ_z , τ_{xy} , τ_{yz} , and τ_{zx} .
- (2) Value shown is for a solid rectangular section. See NE-3221.3(d) for other than a solid rectangular section.

FIG. NE-3221-1 STRESS CATEGORIES AND LIMITS OF STRESS INTENSITY FOR DESIGN CONDITIONS

FIG. NE-3221-1 STRESS CATEGORIES AND LIMITS OF STRESS INTENSITY FOR DESIGN CONDITIONS

⁵ The concept of stress differences discussed in NE-3216 is essential to determination of the maximum range, since algebraic signs must be retained in the computation. Note that this limitation on range is applicable to the entire history of service conditions, not just to the stresses resulting from each individual service condition.

[98]

NE-3221.5 Analysis for Cyclic Operation

(a) *Suitability for Cyclic Condition.* The suitability of a vessel or part for specified Service Loadings involving cyclic application of loads and thermal conditions shall be determined by the methods described herein, except that the suitability of high strength bolts shall be determined by the methods of NE-3232.3(b) and the possibility of thermal stress ratchet shall be investigated in accordance with NE-3221.6. If the specified Service Loadings for the component meet all of the requirements of NE-3221.5(d), no analysis for cyclic service is required, and it may be assumed that the limits on peak stress intensities as governed by fatigue have been satisfied by compliance with the applicable requirements for materials, design, fabrication, examination, and testing of this Subsection. If the specified Service Loadings do not meet all the conditions of NE-3221.5(d), a fatigue analysis shall be made in accordance with NE-3221.5(e) or a fatigue test shall be made in accordance with Appendix II-1200.

(b) *Peak Stress Intensity.* This stress intensity is derived from the highest value at any point across the thickness of a section of the combination of all primary, secondary, and peak stresses produced by specified service pressures and other mechanical loads, and by

Page 72

Page 73

Page 74

Page 75

general and local thermal effects associated with Service Conditions, and including the effects of gross and local structural discontinuities.

NOTES:

- (1) The symbols P_m , P_t , Q , and F do not represent single quantities, but sets of six quantities representing the six stress components σ_x , σ_y , σ_z , τ_{xy} , τ_{yz} , and τ_{zx} .
- (2) When the secondary stress is due to a temperature transient at the point at which the stresses are being analyzed, the value of S_m shall be taken as the average of the tabulated S_m values for the highest and the lowest temperatures of the metal during the transient. When part or all of the secondary stress is due to mechanical load, the value of S_m shall not exceed the value for the highest temperature of metal during the transient.
- (3) Special rules for exceeding $3 S_m$ are provided in NE-3228.3.
- (4) The stresses in category Q are those parts of the total stress that are produced by thermal gradients, structural discontinuities, and they do not include the primary stresses that may also exist at the same point. However, it should be noted that a detailed stress analysis frequently gives the combination of primary and secondary stresses directly and, when appropriate, the calculated value represents the total of $P_m + P_t + Q$ and not Q alone. Similarly, if the stress in category F is produced by a stress concentration, the quantity F is the additional stress produced by the notch over and above the nominal stress. For example, if a point has a nominal stress intensity P_m and has a notch with a stress concentration factor K , then $P_m \leq S_m$, $P_t = Q = F = P_m (K-1)$, and the peak stress intensity equals $P_m + P_t (K-1) = K P_m$. However, P_t is the total membrane stress that results from mechanical loads, including discontinuity effects, rather than a stress increment. Therefore, the P_t value always includes the P_m contribution.
- (5) S_t is obtained from the fatigue curves, Figs. 1-9-0. The allowable stress intensity for the full range of fluctuations is $2 S_t$.
- (6) Value shown is for a solid rectangular section. See NE-3221.3(d) for other than a solid rectangular section.

* Evaluation not required for level C Service limits.

FIG. NE-3221-2 STRESS CATEGORIES AND LIMITS OF STRESS INTENSITY FOR LEVEL A AND B SERVICE LIMITS; AND FOR LEVEL C SERVICE LIMITS WHERE THE STRUCTURE IS NOT INTEGRAL AND CONTINUOUS

FIG. NE-3221-2 STRESS CATEGORIES AND LIMITS OF STRESS INTENSITY FOR LEVEL A AND B SERVICE LIMITS; AND FOR LEVEL C SERVICE LIMITS WHERE THE STRUCTURE IS NOT INTEGRAL AND CONTINUOUS

NOTES:

- (1) The symbols P_m , P_L , and P_b do not represent single quantities, but sets of six quantities representing the six stress components σ_{xx} , σ_{yy} , τ_{xy} , τ_{yz} , τ_{zx} , τ_{xy} .
- (2) Values shown are for a solid rectangular section. See NE-3221.3(d) for other than a solid rectangular section.
- (3) Values shown are applicable when $P_L \leq 0.67S_y$. When $P_L > 0.67S_y$, use the larger of the two limits,

$$[2.5 - 1.5 (P_L / S_y)] 1.2S_{mc}$$

or

$$[2.5 - 1.5 (P_L / S_y)] S_y$$

*Use greater of values specified

FIG. NE-3221-3 STRESS CATEGORIES AND LIMITS OF STRESS INTENSITY FOR LEVEL C SERVICE LIMITS WHERE THE STRUCTURE IS INTEGRAL AND CONTINUOUS; AND FOR LEVEL D SERVICE LIMITS WHERE THE STRUCTURE IS NOT INTEGRAL AND CONTINUOUS, AND AT PARTIAL PENETRATION WELDS

FIG. NE-3221-4 STRESS CATEGORIES AND LIMITS OF STRESS INTENSITY FOR LEVEL D SERVICE LIMITS WHERE THE STRUCTURE IS INTEGRAL AND CONTINUOUS

FIG. NE-3221-4 STRESS CATEGORIES AND LIMITS OF STRESS INTENSITY FOR LEVEL D SERVICE LIMITS WHERE THE STRUCTURE IS INTEGRAL AND CONTINUOUS

(c) *Conditions and Procedures.* The conditions and procedures of NE-3221.5(e) are based on a comparison of peak stress intensities with strain cycling fatigue data. The strain cycling fatigue data are represented by design fatigue strength curves of Figs. I-9.0. These curves show the allowable amplitude S_a of the alternating stress intensity component (one-half of the alternating stress intensity range) plotted against the number of cycles. This stress intensity amplitude is calculated on the assumption of elastic behavior and, hence, has the dimensions of stress, but it does not represent a real

stress when the elastic range is exceeded. The fatigue curves are obtained from uniaxial strain cycling data in which the imposed strains have been multiplied by the elastic modulus and a design margin has been provided so as to make the calculated stress intensity amplitude and the allowable stress intensity amplitude directly comparable. The curves have been adjusted, where necessary, to include the maximum effects of mean stress, which is the condition where the stress fluctuates about a mean value which is different from zero. As a consequence of this procedure, it is essential that the requirements of NE-3221.4 be satisfied at all times with transient stresses included, and that the calculated value of the alternating stress intensity be proportional to the actual strain amplitude. To evaluate the effect of alternating stresses of varying amplitudes, a linear damage relation is assumed in NE-2221(e)(4).

(d) *Vessels Not Requiring Analysis for Cyclic Service.* An analysis for cyclic service is not required, and it may be assumed that the limits on peak stress intensities as governed by fatigue have been satisfied for a vessel by compliance with the applicable requirements for construction in this Subsection, provided the specified Service Loadings of the vessel or portion thereof meet all the conditions stipulated in (1) through (6) below.

(1) *Atmospheric-to-Service Pressure Cycle.* The specified number of times (including startup and shutdown) that the pressure will be cycled from atmospheric pressure to service pressure and back to atmospheric pressure during service does not exceed the number of cycles on the applicable fatigue curve of Figs. I-9.0 corresponding to an S_a value of 3 times the S_{m1} value for the material at service temperature.

(2) *Normal Service Pressure Fluctuation.* The specified full range of pressure fluctuations during service does not exceed the quantity $(1/3) \times \text{Design Pressure} \times (S_a/S_{m1})$ where S_a is the value obtained from the applicable design fatigue curve for the total specified number of significant pressure fluctuations and S_{m1} is the allowable stress intensity for the material at service temperature. If the total specified number of significant pressure fluctuations exceeds the maximum number of cycles defined on the applicable design fatigue curve, the S_a value corresponding to the maximum number of cycles defined on the curve may be used. Significant pressure fluctuations are those for which the total excursion exceeds the quantity:

$$\text{Design Pressure} \times \frac{1}{3} \times \frac{S}{S_{m1}}$$

where S is defined as follows:

(a) if the total specified number of service cycles is 10^6 cycles or less, S is the value of S_a obtained from the applicable design fatigue curve for 10^6 cycles;

(b) if the total specified number of service cycles exceeds 10^6 cycles, S is the value of S_a obtained from the applicable design fatigue curve for the maximum number of cycles defined on the curve.

(3) *Temperature Difference - Startup and Shutdown.* The temperature difference in °F between any two adjacent points⁶ of the vessel during service does not exceed $S_a/2E\alpha$, where S_a is the value obtained from the applicable design

fatigue curves for the specified number of startup-shutdown cycles, α is the value of the instantaneous coefficient of thermal expansion and E is the value of Young's Modulus at the mean value of the temperatures at the two points as given by Section II, Part D, Subpart 2, Tables TE and TM.

(4) Temperature Difference - Similar Material. The temperature difference in °F between any two adjacent points⁶ does not change⁷ during service by more than the quantity $S_d/(2E\alpha)$, where S_d is the value obtained from the applicable design fatigue curve of Figs. I-9.0 for the total specified number of significant temperature difference fluctuations. A temperature difference fluctuation shall be considered to be significant if its total algebraic range exceeds the quantity $S/E\alpha$, where S is defined as follows.

⁶ Adjacent points are defined as follows.

(a) For surface temperature differences:

(1) on surfaces of revolution in the meridional direction, adjacent points are defined as points which are less than the distance $2\sqrt{Rt}$, where R is the radius measured normal to the surface from the axis of rotation to the mid-wall and t is the thickness of the part at the point under consideration. If the product of Rt varies, the average value of the points shall be used;

(2) on surfaces of revolution in the circumferential direction, and on flat parts such as flanges and flat heads, adjacent points are defined as any two points on the same surface.

(b) For through-thickness temperature differences, adjacent points are defined as any two points on a line normal to any surface.

⁷ The algebraic range of the difference shall be used.

Page 76

(a) If the total specified number of service cycles is 10^6 cycles or less, S is the value of S_d obtained from the applicable design fatigue curve for 10^6 cycles.

(b) If the total specified number of service cycles exceeds 10^6 cycles, S is the value of S_d obtained from the applicable design fatigue curve for the maximum number of cycles defined on the curve.

(5) Temperature Difference - Dissimilar Materials. For components fabricated from materials of differing moduli of elasticity or coefficients of thermal expansion, the total algebraic range of temperature fluctuation in °F experienced by the component during service does not exceed the magnitude $S_d/2(E_1\alpha_1 - E_2\alpha_2)$, where S_d is the value obtained from the applicable design fatigue curve for the total specified number of significant temperature fluctuations, E_1 and E_2 are the moduli of elasticity, and α_1 and α_2 are the values of the instantaneous coefficients of thermal expansion at the mean temperature value involved for the two materials of construction (Section II, Part D, Subpart 2, Tables TE and TM). A temperature fluctuation shall be considered to be significant if its total excursion exceeds the quantity $S/2(E_1\alpha_1 - E_2\alpha_2)$, where S is defined as follows:

(a) If the total specified number of service cycles is 10^6 cycles or less, S is the value of S_d obtained from the applicable design fatigue curve for 10^6 cycles.

(b) If the total specified number of service cycles exceeds 10^6 cycles, S is the value of S_d obtained from the applicable design fatigue curve for the maximum number of cycles defined on the curve. If the two materials used have different applicable design fatigue curves, the lower value of S_d shall be used in applying the rules of this paragraph.

(6) Mechanical Loads. The specified full range of mechanical loads, excluding pressure but including pipe reactions, does not result in load stress intensities whose range exceeds the S_d value obtained from the applicable design fatigue curve of Figs. I-9.0 for the total specified number of significant load fluctuations. If the total specified number of significant load fluctuations exceeds the maximum number of cycles defined on the applicable design fatigue curve, the S_d value corresponding to the maximum number of cycles defined on the curve may be used. A load fluctuation shall be considered to be significant if the total excursion of load stress exceeds the quantity S , where S is defined as follows.

(a) If the total specified number of service cycles is 10^6 cycles or less, S is the value of S_d obtained from the applicable design fatigue curve for 10^6 cycles.

(b) If the total specified number of service cycles exceeds 10^6 cycles, S is the value of S_d obtained from the applicable design fatigue curve for the maximum number of cycles defined on the curve.

(e) Procedure for Analysis for Cyclic Loading. If the specified service loadings for the vessel do not meet the

conditions of NE-3221.5(d), the ability of the vessel to withstand the specified cyclic service without fatigue failure shall be determined as provided herein. The determination shall be made on the basis of the stresses at a point, and the allowable stress cycles shall be adequate for the specified service loadings at every point. Only the stress differences due to service cycles as specified in the Design Specifications need be considered. Compliance with these requirements means only that the component is suitable from the standpoint of possible fatigue failure; complete suitability for the specified Service Loadings is also dependent on meeting the general stress limits of NE-3221 and any applicable special stress limits of NE-3227.

(1) *Stress Differences.* For each condition of specified service, determine the stress differences and the alternating stress intensity S_a in accordance with NE-3216.

(2) *Local Structural Discontinuities.* These effects shall be evaluated for all Service Loadings using stress concentration factors determined from theoretical, experimental, or photoelastic studies, or stress analysis techniques. Experimentally determined fatigue strength reduction factors may be used when determined in accordance with the procedures of Appendix II-1600, except for high strength alloy steel bolting for which the requirements of NE-3232.3 (c) shall apply when using the design fatigue curve of Fig. I-9.4. Except for the case of crack-like defects, no fatigue strength reduction factor greater than 5 need be used.

(3) *Design Fatigue Curves.* Figures I-9.0 contain the applicable fatigue design curves for the materials permitted by this Subsection. When more than one curve is presented for a given material, the applicability of each curve to materials of various strength levels is identified. Linear interpolation may be used for intermediate strength levels of these materials. As used herein, the strength level is the specified minimum room temperature value.

(4) *Effect of Elastic Modulus.* Multiply S_{alt} (as determined in NE-3216.1 or NE-3216.2) by the ratio of the modulus of elasticity given on the design fatigue curve to the value of the modulus of elasticity used in the analysis. Enter the applicable design fatigue curve of Figs. I-9.0 at this value on the ordinate axis and find the corresponding number of cycles on the abscissa. If the service cycle being considered is the only one which produces significant fluctuating stresses, this is the allowable number of cycles.

Page 77

(5) *Cumulative Damage.* If there are two or more types of stress cycles which produce significant stresses, their cumulative effect shall be evaluated as stipulated in Steps (1) through (6) below.

Step 1: Designate the specified number of times each type of stress cycle of types 1, 2, 3, ..., n will be repeated during the life of the component as $n_1, n_2, n_3, \dots, n_n$ respectively.

NOTE: In determining $n_1, n_2, n_3, \dots, n_n$, consideration shall be given to the superposition of cycles of various origins which produce a total stress difference range greater than the stress difference ranges of the individual cycles. For example, if one type of stress cycle produces 1000 cycles of a stress difference variation from zero to +60,000 psi and another type of stress cycle produces 10,000 cycles of a stress difference variation from zero to -50,000 psi, the two types of cycle to be considered are defined by the following parameters:

$$\begin{aligned} \text{Type 1 cycle: } n_1 &= 1000, \\ S_{alt1} &= (60,000 + 50,000)/2 = 55,000 \text{ psi} \\ \text{Type 2 cycle: } n_2 &= 9000, \\ S_{alt2} &= (50,000 + 0)/2 = 25,000 \text{ psi} \end{aligned}$$

Step 2: For each type of stress cycle, determine the alternating stress intensity S_{alt} by the procedures of NE-3216.1 or NE-3216.2 above. Call these quantities $S_{alt1}, S_{alt2}, S_{alt3}, \dots, S_{altn}$.

Step 3: For each value $S_{alt1}, S_{alt2}, S_{alt3}, \dots, S_{altn}$, use the applicable design fatigue curve to determine the maximum number of repetitions which would be allowable if this type of cycle were the only one acting. Call these values $N_1, N_2, N_3, \dots, N_n$.

Step 4: For each type of stress cycle, calculate the usage factors $U_1, U_2, U_3, \dots, U_n$ from $U_1 = n_1/N_1, U_2 = n_2/N_2, U_3 = n_3/N_3, \dots, U = n/N$.

Step 5: Calculate the cumulative usage factor U from $U = U_1 + U_2 + U_3 + \dots + U_n$.

Step 6: The cumulative usage factor U shall not exceed 1.0.

[98]

NE-3221.6 Thermal Stress Ratchet.

It should be noted that under certain combinations of steady state and cyclic loadings there is a possibility of large distortions developing as the result of ratchet action; that is, the deformation increases by a nearly equal amount for each cycle. Examples of this phenomenon are treated in this subparagraph and in NE-3227.3.

(a) The limiting value of the maximum cyclic thermal stress permitted in a portion of an axisymmetric shell loaded by steady state internal pressure in order to prevent cyclic growth in diameter is as follows. Let:

y'	= maximum allowable range of thermal stress computed on an elastic basis divided by the yield strength ⁸ S_y
x	= maximum general membrane stress due to pressure divided by the yield strength ⁸ S_y

Case 1: Linear variation of temperature through the wall:

$$y' = 1/x \text{ for } 0 < x < 0.5$$

$$y' = 4(1 - x) \text{ for } 0.5 < x < 1.0$$

Case 2: Parabolic constantly increasing or constantly decreasing variation of temperature through the wall:

$$y' = 5.2(1 - x) \text{ for } 0.615 < x < 1.0$$

and approximately for $x < 0.615$ as follows:

$$y' = 4.65, 3.55, \text{ and } 2.70 \text{ for } x = 0.3, 0.4, \text{ and } 0.5, \text{ respectively.}$$

(b) Use of yield strength S_y in the above relations instead of the proportional limit allows a small amount of growth during each cycle until strain hardening raises the proportional limit to S_y . If the yield strength of the material is higher than the endurance limit⁹ for the material, the latter value shall be used if there is to be a large number of cycles because strain softening may occur.

NE-3221.7 Deformation Limits.

Any deformation limits prescribed by the Design Specifications shall be satisfied.

NE-3222 Buckling Stress Values

NE-3222.1 Basic Compressive Allowable Stress.

The maximum buckling stress values to be used for the evaluation of instability shall be either of the following:

(a) one-third the value of critical buckling stress determined by one of the methods given below:

(1) rigorous analysis which considers the effects of gross and local buckling, geometric imperfections, nonlinearities, large deformations, and inertial forces (dynamic loads only);

⁸ It is permissible to use $1.5S_{md}$ whenever it is greater than S_y .

⁹ The endurance limit shall be taken as 2 times the S_a value at 10^6 cycles in the applicable fatigue curve of Figs. I-9.0, except that for the curves of Figs. I-9.2 the endurance limit shall be taken as two times the S_a value at 10^{11} cycles obtained from Curve A.

(2) classical (linear) analysis reduced by margins which reflect the difference between theoretical and actual load

capacities;

(3) tests of physical models under conditions of restraint and loading the same as those to which the configuration is expected to be subjected;

(b) the value determined by the applicable rules of NE-3133.

NE-3222.2 Stability Stress Limits

(a) For Design Conditions and Level A and B Service Limits, the value given in NE-3222.1 shall not be exceeded.

(b) For Level C Service Limits, 120% of the value given in NE-3222.1 shall not be exceeded.

(c) For Level D Service Limits, 150% of the value given in NE-3222.1 shall not be exceeded.

[98]

NE-3226 Testing Limits

The evaluation of pressure test loadings (NCA-2142.3) shall be in accordance with (a) through (f) below.

(a) If the minimum required hydrostatic test pressure defined in NE-6221 is to be exceeded at any point in a containment vessel or appurtenance by more than 6%, the maximum permissible hydrostatic test pressure shall be established by the engineer responsible for the Design Report using an analysis which includes all loadings which may exist during the test. The calculated primary general membrane stress intensity P_m shall not exceed 90% of the tabulated yield strength S_y at the test temperature. For solid rectangular sections, the primary membrane plus primary bending stress intensity $P_m + P_b$ shall not exceed the applicable limits given in (1) or (2) below:

(1) For $P_m \leq 0.67S_y$:

$$P_m + P_b \leq 1.35S_y$$

(2) For $0.67S_y < P_m \leq 0.90S_y$:

$$P_m + P_b \leq (2.15S_y - 1.2P_m)$$

where S_y is the tabulated yield strength at test temperature.

For other than solid rectangular sections, $P_m + P_b$ shall not exceed a value of α times $0.9S_y$, where the factor α is defined as the ratio of the load set producing a fully plastic section divided by the load set producing initial yielding in the extreme fibers of the section.

(b) The maximum permissible pneumatic test pressure of a completed vessel or appurtenance shall not exceed that value which results in a calculated primary general membrane stress intensity P_m of 75% of the tabulated yield strength at the test temperature. For solid rectangular sections, the primary membrane plus primary bending stress intensity $P_m + P_b$ shall not exceed 115% of the tabulated yield strength S_y at the test temperature. For other than solid rectangular sections, $P_m + P_b$ shall not exceed a value of α times $0.75S_y$, where the factor α is defined as the ratio of the load set producing a fully plastic section divided by the load set producing initial yielding in the extreme fibers of the section.

(c) In the evaluation of the initial yield and fully plastic section capacities in (a) and (b) above, the ratio of each individual load in the respective load set to each other load in that load set shall be the same as the respective ratios of the individual loads in the specified design load set. The value of α shall not exceed the value calculated for bending only ($P_m = 0$). In no case shall the value of α exceed 1.5. The propensity for buckling of the part of the section that is in compression shall be investigated.

(d) In multichamber vessels, pressure may be simultaneously applied to the appropriate adjacent chamber to meet the stress limits in (a) and (b) above.

(e) External pressure shall not exceed 125% of the value determined by the rules of NE-3222.

(f) The number of hydrostatic tests in accordance with NE-6220, pneumatic tests in accordance with NE-6320, or any

combination of such tests, shall not exceed ten unless a fatigue evaluation is made when required by NE-3221.5. In this fatigue evaluation, the limits on primary plus secondary stress intensity range (NE-3221.4) may be taken as the larger of $3S_{m1}$ or $2S_y$, when at least one extreme of the stress intensity range is determined by the test loadings.
[98]

NE-3227 Special Stress Limits

The following stress limits are provided to cover special conditions or configurations. Some of these limits are more restrictive and some less restrictive than the stress intensity limits of NE-3221. In cases of conflict between these requirements and those of NE-3221, the rules of NE-3227 take precedence. The rules of NE-3227 shall apply to Design Loadings and Level A and B Service Loadings. These rules shall also apply to Level C and D Service Loadings unless otherwise justified in the Design Report.

NE-3227.1 Bearing Loads

(a) The average bearing stress for resistance to crushing under the maximum load, experienced as a result

Page 79

of Design Loadings or of any of the service or testing loadings, shall be limited to S_y at temperature, except that when the distance to a free edge is larger than the distance over which the bearing load is applied, a stress of $1.5S_y$ at temperature is permitted. For clad surfaces, the yield strength of the base metal may be used if, when calculating the bearing stress, the bearing area is taken as the lesser of the actual contact area or the area of the base metal supporting the contact surface.

(b) When bearing loads are applied near free edges, such as at a protruding ledge, the possibility of a shear failure shall be considered. In the case of load stress only (NE-3213.12), the average shear stress shall be limited to $0.6S_{mc}$. In the case of load stress plus secondary stress (NE-3213.9), the average shear stress shall not exceed (1) or (2) below:

(1) for materials to which Note (2) of Section II, Part D, Subpart 1, Tables 1A and 1B applies, the lower of $0.5S_y$ at 100°F (38°C) and $0.675S_y$ at temperature;

(2) for all other materials, $0.5S_y$ at temperature.

(c) For clad surfaces, if the configuration or thickness is such that a shear failure could occur entirely within the clad material, the allowable shear stress for the cladding shall be determined from the properties of the equivalent wrought material. If the configuration is such that a shear failure could occur across a path that is partially base metal and partially clad material, the allowable shear stresses for each material shall be used when evaluating the combined resistance to this type of failure.

(d) When considering bearing stresses in pins and similar members, the S_y at temperature value is applicable, except that a value of $1.5S_y$ may be used if no credit is given to bearing area within one pin diameter from a plate edge.

NE-3227.2 Pure Shear

(a) The average primary shear stress across a section loaded in pure shear experienced as a result of Design Loadings (for example, keys, shear rings, screw threads) shall be limited to $0.6S_{mc}$.

(b) The maximum primary shear experienced as a result of Design Loadings shall be limited to $0.8S_{mc}$.

NE-3227.3 Progressive Distortion of Nonintegral Connections.

Screw-on caps, screwed-in plugs, shear-ring closures, and breech-lock closures are examples of nonintegral connections which are subject to failure by bell mouting or other types of progressive deformation. If any combination of applied loads produces yielding, such joints are subject to ratcheting because the mating members may become loose at the end of each complete service cycle and start the next cycle in a new relationship with each other, with or without manual manipulation. Additional distortion may occur in each cycle so that interlocking parts, such as threads, can eventually lose engagement. Therefore, primary plus secondary stress intensities (NE-3221.4) which result in slippage between the parts of a nonintegral connection in which disengagement could occur as a result of progressive distortion shall be limited to the value S_y (Section II, Part D, Subpart 2, Table Y-1).

NE-3227.4 Triaxial Stresses.

The algebraic sum of the three primary principal stresses ($\sigma_1 + \sigma_2 + \sigma_3$) shall not exceed four times the tabulated value of S_{mc} .

NE-3227.5 Nozzle Piping Transition.

Within the limits of reinforcement given by NE-3334, whether or not nozzle reinforcement is provided, the P_m classification is applicable to stress intensities resulting from pressure induced general membrane stresses as well as stresses, other than discontinuity stresses, due to external loads and moments including those attributable to restrained free end displacements of the attached pipe. Also, within the limits of reinforcement, a P_L classification shall be applied to local primary membrane stress intensities derived from discontinuity effects plus primary bending stress intensities due to combined pressure and external loads and moments including those attributable to restrained free end displacements of the attached pipe; and a $P_L + P_b + Q$ classification shall apply to primary plus secondary stress intensities resulting from a combination of pressure, temperature, and external loads and moments including those due to restrained free end displacements of the attached pipe. Beyond the limits of reinforcement, a P_m classification is applicable to stress intensities resulting from pressure induced general membrane stresses as well as the average stress across the nozzle thickness due to externally applied nozzle axial, shear, and torsional loads other than those attributable to restrained free end displacement

Page 80

of the attached pipe may also be excluded. The range of membrane plus bending stress intensity attributable solely to the restrained free end displacements of the attached piping shall be $\leq 3S_{ml}$. The nozzle, outside the reinforcement limit, shall not be thinner than the larger of the pipe thickness or the quantity $t_p(S_{mp}/S_{mn})$ where t_p is the nominal thickness of the mating pipe, S_{mp} is the allowable stress intensity value for the pipe material, and S_{mn} is the allowable stress intensity value for the nozzle material.

NE-3227.6 Applications of Elastic Analysis for Stresses Beyond the Yield Strength.

Certain of the allowable stresses permitted in the criteria are such that the maximum stress calculated on an elastic basis may exceed the yield strength of the material. The limit on primary plus secondary stress intensity of $3S_{ml}$ (NE-3221.4) has been placed at a level which assures shakedown to elastic action after a few repetitions of the stress cycle, except in regions containing significant local structural discontinuities or local thermal stresses. These last two factors are considered only in the performance of a fatigue evaluation. Therefore, the procedures of (a) and (b) below shall be used.

(a) In evaluating stresses for comparison with the stress limits on other than fatigue allowables, stresses shall be calculated on an elastic basis.

(b) In evaluating stresses for comparison with fatigue allowables, all stresses except those which result from local thermal stresses [NE-3213.13(b)] shall be evaluated on an elastic basis. In evaluating local thermal stresses, the elastic equations shall be used, except that the numerical value substituted for Poisson's ratio shall be determined from the expression:

$$\nu = 0.5 - 0.2 \frac{S_y}{S_a} \text{ but not less than } 0.3$$

where

S_y

= the yield strength of the material at the mean value of the temperature of the cycle

S_a

= the value obtained from the applicable design fatigue curve (Figs. I-9.0) for the specified number of cycles of the condition being considered

NE-3228 Applications of Plastic Analysis

The following subparagraphs provide guidance in the application of plastic analysis and some relaxation of the stress limits of NE-3221 which are allowed if plastic analysis is used.

NE-3228.1 Plastic Analysis.

The limits on local membrane stress intensity (NE-3221.2), primary plus secondary stress intensity (NE-3221.4), thermal stress ratchet in shell (NE-3221.6), and progressive distortion of nonintegral connections (NE-3227.3) need not be satisfied at a specific location if, at the location, the procedures of (a) through (c) below are used.

(a) In evaluating stresses for comparison with the remaining stress limits, the stresses are calculated on an elastic basis.

(b) In lieu of satisfying the specific requirements of NE-3221.2, NE-3221.4, NE-3221.6, and NE-3227.3 at a specific location, the structural action is calculated on a plastic basis and the design shall be considered to be acceptable if shakedown occurs (as opposed to continuing deformation) and if the deformations which occur prior to shakedown do not exceed specified limits.

(c) In evaluating stresses for comparison with fatigue allowables, the numerically maximum principal total strain range which occurs after shakedown shall be multiplied by one-half of the modulus of elasticity of the material (Section II, Part D, Subpart 2, Table TM) at the mean value of the temperature of the cycle.

NE-3228.2 Limit Analysis.

The limits on local membrane stress intensity (NE-3221.2) and primary membrane plus primary bending stress intensity (NE-3221.3) need not be satisfied at a specific location if it can be shown by means of limit analysis or by tests that the specified loadings do not exceed two-thirds of the lower bound collapse load except for those materials of Section II, Part D, Subpart 1, Tables 2A and 2B to which Note (2) of those tables is applicable. For these latter materials the specified loading shall not exceed the product of the applicable permanent strain limiting factor of Section II, Part D, Subpart 2, Table Y-2 times the lower bound collapse load.

NE-3228.3 Simplified Elastic-Plastic Analysis.

The $3S_{m1}$ limit on the range of primary plus secondary stress intensity (NE-3221.4) may be exceeded provided the requirements of (a) through (f) below are met.

(a) The range of primary plus secondary membrane plus bending stress intensity, excluding thermal bending stresses, shall be $\leq 3S_{m1}$.

(b) The value of S_n used for entering the design fatigue curve is multiplied by the factor K_e where:

$$\begin{aligned} K_e &= 1.0, \text{ for } S_n \leq 3S_{m1} \\ &= 1.0 + [(1 - n)/n(m - 1)][(S_n/3S_{m1}) - 1], \text{ for } 3S_{m1} < S_n < 3mS_{m1} \\ &= 1/n, \text{ for } S_n \geq 3mS_{m1} \\ S_n &= \text{range of primary plus secondary stress intensity} \end{aligned}$$

**TABLE NE-3228.3(b)-1
VALUES OF m , n , AND $T_{\max}$ FOR VARIOUS
CLASSES OF PERMITTED MATERIALS**

Materials	m	n	$T_{\max}$, °F
Low alloy steel	2.0	0.2	700
Martensitic stainless steel	2.0	0.2	700
Carbon steel	3.0	0.2	700
Austenitic stainless steel	1.7	0.3	800
Nickel-Chromium-Iron	1.7	0.3	800
Nickel-Copper	1.7	0.3	800

TABLE NE-3228.3(b)-1 VALUES OF m , n , AND $T_{\max}$ FOR VARIOUS CLASSES OF PERMITTED MATERIALS

The values of the material parameters m and n are given for the various classes of materials in Table NE-3228.3(b)-1.

(c) The rest of the fatigue evaluation stays the same as required in NE-3221.5, except that the procedure of NE-3227.6 need not be used.

(d) The component meets the thermal ratcheting requirement of NE-3221.6.

(e) The temperature does not exceed those listed in Table NE-3228.3(b)-1 for the various classes of materials.

(f) The material shall have a specified minimum yield strength to specified minimum tensile strength ratio of less than 0.80.

NE-3228.4

NE-3228.4 Impulse Loads.

A plastic analysis or test may be used to justify relaxation of the Level A, Level B, Level C, and Level D Service Limits given in NE-3221.1, NE-3221.2, NE-3221.3, and NE-3221.4 if the applied loading is impulsive in nature. The plastic analysis or test shall demonstrate that the factor against failure under the applied impulsive loading is not less than the factor against failure provided by Level A Service Limits for sustained loads. This demonstration shall be included in the Design Report for review by the Owner or the Owner's designee for acceptability to the regulatory authority having jurisdiction at the nuclear power plant site.

NE-3230 STRESS LIMITS FOR BOLTS

NE-3231 Design Conditions

(a) The number and cross-sectional area of bolts required to resist the Design Pressure shall be determined in accordance with the procedures of Appendix XI, using the larger of the bolt loads given by the equations of Appendix XI as a Design Mechanical Load. The allowable bolt design stresses shall be 1.1 times the values given in Section II, Part D, Subpart 1, Table 3 for bolting materials.

(b) When sealing is effected by a seal weld instead of a gasket, the gasket factor m and the minimum design seating stress y may be taken as zero.

(c) When gaskets are used for preservice testing only, the design is satisfactory if the above requirements are satisfied for $m = y = 0$.

NE-3232 Combined Loads

Actual service stresses in bolts, such as those produced by the combination of preload, pressure, and differential thermal expansion, may be higher than the allowable stresses given in NE-3231(a).

NE-3232.1 Average Stress.

The maximum value of service stress, averaged across the bolt cross section and neglecting stress concentrations, shall not exceed 2.2 times the stress values of Section II, Part D, Subpart 1, Table 3.

NE-3232.2 Maximum Stress.

The maximum value of service stress, except as restricted by NE-3232.3, at the periphery of the bolt cross section resulting from direct tension plus bending and neglecting stress concentrations shall not exceed 3.3 times the stress values of Section II, Part D, Subpart 1, Table 3. Stress intensity, rather than maximum stress, shall be limited to this value when the bolts are tightened by methods other than heaters, stretchers, or other means which minimize residual torsion.

NE-3232.3 Fatigue Analysis of Bolts.

Unless the components on which they are installed meet all the conditions of NE-3221.5(d) and thus require no fatigue analysis, the suitability of bolts for cyclic service shall be determined in accordance with the procedures of (a) through (e) below.

(a) *Bolting Having Less Than 100.0 ksi (689 MPa) Tensile Strength.* Bolts made of materials which have specified minimum tensile strengths of less than 100.0 ksi (689 MPa) shall be evaluated for cyclic service by the methods of NE-3221.5(e) using the applicable design fatigue curve of Fig. I-9.4 and an appropriate fatigue strength reduction factor [NE-3232.3(c)].

(b) *High Strength Alloy Steel Bolting.* High strength alloy steel bolts and studs may be evaluated for cyclic service by the methods of NE-3221.5(e) using the design fatigue curve of Fig. I-9.4, provided the requirements of (1), (2), and (3) below are met.

(1) The maximum value of the service stress (NE-3232.2) at the periphery of the bolt cross section (resulting from direct tension plus bending) and neglecting

stress concentration shall not exceed $2.7S_{ml}$, if the higher of the two fatigue design curves given in Fig. I-9.4 is used. The $2S_{ml}$ limit for direct tension is unchanged.

(2) Threads shall be of a V-type having a minimum thread root radius no smaller than 0.003 in. (0.08 mm).

(3) Fillet radii at the end of the shank shall be such that the ratio of fillet radius to shank diameter is not less than 0.060.

(c) *Fatigue Strength Reduction Factor (NE-3213.17)*. Unless it can be shown by analysis or tests that a lower value is appropriate, the fatigue strength reduction factor used in the fatigue evaluation of threaded members shall not be less than 4.0. However, when applying the rules of NE-3232.3(b) for high strength alloy steel bolts, the value used shall not be less than 4.

(d) *Effect of Elastic Modulus*. Multiply S_{alt} (as determined in NE-3216.1 or NE-3216.2) by the ratio of the modulus of elasticity given on the design fatigue curve to the value of the modulus of elasticity used in the analysis. Enter the applicable design fatigue curve at this value on the ordinate axis and find the corresponding numbers of cycles on the abscissa. If the service cycle being considered is the only one which produces significant fluctuating stresses, this is the allowable number of cycles.

(e) *Cumulative Damage*. The bolts shall be acceptable for the specified cyclic application of loads and thermal stresses provided the cumulative usage factor U as determined in NE-3221(e)(5) does not exceed 1.0.

NE-3236 Design Stress Values

The design stress intensity values S_{mc} and allowable stress values S are 1.1 times the values given in Section II, Part D, Subpart 1, Table 3 for bolting. Values for intermediate temperatures may be found by interpolation. The basis for establishing stress values is given in Appendix III.

NE-3300 DESIGN BY FORMULA

NE-3310 DESIGN CRITERIA

NE-3311 Requirements for Acceptability

10 For the purpose of this provision, substantial loads are defined as those which cumulatively result in stresses which exceed 10% of the primary stresses induced by the Design Pressure, such stresses being defined as maximum principal stresses.

Rules are provided in this Subarticle for Design Loadings and Levels A and B Service Loadings which do not include substantial¹⁰ mechanical or thermal loads other than pressure. The design shall be such that the rules of this Subarticle are satisfied for any configurations and loadings explicitly treated.

(a) The allowable stress value at temperature S is 1.1 times that tabulated in Section II, Part D, Subpart 1, Tables 1A and 1B and is to be used.

NE-3320 DESIGN CONSIDERATIONS

NE-3324 Vessels Under Internal Pressure

NE-3324.1 General Requirements.

Equations are given in this paragraph for determining the minimum thicknesses under internal pressure loading in cylindrical and spherical shells and ellipsoidal, conical, and hemispherical heads.

NE-3324.2 Nomenclature.

The symbols used in Fig. NE-3324.2-1 are defined as follows:

t = minimum required thickness of shell or head, after forming,

	exclusive of corrosion allowance, in.
P	= Design Pressure, psi
R	= inside radius of the shell course under consideration before corrosion allowance is added, in.
R_o	= outside radius of the shell course under consideration, in.
S	= maximum allowable stress value, psi
D	= inside diameter of the head skirt; or inside length of the major axis of an ellipsoidal head; or inside diameter of a conical head at the point under consideration, measured perpendicular to the longitudinal axis, in.
D_o	= outside diameter of the head skirt; or outside length of the major axis of an ellipsoidal head; or outside diameter of a conical head at the point under consideration, measured perpendicular to the longitudinal axis, in.
D_1	= inside diameter of the conical portion of a toriconical head at its point of tangency to the knuckle, measured perpendicular to the axis of the cone, in.
L	= inside spherical or crown radius for torispherical and hemispherical heads, in.
L	= $K_1 D$ for ellipsoidal heads in which K_1 is obtained from Table NE-3332.2-1, in.
L_o	= outside spherical or crown radius, in.
r	= inside knuckle radius, in.
h	= one-half of the length of the minor axis of the ellipsoidal head or the inside depth of the ellipsoidal head measured from the tangent line head bend line, in.
K	= a factor in the equations for ellipsoidal heads depending on the head proportion $D/2h$ (Table NE-3324.2-1)

FIG. NE-3324.2-1 PRINCIPAL DIMENSIONS OF TYPICAL HEADS

FIG. NE-3324.2-1 PRINCIPAL DIMENSIONS OF TYPICAL HEADS

$D/2h$

= ratio of the major to the minor axis of ellipsoidal heads, which equals the inside diameter of the skirt of the head divided by twice the inside height of the head and is used in Table NE-3324.2-1

α

= one-half of the included apex angle of the cone at the center line of the head

TABLE NE-3324.2-1 VALUES OF FACTOR K

NE-3324.3 Cylindrical Shells.

The minimum thickness of cylindrical shells shall be the greater thickness as given by (a) through (d) below.

(a) *Circumferential Stress (Longitudinal Joints)*. When the thickness does not exceed one-half of the inside radius, or P does not exceed $0.385S$, the following equations shall apply:

$$t = \frac{PR}{S - 0.6P} \quad \text{or} \quad P = \frac{St}{R + 0.6t}$$

(b) *Longitudinal Stress (Circumferential Joints)*. When the thickness does not exceed one-half of the inside radius, or P does not exceed $1.25S$, the following equations shall apply:

$$t = \frac{PR}{2S + 0.4P} \quad \text{or} \quad P = \frac{2St}{R - 0.4t}$$

Page 84

(c) *Thickness of Cylindrical Shells*. The following equations, in terms of the outside radius, are equivalent to and may be used instead of those given in (a) above:

$$t = \frac{(PR_o)}{S + 0.4P} \quad \text{or} \quad P = \frac{St}{(R_o - 0.4t)}$$

(d) *Thick Cylindrical Shells*

(1) *Circumferential Stress (Longitudinal Joints)*. When the thickness of the cylindrical shell under internal pressure exceeds one-half of the inside radius, or when P exceeds $0.385S$, the following equations shall apply.

When P is known and t is desired:

$$t = R (Z^{1/2} - 1) = R_o \frac{(Z^{1/2} - 1)}{Z^{1/2}}$$

where

$$Z = \frac{S + P}{S - P}$$

When t is known and P is desired:

$$P = S \left(\frac{Z - 1}{Z + 1} \right)$$

where

$$Z = \left(\frac{R + t}{R} \right)^2 = \left(\frac{R_o}{R} \right)^2 = \left(\frac{R_o}{R_o - t} \right)^2$$

(2) *Longitudinal Stress (Circumferential Joints)*. When the thickness of the cylindrical shell under internal pressure exceeds one-half of the inside radius, or when P exceeds $1.25S$, the following equations shall apply.

When P is known and t is desired:

$$t = R (Z^{1/2} - 1) = R_o \frac{(Z^{1/2} - 1)}{Z^{1/2}}$$

where

$$Z = \left(\frac{P}{S} + 1 \right)$$

When t is known and P is desired:

$$P = S(Z - 1)$$

where

$$Z = \left(\frac{R + t}{R} \right)^2 = \left(\frac{R_o}{R} \right)^2 = \left(\frac{R_o}{R_o - t} \right)^2$$

NE-3324.4 Spherical Shells

(a) When the thickness of the shell of a spherical vessel does not exceed $0.356R$, or P does not exceed $0.665S$, the following equations shall apply. Any reduction in thickness within a shell course of a spherical shell shall be in accordance with NE-3361.

$$t = \frac{PR}{2S - 0.2P} \quad \text{or} \quad P = \frac{2St}{R + 0.2t}$$

(b) The following equations, in terms of the outside radius, are equivalent to and may be used instead of those given in (a) above:

$$t = \frac{PR_o}{2S + 0.8P}$$

$$P = \frac{2St}{R_o - 0.8t}$$

(c) When the thickness of the shell of a spherical vessel or of a hemispherical head under internal pressure exceeds $0.356R$, or when P exceeds $0.665S$, the following equations shall apply.

When P is known and t is desired:

$$t = R (Y^{1/3} - 1) = R_o \left(\frac{Y^{1/3} - 1}{Y^{1/3}} \right)$$

where

$$Y = \frac{2(S + P)}{2S - P}$$

When t is known and P is desired:

$$P = 2S \left(\frac{Y - 1}{Y + 2} \right)$$

where

$$Y = \left(\frac{R + t}{R} \right)^3 = \left(\frac{R_o}{R_o - t} \right)^3$$

NE-3324.5 Formed Heads, General Requirements.

Formed heads shall meet the requirements of (a) through (f) below.

(a) All formed heads, thicker than the shell and concave to pressure, for butt welded attachment, shall have a skirt length sufficient to meet the requirements of Fig. NE-3358.1(a)-1 when a tapered transition is required.

(b) Any taper at a welded joint within a formed head shall be in accordance with NE-3361. The taper at a circumferential welded joint connecting a formed head to a main shell shall meet the requirements of NE-3358 for the respective type of joint shown therein.

(c) All formed heads concave to pressure and for butt welded attachment need not have an integral skirt when the thickness of the head is equal to or less than the thickness of the shell. When a skirt is provided, its thickness shall be at least that required for a seamless shell of the same diameter.

(d) The inside crown radius to which a head is dished shall not be greater than the outside diameter of the skirt of the head. The inside knuckle radius of a torispherical head shall not be less than 6% of the outside diameter of the skirt of the head but in no case less than three times the head thickness.

(e) If a torispherical, ellipsoidal, or hemispherical head is formed with a flattened spot or surface, the diameter of the flat spot shall not exceed that permitted for flat heads as given by Eq. (1) or (2) of NE-3325.2 using $C = 0.25$.

(f) Openings in formed heads under internal pressure shall comply with the requirements of NE-3330.

NE-3324.6 Ellipsoidal Heads

(a) *Ellipsoidal Heads.* The required thickness of a dished head of semiellipsoidal form, in which one-half the minor axis, inside depth of the head minus the skirt, equals one-fourth the inside diameter of the head skirt, shall be determined by:

$$t = \frac{PD}{2S - 0.2P} \quad \text{or} \quad P = \frac{2St}{D + 0.2t}$$

(b) *Ellipsoidal Heads of Other Ratios.* The minimum required thickness of an ellipsoidal head of other than a 2:1 ratio shall be determined by:

$$t = \frac{PDK}{2S - 0.2P} \quad \text{or} \quad P = \frac{2St}{KD + 0.2t}$$

$$t = \frac{PD_o K}{2S + 2P(K - 0.1)} \quad \text{or} \quad P = \frac{2St}{KD_o - 2t(K - 0.1)}$$

where

$$K = \frac{1}{6} \left[2 + \left(\frac{D}{2h} \right)^2 \right]$$

Numerical values of the factor K are given in Table NE-3324.2-1.

NE-3324.7 Hemispherical Heads

(a) When the thickness of a hemispherical head does not exceed $0.356L$ or P does not exceed $0.665S$, the following equations shall apply:

$$t = \frac{PL}{2S - 0.2P} \quad \text{or} \quad P = \frac{2St}{L + 0.2t}$$

(b) When the thickness of the hemispherical head under internal pressure exceeds $0.356L$, or when P exceeds $0.665S$, the following equations shall apply:

$$t = L(Y^{1/3} - 1) = L_o \left(\frac{Y^{1/3} - 1}{Y^{1/3}} \right)$$

where

$$Y = \frac{2(S + P)}{2S - P}$$

or

$$P = 2S \left(\frac{Y - 1}{Y + 2} \right)$$

where

$$Y = \left(\frac{L + t}{L} \right)^3 = \left(\frac{L_o}{L_o - t} \right)^3$$

NE-3324.8 Torispherical Heads

(a) *Torispherical Heads With a 6% Knuckle Radius.* The required thickness of a torispherical head in which the knuckle radius is 6% of the inside crown radius shall be determined by:

$$t = \frac{0.885PL}{S - 0.1P} \quad \text{or} \quad P = \frac{St}{0.885L + 0.1t}$$

(b) *Torispherical Heads of Other Proportions.* The required thickness of a torispherical head in which the knuckle radius is other than 6% of the crown radius shall be determined by:

Page 86

$$t = \frac{PLM}{2S - 0.2P} \quad \text{or} \quad P = \frac{2St}{LM + 0.2t}$$

$$t = \frac{PL_oM}{2S + P(M - 0.2)}$$

TABLE NE-3324.8(b)-1

											1.77

NOTE:

(1) Maximum ratio allowed by NE-3324.5(d) when L equals the outside diameter of the skirt of the head.

TABLE NE-3324.8(b)-1 VALUES OF FACTOR M

or

$$P = \frac{2St}{ML_o - t(M - 0.2)}$$

where

$$M = \frac{1}{4} \left(3 + \sqrt{\frac{L}{r}} \right)$$

Numerical values of the factor M are given in Table NE-3324.8(b)-1.

(c) Torispherical heads made of materials having a specified minimum tensile strength exceeding 80 ksi (552 MPa) shall be designed using a value of S equal to 22 ksi (152 MPa) at room temperature and reduced in proportion to the ratio of the reduction in maximum allowable stress values from room temperature to design temperature for the material as shown in Section II, Part D, Subpart 1, Tables 1A and 1B.

NE-3324.9 Conical Heads Without Transition Knuckle.

The required thickness of conical heads or conical shell sections that have a half apex angle α not greater than 30 deg shall be determined by:

$$t = \frac{PD}{2 \cos \alpha (S - 0.6P)} \quad \text{or} \quad P = \frac{2St \cos \alpha}{D + 1.2t \cos \alpha}$$

For α greater than 30 deg, see NE-3324.11(b)(5). A compression ring shall be provided when required by the rule in NE-3324.11(b).

NE-3324.10 Toriconical Heads.

Toriconical heads in which the inside knuckle radius is neither less than 6% of the outside diameter of the head skirt nor less than three times the knuckle thickness shall be used when the angle α exceeds 30 deg except when the design complies with NE-3324.11. The required thickness of the knuckle shall be determined by the first equation of NE-3324.8 (b) in which:

$$L = \frac{D_1}{2 \cos \alpha}$$

The required thickness of the conical portion shall be determined by the equation in NE-3324.9, using D_1 in place of D .

NE-3324.11 Reducer Sections

(a) General Requirements

(1) The rules of NE-3324.11(a) apply to concentric reducer sections.

(2) The symbols used are defined as follows:

D_1	= inside diameter of reducer section at point of tangency to the knuckle or reverse curve, in.
A	= required area of reinforcement, sq in.
A_e	= effective area of reinforcement, due to excess metal thickness, sq in.
Δ	= value to indicate need for reinforcement at cone-to-cylinder intersection having a half-apex angle $\alpha \leq 30$ deg. When $\Delta \geq \alpha$, no reinforcement at the junction is required [Table NE-3324.11(b)(2)-1 and Table NE-3324.11(b)(3)-1].
m	= the lesser of

$$\left[\frac{t_s}{t} \cos (\alpha - \Delta) \right]$$

or

$$\left[\frac{t_c \cos \alpha \cos (\alpha - \Delta)}{t} \right]$$

R_L

= inside radius of larger cylinder, in.

R_s

= inside radius of smaller cylinder, in.

r_L

= inside radius of knuckle at larger cylinder, in.

r_s

= radius to the inside surface of flare at the small end, in.

t_s

= nominal thickness of cylinder at cone-to-cylinder junction, exclusive of corrosion allowance, in.

t_c

= nominal thickness of cone at cone-to-cylinder junction,

exclusive of corrosion allowance, in.

$$t_e = \text{the smaller of } (t_s - t) \text{ or } [t_c - (t/\cos \alpha)], \text{ in.}$$

(3) The thickness of each element of a reducer, as defined in (4) below, under internal pressure shall not be less than that computed by the applicable equation.

(4) A transition section reducer consisting of one or more elements may be used to join two cylindrical shell sections of different diameters but with a common axis, provided the requirements of (a) and (b) below are met.

(a) *Conical Shell Section.* The required thickness of a conical shell section or the allowable pressure for such a section of given thickness shall be determined by the equations given in NE-3324.9.

(b) *Knuckle Tangent to the Larger Cylinder.* Where a knuckle is used at the large end of a reducer section, its shape shall be that of a portion of an ellipsoidal, hemispherical, or torispherical head. The thickness and other dimensions shall satisfy the requirements.

(5) When elements of (4) above having different thicknesses are combined to form a reducer, the joints, including the plate taper required by NE-3361, shall lie entirely within the limits of the thinner element being joined.

(6) A reducer may be a simple conical shell section [Fig. NE-3324.11(a)(6)-1 sketch (a)] without knuckle, provided the half apex angle α is not greater than 30 deg, except as provided for in (b) below. A reinforcement ring shall be provided at either or both ends of the reducer when required by (b) below.

(7) A toriconical reducer [Fig. NE-3324.11 (a)(6)-1 sketch (b)] may be shaped as a portion of a toriconical shell, a portion of a hemispherical head plus a conical section, or a portion of an ellipsoidal head plus a conical section, provided the half apex angle α is not greater than 30 deg, except as provided for in (b) below. A reinforcement ring shall be provided at the small end of a conical reducer element when required by (b) below.

(8) Reverse curve reducers [Fig. NE-3324.11 (a)(6)-1 sketches (c) and (d)] may be shaped of elements other than those illustrated.

(b) Supplementary Requirements for Reducer Sections and Conical Heads Under Internal Pressure

(1) The equations of (2) and (3) below provide for the design of reinforcement, if needed, at the cone-to-cylinder junctions for reducer sections and conical heads where all the elements have a common axis and the half apex angle $\alpha \leq 30$ deg. In (5) below, provision is made for special analysis in the design of cone-to-cylinder intersections with or without reinforcing rings where α is greater than 30 deg.

(2) Reinforcement shall be provided at the junction of the cone with the large cylinder for conical heads and reducers without knuckles when the value of Δ obtained from Table NE-3324.11(b)(2)-1, using the appropriate ratio P/S , is less than α . Interpolation may be made in the table.

(a) The cross-sectional area of the reinforcement ring shall be at least equal to that indicated by the following equation:

$$A = \frac{PR_L^2}{2S} \left(1 - \frac{\Delta}{\alpha} \right) \tan \alpha$$

(b) When the thickness, less corrosion allowance, of both the reducer and cylinder exceeds that required by the applicable design equations, the minimum excess thickness may be considered to contribute to the required reinforcement ring in accordance with the following equation:

$$A_e = 4t_e \sqrt{R_L t_s}$$

(c) Any additional area of reinforcement which is required shall be situated within a distance of $\sqrt{R_L t_s}$ from the junction of the reducer and the cylinder. The centroid of the added area shall be within a distance of $\sqrt{0.5 R_L t_s}$ from the junction.

(3) Reinforcement shall be provided at the junction of the conical shell of a reducer without a flare and the small cylinder when the value of Δ obtained from Table NE-3324.11(b)(3)-1, using the appropriate ratio P/S , is less than α .

Page 88

GENERAL NOTES:

- (1) r_L shall not be less than the smaller of $0.12 (R_L + t)$ or $3t$
- (2) r_s has no dimensional requirement

FIG. NE-3324.11(a)(6)-1 LARGE HEAD OPENINGS: REVERSE CURVE AND CONICAL SHELL REDUCER SECTIONS

NOTE:

(1) $\Delta = 30$ deg for greater values of P/S .

TABLE NE-3324.11(b)(3)-1 VALUES OF Δ FOR JUNCTIONS AT THE SMALL CYLINDER FOR $\alpha \leq 30$ deg

(a) The cross-sectional area of the reinforcement ring shall be at least equal to that indicated by the following formula:

$$A = \frac{PR_s^2}{2S} \left(1 - \frac{\Delta}{\alpha} \right) \tan \alpha$$

(b) When the thickness, less corrosion allowance, of either the reducer or cylinder exceeds that required by the applicable design equation, the excess thickness may be considered to contribute to the required reinforcement ring in accordance with the following equation:

$$A_e = m \sqrt{R_s t} [t_c - (t/\cos \alpha) + (t_s - t)]$$

(c) Any additional area of reinforcement which is required shall be situated within a distance of $\sqrt{R_s t_s}$ from the junction, and the centroid of the added area shall be within a distance of $0.5\sqrt{R_s t_s}$ from the junction.

(4) Reducers not described in NE-3324.11(a)(3), such as those made up of two or more conical frustums having different slopes, may be designed in accordance with (5) below.

(5) When the half apex angle α is greater than 30 deg, cone-to-cylinder junctions without a knuckle

Page 89

may be used, with or without reinforcing rings, if the design is based on stress analysis. When a stress analysis is made, the calculated stresses shall be evaluated in accordance with NE-3200.

NE-3324.12 Nozzles

(a) The wall thickness of a nozzle or other connection shall not be less than the nominal thickness of the connecting piping. In addition, the wall thickness shall not be less than the thickness computed for the applicable loadings in NE-3111 plus the thickness added for corrosion. Except for access openings and openings for inspection only, the wall thickness shall not be less than the smaller of (1) and (2) below:

(1) the required thickness of the shell or head to which the connection is attached plus the corrosion allowance provided in the shell or head adjacent to the connection;

(2) the minimum thickness¹¹ of standard wall pipe plus the corrosion allowance on the connection; for nozzles larger than the largest pipe size included in ANSI B36.10, the wall thickness of that largest size plus corrosion allowance.

(b) The allowable stress value for shear in a nozzle neck shall be 70% of the allowable tensile stress for the vessel material.

NE-3325 Flat Heads and Covers

The minimum thickness of unstayed flat heads, cover plates, and blind flanges shall conform to the requirements given in this paragraph. These requirements apply to circular heads and covers. Some acceptable types of flat heads and covers are shown in Fig. NE-3325-1. In this figure the dimensions of the component parts and the dimensions of the welds are exclusive of extra metal required for corrosion allowance.

NE-3325.1 Nomenclature.

The symbols used are defined as follows:

C	= a factor depending upon the method of attachment of head, shell dimensions, and other items as listed in NE-3325.3, dimensionless
d	= diameter, measured as indicated in Fig. NE-3325-1, in.
h_G	= gasket moment arm, equal to the radial distance from the center line of the bolts to the line of the gasket reaction, as shown in Table XI-3221.2-2, in.
l	= length of flange of flanged heads, measured from the tangent line of knuckle, as indicated in Fig. NE-3325-1 sketches (a) and (c), in.
m	= the ratio t_r/t_s
P	= Design Pressure, psi
r	= inside corner radius on a head formed by flanging or

¹¹ The minimum thickness for all pipe materials is the nominal wall thickness listed in Table 2 of ANSI B36.10, less 12 $\frac{1}{2}$ %. For diameters other than those listed in the table, this shall be based on the next largest pipe size.

	forging, in.
S	= maximum allowable stress, psi, from Section II, Part D, Subpart 1, Tables 1A and 1B, times 1.1
t	= minimum required thickness of flat head or cover, exclusive of corrosion allowance, in.
t_f	= actual thickness of the flange on a forged head, at the large end, exclusive of corrosion allowance, as indicated in Fig. NE-3325-1 sketches (b-1) and (b-2), in.
t_h	= actual thickness of flat head or cover, exclusive of corrosion allowance, in.
t_p	= the smallest dimension from the face of the head to the edge of the weld preparation, in.
t_r	= required thickness of shell, for pressure, in.
t_s	= actual thickness of shell, exclusive of corrosion allowance, in.
t_w	= thickness through the weld joining the edge of a head to the inside of a vessel, as indicated in Fig. NE-3325-1 sketch (f), in.
t_1	= throat dimension of the closure weld, as indicated in Fig. NE-3325-1 sketch (p), in.
W	= total bolt load, lb, given for circular heads for Eqs. (3) and (4), XI-3223

NE-3325.2 Thickness.

The thickness of flat unstayed heads, covers, and blind flanges shall conform to one of the following two requirements.
12

(a) Circular blind flanges of ferrous materials conforming to ANSI B16.5 shall be acceptable for the diameters and pressure temperature ratings in Tables 2 to 8 of that Standard, when of the types shown in Fig. NE-3325-1 sketches (j) and (k).

(b) The minimum required thickness of flat unstayed circular heads, covers, and blind flanges shall be calculated by the formula:

$$(1) t = d \sqrt{CP/S}$$

12 The formulas provide safe construction as far as stress is concerned. Greater thickness may be necessary if deflection would cause leakage at threaded or gasketed joints.

except when the head, cover, or blind flange is attached by bolts causing an edge moment [Fig. NE-3325-1 sketch (n)], in which case the thickness shall be calculated by:

FIG. NE-3325-1 SOME ACCEPTABLE TYPES OF UNSTAYED FLAT HEADS AND COVERS

FIG. NE-3325-1 SOME ACCEPTABLE TYPES OF UNSTAYED FLAT HEADS AND COVERS

$$(2) t = d \sqrt{CP/S + 1.27 W h_G / S d^3}$$

When using Eq. (2), the thickness t shall be calculated for both Service Loadings and gasket seating, and the greater of the two values shall be used. For Service Loadings, the value of P shall be the Design Pressure, and the values of S at the Design Temperature and W from Formula (3) of XI-3223 shall be used. For gasket seating, P equals zero, and the values of S at atmospheric temperature and W from Eq. (4) of XI-3223 shall be used.

[98]

NE-3325.3 Values of C .

For the types of construction shown in Fig. NE-3325-1 and Fig. NE-4243.1-1, the minimum values of C to be used in Eqs. (1) and (2) shall be as given in (a) through (l) below for Fig. NE-3325-1 and in (m) below for Fig. NE-4243.1-1.

(a) In sketch (a), $C = 0.17$ for flanged circular heads forged integral with or butt welded to the vessel with an inside corner radius not less than three times the required head thickness, with no special requirement with regard to length of flange.

(1) $C = 0.10$ for circular heads, when the flange length for heads of the above design is not less than:

$$l = \left[1.1 - 0.8 \frac{t_s^2}{t_h^2} \right] \sqrt{d t_h} \quad (3)$$

(3)

(2) $C = 0.10$ for circular heads, when the flange length l is less than the requirement in Eq. (3) but the shell thickness is not less than:

$$t_s = 1.12 t_h \sqrt{1.1 - l / \sqrt{d t_h}} \quad (4)$$

(4)

for a length of at least $2\sqrt{d t_s}$.

(3) When $C = 0.10$ is used, the taper shall be 1:4.

(b) In sketch (b-1), $C = 0.17$ for forged circular heads integral with or butt welded to the vessel, where the flange thickness is not less than two times the shell thickness, the corner radius on the inside is not less than three times the flange thickness and the welding meets all the requirements of NE-4000.

(c) In sketch (b-2), $C = 0.33m$ but not less than 0.3 for forged circular heads integral with or butt welded to the vessel,

where the flange thickness is not less than the shell thickness and the corner radius on the inside is not less than 1.5 times the flange thickness. [See Fig. NE-4243.1-1 sketches (a) and (b) for the special case where $t_f = t_s$.]

(d) In sketch (c), $C = 0.13$ for integral flat circular heads when the dimension d does not exceed 24 in., the ratio of thickness of the head to the dimension d is not less than 0.05 nor greater than 0.25, the head thickness t_h is not less than the shell thickness t_s , the inside corner radius is not less than $0.25t_s$, and the construction is obtained by special techniques of upsetting and spinning the end of the shell, such as employed in closing header ends.

(e) In sketches (d), (e), and (f), $C = 0.33m$ but not less than 0.3 for circular plates welded to the inside of a vessel and otherwise meeting the requirements for the respective types of welded vessels. If a value of m less than 1 is used in calculating t , the shell thickness t_s shall be maintained along a distance inwardly from the inside face of the head equal to at least $2\sqrt{dt_s}$. The throat thickness of the fillet welds in sketch (e) shall be at least $0.7t_s$. The size of the weld t_w in sketch (f) shall not be less than two times the required thickness of a seamless shell nor less than 1.25 times the nominal shell thickness but need not be greater than the head thickness; the weld shall be deposited in a welding groove with the root of the weld at the inner face of the head as shown in the figure.

(f) In sketch (g), $C = 0.33$ for circular plates welded to the end of the shell when t_s is at least $1.25t_r$ and the weld details conform to the requirements of NE-3358.3(e) and Fig. NE-4243-1 sketches (a) through (g).

(g) In sketch (h), $C = 0.33m$ but not less than 0.3 for circular plates if an inside fillet weld with minimum throat thickness of $0.7t_s$ is used and the details of the outside weld conform to the requirements of NE-3358.3(c) and Fig. NE-4243-1 sketches (a) through (g), in which the inside weld can be considered to contribute an amount equal to t_s to the sum of the dimensions a and b .

(h) In sketches (i) and (j), $C = 0.2$ for circular heads and covers bolted to the vessel as indicated in the figures. Note that Eq. (2) shall be used because of the extra moment applied to the cover by the bolting. When the cover plate is grooved for a peripheral gasket as shown in sketch (j), the net cover plate thickness under the groove or between the groove and the outer edge of the cover plate shall not be less than $d\sqrt{1.27Wh_G/Sd^3}$ for circular heads and covers.

(i) In sketches (k), (l), and (m), $C = 0.2$ for a circular plate inserted into the end of a vessel and held in place by a positive mechanical locking arrangement, and when all possible means of failure (either by shear, tension, compression, or radial deformation, including flaring, resulting from pressure and differential thermal expansion) are resisted using stresses consistent with this Article. Seal welding may be used, if desired.

(j) In sketch (n), $C = 0.17$ for circular covers, bolted with a full-face gasket, to shells, flanges, or side plates.

Page 92

(k) In sketch (o), $C = 0.50$ for circular plates screwed into the end of a vessel having an inside diameter d not exceeding 12 in. (305 mm), or for heads having an integral flange screwed over the end of a vessel having an inside diameter d not exceeding 12 in. (305 mm), and when the design of the threaded joint against failure by shear, tension, compression, or radial deformation, including flaring resulting from pressure and differential thermal expansion, is based on stresses consistent with this Article. Seal welding may be used.

(l) In sketch (p), $C = 0.33$ for circular plates having a dimension d not exceeding 18 in. (457 mm) inserted into the vessel as shown and otherwise meeting the requirements for the respective types of welded vessels. The end of the vessel shall be crimped over at least 30 deg but not more than 45 deg. The throat of the weld shall not be less than the thickness of the flat head or shell, whichever is greater.

(m) In Fig. NE-4243.1-1, $C = 0.33m$ but not less than 0.3 when the dimensional requirements of NE-3358.4 are met. [98]

NE-3326 Spherically Dished Covers With Bolting Flanges

NE-3326.1 Nomenclature.

The symbols used are defined as follows:

t	= minimum required thickness of head plate after forming, in.
L	= inside spherical or crown radius, in.
r	= inside knuckle radius, in.
P	= Design Pressure, psi
S	= maximum allowable stress value, psi
T	= flange thickness, in.
M_o	= the total moment, in.-lb, determined as in XI-3230 for heads concave to pressure, and XI-3260 for heads convex to pressure; except that for heads of the type shown in Fig. NE-3326.1-1 sketch (d), H_D and h_D shall be as defined below, and an additional moment $H_r h_r$ ¹³ shall be included
H_r	= radial component of the membrane load in the spherical segment = $H_D \cot \beta_1$, lb, acting at the intersection of the inside of the flange ring with the center line of the dished cover thickness
h_r	= lever arm of H_r about centroid of flange ring, in.

¹³ Since $H_r h_r$ in some cases will subtract from the total moment, the moment in the flange ring when the internal pressure is zero may be the determining loading for the flange design.

H_D	= axial component of the membrane load in the spherical segment, lb, acting at the inside of the flange ring = $0.785B^2P$
h_D	= radial distance from the bolt circle to the inside of the flange ring, in.
β_1	= angle formed by the tangent to the center line of the dished cover thickness at its point of intersection with the flange ring, and a line perpendicular to the axis of the dished cover, where

$$\beta = \arcsin \left(\frac{B}{2L + t} \right)$$

A	= outside diameter of flange, in.
B	= inside diameter of flange, in.
C	= bolt circle diameter, in.

[98]

NE-3326.2 Spherically Dished Heads With Bolting Flanges.

Circular spherically dished heads with bolting flanges, both concave and convex to the pressure and conforming to the several types illustrated in Fig. NE-3326.1-1, shall be designed in accordance with the requirements of (a) through (d) below. For heads convex to pressure, the spherical segments shall be thickened, if necessary, to meet the requirements of NE-3133. The actual value of the total moment M may calculate to be either plus or minus for both the heads concave to

pressure and the heads convex to pressure. However, for use in all of the formulas which follow, the absolute values for both P and M_o shall be used.

(a) Heads of the type shown in Fig. NE-3326.1-1 sketch (a):

(1) the thickness of the head t shall be determined by the appropriate equation in NE-3324;

(2) the head radius L or the knuckle radius r shall not exceed the limitations given in NE-3324;

(3) the flange shall comply with at least the requirements of Fig. XI-3120-1 and shall be designed in accordance with the applicable provisions of Appendix XI; within the range of ANSI B16.5, the flange facings and drillings should conform to those Standards and the thickness specified therein shall be considered as a minimum requirement.

(b) Heads of the type shown in Fig. NE-3326.1-1 sketch (b):

(1) head thickness t :

$$t = \frac{5PL}{6S} \quad (5)$$

(5)

(2) flange thickness T :

for ring gasket:

$$T = \sqrt{\frac{M_o}{SB} \left[\frac{A + B}{A - B} \right]} \quad (6)$$

(6)

FIG. NE-3326.1-1 SPHERICALLY DISHED COVERS WITH BOLTING FLANGES

FIG. NE-3326.1-1 SPHERICALLY DISHED COVERS WITH BOLTING FLANGES

for full-faced gasket:

$$T = 0.6 \sqrt{\frac{P}{S} \left[\frac{B(A + B)(C - B)}{A - B} \right]} \quad (7)$$

(7)

NOTE: The radial components of the membrane load in the spherical segment are assumed to be resisted by its flange.

Within the range of ANSI B16.5, the flange facings and drillings should conform to those Standards, and the thickness specified therein shall be considered as a minimum requirement.

(c) Heads of the type shown in Fig. NE-3326.1-1 sketch (c):

(1) Head thickness:

$$t = \frac{5PL}{6S} \quad (8)$$

(8)

(2) Flange thickness for ring gaskets shall be calculated as follows:

(a) for heads with round bolting holes:

$$T = Q + \sqrt{\frac{1.875 M_o (C + B)}{SB(7C - 5B)}} \quad (9)$$

(9)

where

$$Q = \frac{PL}{4S} \left(\frac{C + B}{7C - 5B} \right) \quad (10)$$

(10)

(b) for heads with bolting holes slotted through the edge of the head:

$$T = Q + \sqrt{\frac{1.875 M_o (C + B)}{SB(3C - B)}} \quad (11)$$

(11)

where

Page 94

$$Q = \frac{PL}{4S} \left(\frac{C + B}{3C - B} \right) \quad (12)$$

(12)

(3) Flange thickness for full face gaskets shall be as calculated in Eq. (13):

$$T = Q + \sqrt{Q^2 + \frac{3BQ(C - B)}{L}} \quad (13)$$

(13)

The value of Q in Eq. (13) is calculated by Eq. (10) for round bolting holes or by Eq. (12) for bolting holes slotted through the edge of the head [see (c)(2) above].

(4) The required flange thickness shall be T as calculated in Eq. (6) or (7) above, but in no case less than the value of t as calculated in Eq. (5);

(d) Heads of the type shown in Fig. NE-3326.1-1 sketch (d):

(1) Head thickness t :

$$t = \frac{5PL}{6S} \quad (14)$$

(14)

(2) Flange thickness T :

$$(15) T = F + \sqrt{F^2 + J}$$

where

$$F = \frac{PB \sqrt{4L^2 - B^2}}{8S(A - B)} \quad (16)$$

(16)

$$J = \left(\frac{M_o}{SB} \right) \left(\frac{A + B}{A - B} \right) \quad (17)$$

(17)

NOTE: These equations are approximate in that they do not take into account continuity between the flange ring and the dished head. A more exact method of analysis which takes this into account may be used if it meets the requirements of NE-3200. Such a method may parallel the method of analysis and allowable stresses for flange design in Appendix XI.

[98]

NE-3327 Quick Actuating Closures

Closures other than the multibolted type designed to provide access to the contents space of a component shall have the locking mechanism or locking device so designed that failure of any one locking element or component in the locking mechanism cannot result in the failure of all other locking elements and the release of the closure. Quick actuating closures shall be so designed and installed that it may be determined by visual external observation that the holding elements are in good condition and that their locking elements, when the closure is in the closed position, are in full engagement.

NE-3327.1 Positive Locking Devices.

Quick actuating closures that are held in position by positive locking devices and that are fully released by partial rotation or limited movement of the closure itself or the locking mechanism, and any closure that is other than manually operated, shall be so designed that when the vessel is installed the conditions of (a) through (c) below are met.

(a) The closure and its holding elements are fully engaged in their intended operating position before pressure can be built up in the vessel.

(b) Pressure tending to force the closure clear of the vessel will be released before the closure can be fully opened for access.

(c) In the event that compliance with (a) and (b) above is not inherent in the design of the closure and its holding elements, provision shall be made so that devices to accomplish this can be added when the vessel is installed.

NE-3327.2 Other Quick Access and Safety Devices.

It is recognized that it is impractical to write detailed requirements to cover the multiplicity of devices used for quick access, or to prevent negligent operation or the circumventing of safety devices. Any device or devices which will provide the safeguards broadly described in NE-3327.1 will meet the intent of this Subsection.

NE-3327.3 Manual Operation.

Quick actuating closures that are held in position by a locking device or mechanism that requires manual operation and are so designed that there will be leakage of the contents of the vessel prior to disengagement of the locking elements and release of closure need not satisfy NE-3327.1, but such closures shall be equipped with an audible or visible warning device that will serve to warn the operator if pressure is applied to the vessel before the closure and its holding elements are fully engaged in their intended position and, further, will serve to warn the operator if an attempt is made to operate the locking mechanism or device before the pressure within the vessel is released.

NE-3327.4 Pressure Indicating Device.

When installed, all vessels having quick actuating closures shall be provided with a pressure indicating device visible from the operating area.

Page 95

NE-3328 Combination Units

When a pressure vessel unit consists of more than one independent pressure chamber, operating at the same or different pressures and temperatures, each such chamber shall be designed and constructed to withstand the most severe condition of coincident pressure and temperature expected in normal service. Only the parts of chambers which come within the scope of this Subsection need be constructed in compliance with its provisions.

NE-3330 OPENINGS AND REINFORCEMENT

NE-3331 General Requirements for Openings

(a) For vessels or parts thereof which are not in cyclic service, analysis showing satisfaction of the requirements of NE-3221.1, NE-3221.2, and NE-3221.3, and NE-3221.4 in the immediate vicinity of the openings is not required for pressure loading if the rules of NE-3330 are met.

(b) For vessels or parts thereof which are in cyclic service and do not meet the requirements of NE-3221.5(d) for the specified Service Loads so that a fatigue analysis is required, the rules contained in NE-3330 assure that the stresses resulting from pressure load satisfy only the requirements of NE-3221.1, NE-3221.2, and NE-3221.3 in the vicinity of openings, and no specific analysis showing satisfaction of those stress limits is required. The requirements of NE-3221.4 may also be considered to be satisfied if, in the vicinity of the nozzle, the stress intensity resulting from external nozzle loads and thermal effects, including gross but not local structural discontinuities, is shown by analysis to be less than $1.5S_m$. In this case, when evaluating the requirements of NE-3221.5(e), the peak stress intensities resulting from pressure loadings may be obtained by application of the stress index method of NE-3338.

(c) The provisions of (a) and (b) above are not intended to restrict the design to any specified section thicknesses or other design details, provided the basic stress limits are satisfied. If it is shown by analysis that all the stress requirements have been met, the rules of NE-3330 are waived.

(d) Openings shall be circular, elliptical, or of any other shape which results from the intersection of a circular or elliptical cylinder with a vessel.

(e) Properly reinforced openings in cylindrical and spherical shells are not limited as to size. Rules regarding metal available for reinforcement are given in NE-3335.

(f) All references to dimensions apply to the finished dimensions, excluding material added as corrosion allowance.

(g) Openings may be located in welded joints.

NE-3332 Reinforcement Requirements for Openings in Shells and Formed Heads

NE-3332.1 Openings Not Requiring Reinforcement.

Reinforcement shall be provided in amount and distribution such that the requirements for area of reinforcement are satisfied for all planes through the center of the opening and normal to the surface of the vessel, except that single circular openings need not be provided with reinforcement if the openings have diameters equal to or less than $2\frac{1}{2}$ in. (64 mm).

NE-3332.2 Required Area of Reinforcement.

The total cross-sectional area of reinforcement A required in any given plane for a vessel under internal pressure shall not be less than:

$$A = dt_r F$$

where

d	= finished diameter of a circular opening or finished dimension (chord length) of an opening on the plane being considered for elliptical and obround openings in corroded condition, in.
F	= a correction factor which compensates for the variation in pressure stresses on different planes with respect to the axis of a vessel. (A value of 1.00 shall be used for all configurations, except that Fig. NE-3332.2-1 may be used for integrally reinforced openings in cylindrical shells and cones.)
t_r	= the required thickness of a shell or head computed by the rules of this Article for the Design Pressure, in., except as given in (a), (b), and (c) below:

(a) when the opening and its reinforcement are entirely within the spherical portion of a torispherical head, t_r is the thickness required by NE-3324.8(b) using $M = 1$;

(b) when the opening is in a cone, t is the thickness required for a seamless cone of diameter D measured where the

nozzle axis pierces the inside wall of the cone;

(c) when the opening and its reinforcement are in an ellipsoidal head and are located entirely within a circle, the center of which coincides

Page 96

with the center of the head and the diameter of which is equal to 80% of the shell diameter, t_r is the thickness required for a seamless sphere of radius $K_1 D$, where D is the shell diameter and K_1 is given by Table NE-3332.2-1.

**FIG. NE-3332.2-1 CHART FOR DETERMINING
VALUES OF F**

FIG. NE-3332.2-1 CHART FOR DETERMINING VALUES OF F

At least one-half of the required reinforcing shall be on each side of the center line of the opening.

NE-3332.4 Reinforcement for External Pressure.

The reinforcement required for openings in vessels designed for external pressure need only be 50% of that required in the formula for area in NE-3332.2, except that t_r is the wall thickness required by the rules for components under external pressure.

NE-3332.5 Reinforcement for Both Internal and External Pressure.

Reinforcement of vessels subject to both internal and external pressures shall meet the requirements of NE-3332.2 for internal pressure and of NE-3332.4 for external pressure.

TABLE NE-3332.2-1
VALUES OF SPHERICAL RADIUS FACTOR K_1
Equivalent Spherical Radius = $K_1 D$; $D/2h$ = Axis Ratio.
Interpolation Permitted for Intermediate Values.

$D/2h$		3.0	2.8	2.6	2.4	2.2
K_1		1.36	1.27	1.18	1.08	0.99
$K/2h$	2.0	1.8	1.6	1.4	1.2	1.0
K_1	0.90	0.81	0.73	0.65	0.57	0.50

TABLE NE-3332.2-1 VALUES OF SPHERICAL RADIUS FACTOR K_1

NE-3333 Reinforcement Required for Openings in Flat Heads

(a) Flat heads that have an opening with a diameter that does not exceed one-half of the head diameter shall have a total cross-sectional area of reinforcement not less than that given by the formula:

$$A = 0.5dt_r$$

where d is as defined in NE-3332.2 and t_r is the thickness in inches which meets the requirements of NE-3325 in the absence of the opening.

(b) As an alternative to (a) above, the thickness of flat heads may be increased to provide the necessary opening reinforcement as follows:

(1) in Eq. (1) of NE-3325.2, by using $2C$ or 0.75 in place of C , whichever is less;

(2) in Eq. (2) of NE-3325.2, by doubling the quantity under the square root sign.

NE-3334 Limits of Reinforcement

The boundaries of the cross-sectional area in any plane normal to the vessel wall and passing through the center of the opening and within which metal shall be located in order to have value as reinforcement are designated as the limits of reinforcement for that plane and are given in the following subparagraphs.

NE-3334.1 Limit of Reinforcement Along the Vessel Wall.

The limits of reinforcement, measured along the midsurface of the nominal wall thickness, shall meet the following.

(a) One hundred percent of the required reinforcement shall be within a distance on each side of the axis of the opening equal to the greater of the following:

(1) the diameter of the finished opening in the corroded condition;

(2) the radius of the finished opening in the corroded condition plus the sum of the thicknesses of the vessel wall and the nozzle wall.

(b) Two-thirds of the required reinforcement shall be within a distance on each side of the axis of the opening equal to the greater of the following:

(1) $r + 0.5\sqrt{R}t$, where R is the mean radius of shell or head, t is the nominal vessel wall thickness, and r is the radius of the finished opening in the corroded condition;

(2) the radius of the finished opening in the corroded condition plus two-thirds the sum of the thicknesses of the vessel wall and the nozzle wall.

NE-3334.2 Limit of Reinforcement Normal to the Vessel Wall.

The limits of reinforcement, measured normal to the vessel wall, shall conform to the contour of the surface at a distance from each surface equal to the following limits as shown in Fig. NE-3334.2-1 and specified in (a), (b), and (c) below.

(a) For Fig. NE-3334.2-1 sketches (a), (b), (d), and (e):

$$\text{limit of reinforcement} = 0.5 \sqrt{r_m^2 - t_n^2} + 0.5r_2$$

where

$$r_m = \text{mean radius} = r_i + 0.5t_n$$

$$r_i = \text{inside radius, in.}$$

$$t_n = \text{nominal nozzle thickness, as indicated, in.}$$

$$r_2 = \text{transition radius between nozzle and wall, in.}$$

For the case of a nozzle with a tapered inside diameter, the limit shall be obtained by using r_i and t_n values at the nominal outside diameters of the vessel wall [Fig. NE-3334.2-1 sketch (e)].

(b) For Fig. NE-3334.2-1 sketches (c) and (f):

$$\text{limit of reinforcement} = 0.5 \sqrt{r_m^2 - t_n^2}$$

where

$$r_m = r_i + 0.5 t_n$$

$$r_i = \text{inside radius, in.}$$

$$t_n = t_p + 0.667X$$

t_p	= nominal thickness of the attached pipe, in.
X	= slope offset distance, in.
θ	= angle between vertical and slope, 45 deg or less

For the case of a nozzle with a tapered inside diameter, the limit shall be obtained by using r_i and t_n values at the center of gravity of nozzle reinforcement area. These values must be determined by a trial and error procedure [Fig. NE-3334.2-1 sketch (f)].

(c) When reinforcing pads or insert plates are used, the limits of reinforcement, measured normal to the vessel wall, shall conform to the contour of the surface at a distance from each surface equal to $(0.5 \sqrt{r_m t_n} + t_e)$ or $(2.5 t_n + t_e)$, whichever is larger, where r_m is the mean nozzle radius, t_n is the nozzle thickness, and t_e is equal to the thickness of any added reinforcement or 1.5 times the vessel wall thickness, whichever is smaller.

NE-3335 Metal Available for Reinforcement

Metal may be counted as contributing to the area of reinforcing called for in NE-3332, provided it lies within the limits of reinforcement specified in NE-3334 and shall be limited to material which meets the following requirements:

- (a) metal forming a part of the vessel wall which is in excess of that required in accordance with NE-3130 and is exclusive of corrosion allowance;
- (b) similar excess metal in the nozzle wall, provided the nozzle is integral with the vessel wall or is joined to it by a full penetration weld;
- (c) weld metal which is fully continuous with the vessel wall;
- (d) the mean coefficient of thermal expansion of metal to be included as reinforcement under (b) or (c) above shall be within 15% of the value of the vessel wall material;
- (e) metal not fully continuous with the shell, as that in nozzles attached by partial penetration welds on only one side, shall not be counted as reinforcement;
- (f) metal available for reinforcement shall not be considered as applying to more than one opening;
- (g) not less than one-half the required material shall be on each side of the center line of the opening.

NE-3335.1 Reinforcement of Multiple Openings

(a) When any two openings in a group of two or more openings are spaced at less than two times their average diameter so that their limits of reinforcement overlap, the two openings shall be reinforced in the plane connecting the centers (Fig. NE-3335.1-1), in accordance with NE-3330 through NE-3336, with a combined reinforcement that has an area equal to the combined area of the reinforcements required for separate openings. No portion of the cross section is to be considered as applying to more than one opening, or to be evaluated more than once in a combined area. The following requirements shall also apply.

(1) When the distance between the centers of the openings is greater than $1\frac{1}{3}$ times their average diameter, the area of reinforcement between them shall be

not less than 50% of the total required for these openings.

FIG. NE-3334.2-1 NOZZLE DIMENSIONS

FIG. NE-3334.2-1 NOZZLE DIMENSIONS

GENERAL NOTES:

- (1) Hatched area represents overlapping of the reinforcement limits.
- (2) Each cross section indicated by a straight line a-a must be investigated for adequacy of reinforcement.
- (3) Heavy circles represent openings, and light circles represent limits of reinforcement.

FIG. NE-3335.1-1 ARRANGEMENT OF MULTIPLE OPENINGS

FIG. NE-3335.1-1 ARRANGEMENT OF MULTIPLE OPENINGS

(2) When the distance between the centers of the openings is less than $1\frac{1}{3}$ times their average diameter, no credit for reinforcement shall be taken for any of the material between these openings, and the openings shall be reinforced as described in (b) below.

(b) Any number of adjacent openings, in any arrangement, may be reinforced for an assumed opening of a diameter enclosing all such openings. The diameter of the assumed opening shall not exceed the following:

(1) for vessels 60 in. (1520 mm) diameter and less, one-half the vessel diameter, but not to exceed 20 in. (508 mm);

(2) for vessels over 60 in. (1520 mm) diameter, one-third the vessel diameter, but not to exceed 40 in. (1000 mm)

(c) When a group of openings is reinforced by a thicker section butt welded into the shell or head, the edges of the inserted section shall be tapered as prescribed in NE-3361.

NE-3336 Strength of Reinforcing Material

Material used for reinforcement shall be preferably the same as that of the vessel wall. If the material of the nozzle wall or reinforcement has a lower design stress value S than the vessel material, the amount of area provided by the nozzle wall or reinforcement in satisfying the requirements of NE-3332 shall be taken as the actual area provided multiplied by the ratio of the nozzle or reinforcement design stress value to the vessel material design stress value. No reduction in the reinforcing required may be taken for the increased strength of reinforcing material and weld metal having higher design stress values than that of the material of the vessel wall. Deposited weld metal outside of either the vessel wall or any

reinforcing pad used as reinforcement shall be credited with an allowable stress value equivalent to the weaker of the materials connected by the weld. Vessel-to-nozzle or pad-to-nozzle attachment weld metal within the vessel wall or within the pad may be credited with a stress value equal to that of the vessel wall or pad, respectively.

Page 100

NE-3336.1 Strength of Weld.

On each side of the plane defined in NE-3334, the strength of the attachment joining the vessel wall and reinforcement or any two parts of the attached reinforcement shall be at least equal to the lesser of (a) or (b) below:

- (a) the strength in tension of the cross section of the element of reinforcement being considered; or
- (b) the strength in tension of the area defined in NE-3332 less the strength in tension of the reinforcing area which is integral in the vessel wall.

NE-3336.2 Strength of Attachment.

The strength of the attachment joint shall be considered for its entire length on each side of the plane of the area of reinforcement defined in NE-3334. For obround openings, consideration shall also be given to the strength of the attachment joint on one side of the plane transverse to the parallel sides of the opening which passes through the center of the semicircular end of the opening.

NE-3338 Pressure Stresses in Openings for Fatigue Evaluation Under Operating Conditions

NE-3338.1 General.

For the purpose of determining peak stresses around the opening, three acceptable methods are listed below.

(a) *Analytical Method.* This method uses suitable analytical techniques such as finite element computer analyses, which provide detailed stress distributions around openings. In addition to peak stresses due to pressure, the effects of other loadings shall be included. The total peak stress at any given point shall be determined by combining stresses due to pressure, thermal, and external loadings in accordance with the rules of NE-3200.

(b) *Experimental Stress Analysis.* This is based on data from experiments (Appendix II).

(c) *Stress Index Method.* This uses various formulas together with available data obtained from an extensive series of tests covering a range of variation of applicable dimensional ratios and configurations (NE-3338.2). This method covers only single, isolated openings. Stress indices may also be determined by theoretical or experimental stress analysis.

[98]

NE-3338.2 Stress Index Method

(a) The term *stress index*, as used herein, is defined as the numerical ratio of the stress components σ_r , σ_n , and σ_t under consideration to the computed membrane stress in the unpenetrated vessel material. However, the material which increases the thickness of a vessel wall locally at the nozzle shall not be included in the calculations of these stress components. When the thickness of the vessel wall is increased over that required to the extent provided hereinafter, the values of r_1 and r_2 in Fig. NE-3334.2-1 shall be referred to the thickened section.

FIG. NE-3338.2-1 DIRECTION OF STRESS COMPONENTS

FIG. NE-3338.2-1 DIRECTION OF STRESS COMPONENTS

(b) The symbols for the stress components are shown in Fig. NE-3338.2-1 and are defined as follows:

σ_t	= the stress component in the plane of the section under consideration and parallel to the boundary of the section, psi
σ_n	= the stress component normal to the plane of the section (ordinarily the circumferential stress around the hole in the shell), psi
σ_r	= the stress component normal to the boundary of the section, psi
S	= the stress intensity (combined stress) at the point under consideration, psi

(c) When the conditions of (d) below are satisfied, the stress indices of Table NE-3338.2(c)-1 may be used for nozzles designed in accordance with the applicable rules of NE-3330. These stress indices deal only with the maximum stresses, at certain general locations, due to internal pressure. In the evaluation of stresses in or adjacent to vessel openings and connections, it is often necessary to consider the effect of stresses due to external loadings or thermal stresses. In such cases, the total stress at a given point may be determined by superposition. In the case of combined stresses due to internal pressure and nozzle loading, the maximum stresses for a given location should be considered as acting at the same point and added algebraically, unless positive evidence is available to the contrary.

Page 101

**TABLE NE-3338.2(c)-1
STRESS INDICES FOR NOZZLES**

Nozzles in Spherical Shells and Formed Heads		
Stress	Inside Corner	Outside Corner
σ_n	2.0	2.0
σ_t	-0.2	2.0
σ_r	$-2t_n/R$	0
S	2.2	2.0

Nozzles in Cylindrical Shells				
Stress	Longitudinal Plane		Transverse Plane	
	Inside	Outside	Inside	Outside
σ_n	3.1	1.2	1.0	2.1
σ_t	-0.2	1.0	-0.2	2.6
σ_r	$-t_n/R$	0	$-t_n/R$	0
S	3.3	1.2	1.2	2.6

TABLE NE-3338.2(c)-1 STRESS INDICES FOR NOZZLES

(d) The indices of Table NE-3338.2(c)-1 apply when the conditions stipulated in (1) through (6) below exist.

(1) The opening is for a circular nozzle whose axis is normal to the vessel wall. If the axis of the nozzle makes an angle ϕ with the normal to the vessel wall and if $d/D \leq 0.15$, an estimate of the σ_n index on the inside may be obtained

from one of the following equations.

For hillside connections in spheres or cylinders:

$$K_2 = K_1 (1 + 2 \sin^2 \varphi)$$

For lateral connections in cylinders:

$$K_2 = K_1 [1 + (\tan \varphi)^{4/3}]$$

where

K_1

= the σ_n inside stress index of Table NE-3338.2(c)-1 for a radial connection

K_2

= the estimated σ_n inside stress index for the nonradial connection

(2) The arc distance measured between the center lines of adjacent nozzles along the inside surface of the shell is not less than three times the sum of their inside radii for openings in a head or along the longitudinal axis of a shell and is not less than two times the sum of their radii for openings along the circumference of a cylindrical shell.

(3) The following dimensional ratios are met:

Ratio	Cylinder	Sphere
$\frac{\text{Inside shell diameter}}{\text{Shell thickness}} = \frac{D}{t}$	10 to 100	10 to 100
$\frac{\text{Inside nozzle diameter}}{\text{Inside shell diameter}} = \frac{d}{D}$	0.5, max.	0.5, max.
$\frac{d}{\sqrt{Dt}}$	—	0.8, max.
$d/\sqrt{Dt_n r_2/t}$	1.5, max.	—

TABLE - UNTITLED

In the case of cylindrical shells, the total nozzle reinforcement area on the transverse axis of the connections, including any outside of the reinforcement limits, shall not exceed 200% of that required for the longitudinal axis (compared to 50% permitted by Fig. NE-3332.2-1), unless a tapered transition section is incorporated into the reinforcement and the shell, meeting the requirements of NE-3361.

(4) The inside corner radius r_1 (Fig. NE-3334.2-1) is between 10% and 100% of the shell thickness t .

(5) The outer corner radius r_2 (Fig. NE-3334.2-1) is large enough to provide a smooth transition between the nozzles and the shell. In addition, for opening diameters greater than $1\frac{1}{2}$ times the shell thickness in cylindrical shells and 2:1 ellipsoidal heads and greater than three shell thicknesses in spherical shells, the value of r_2 shall not be less than one-half the thickness of the shell or nozzle wall, whichever is greater.

(6) The radius r_3 (Fig. NE-3334.2-1) is not less than the greater of the following:

(a) $0.002\theta d_o$ where d_o is the outside diameter of the nozzle and is as shown in Fig. NE-3334.2-1 and the angle θ is expressed in degrees;

(b) $2(\sin \theta)^3$ times offset for the configuration shown in Fig. NE-3334.2-1 sketches (a) and (b).

[98]

NE-3350 DESIGN OF WELDED CONNECTIONS

NE-3351 Welded Joint Categories

The term *Category* as used herein defines the location of a joint in a vessel but not the type of joint. The categories established by this paragraph are for specifying special requirements regarding joint type and degree of examination for certain welded pressure joints. Since these special requirements, which are based on service, material, and thickness, do not apply to every welded joint, only those joints to which special requirements apply are included in the categories. The

only when specifically stated. The joints included in each category are designated as joints of categories A, B, C, and D. Figure NE-3351-1 illustrates typical joint locations included in each category.

FIG. NE-3351-1 WELDED JOINT LOCATIONS TYPICAL OF CATEGORIES A, B, C, AND D

FIG. NE-3351-1 WELDED JOINT LOCATIONS TYPICAL OF CATEGORIES A, B, C, AND D

NE-3351.1 Category A.

Category A comprises longitudinal welded joints within the main shell or communicating chambers¹⁴ transitions in diameter or nozzles; welded joints within a sphere, within a formed or flat head, or within the side plates¹⁵ of a flat-sided vessel; circumferential welded joints connecting hemispherical heads to main shells, to transitions in diameters, to nozzles, or to communicating chambers.

NE-3351.2 Category B.

Category B comprises circumferential welded joints within the main shell or communicating chambers¹⁴ nozzles or transitions in diameter including joints between the transition and a cylinder at either the large or small end; or circumferential welded joints connecting formed heads other than hemispherical to main shells, transitions in diameter, nozzles, or communicating chambers.

¹⁴ Communicating chambers are defined as appurtenances to the vessel which intersect the shell or heads of a vessel and form an integral part of the pressure retaining closure.

¹⁵ Side plates of a flat-sided vessel are defined as any of the flat plates forming an integral part of the pressure retaining enclosure.

NE-3351.3 Category C.

Category C comprises welded joints connecting flanges, Van Stone laps, tube sheets, or flat heads to the main shell, formed heads, transitions in diameter, nozzles, or communicating chambers¹⁴ any welded joint connecting one side plate¹⁵ to another side plate of a flat-sided vessel.

NE-3351.4 Category D.

Category D comprises welded joints connecting communicating chambers¹⁴ or nozzles to main shells, spheres, transitions in diameter, heads, or flat-sided vessels, and those joints connecting nozzles to communicating chambers. For nozzles at the small end of a transition in diameter, see Category B.

NE-3352 Permissible Types of Welded Joints

The design of the vessel shall meet the requirements for each category of joint. Butt joints are full penetration joints between plates or other elements that lie approximately in the same plane. Category B angle joints between plates or other elements that have an offset angle α not exceeding 30 deg are considered as meeting the requirements for butt joints. Figure NE-3352-1 shows typical butt welds for each category joint.

NE-3352.1 Joints of Category A.

All welded joints of Category A as defined in NE-3351 shall meet the fabrication requirements of NE-4241 and shall be capable of being examined in accordance with NE-5210.

NE-3352.2 Joints of Category B.

All welded joints of Category B as defined in NE-3351 shall meet the fabrication requirements of NE-4242 and shall be capable of being examined in accordance with NE-5220.

FIG. NE-3352-1 TYPICAL BUTT JOINTS

FIG. NE-3352-1 TYPICAL BUTT JOINTS

NE-3352.3 Joints of Category C.

All welded joints of Category C as defined in NE-3351 shall meet the fabrication requirements of NE-4243 and shall be capable of being examined in accordance with NE-5230. The minimum dimensions of Fig. NE-4243-1 and Fig. NE-4243-2 shall be met where

t_c	= $0.7 t_n$ or $\frac{1}{4}$ in., whichever is less
t_w	= the lesser of t_n or $t/2$
t, t_n	= nominal thickness, in.

NE-3352.4 Joints of Category D.

All welded joints of Category D as defined in NE-3351 shall be in accordance with the requirements of NE-3359 and one of (a) through (f) below.

(a) *Butt Welded Nozzles.* Nozzles shall meet the fabrication requirements of NE-4244(a) and shall be capable of being examined in accordance with NE-5241. The minimum dimensions and geometrical requirements of Fig. NE-4244(a)-1 shall be met where:

t	= nominal thickness of part penetrated, in.
t_n	= nominal thickness of penetrating part, in.
r_1	= $\frac{1}{4}t$ or $\frac{3}{4}$ in. (19 mm), whichever is less
r_2	= $\frac{1}{4}$ in. (6 mm) minimum

(b) *Full Penetration Corner Welded Nozzles.* Nozzles shall meet the fabrication requirements of NE-4244(b) and shall be capable of being examined as required in NE-5242. Inserted-type nozzles having added reinforcement in the form of a separate reinforcing plate shall be attached by welds at the outer edge of the reinforcement plate and at the nozzle periphery. The weld at the outer edge of the reinforcement shall be a fillet weld with a minimum throat dimension of $\frac{1}{2}t_{\min}$. The minimum dimensions of Fig. NE-4244(b)-1 shall be met where:

t	= nominal thickness of part penetrated, in.
t_n	= nominal thickness of penetrating part, in.
t_c	= $0.7t_n$ or $\frac{1}{4}$ in. (6 mm), whichever is less

Page 104

r_1	= $\frac{1}{4}t$ or $\frac{3}{4}$ in. (19 mm), whichever is less
r_2	= $\frac{1}{4}$ in. (6 mm) minimum
t_e	= thickness of reinforcing element, in.
$t_{\min}$	= the smaller of $\frac{3}{4}$ in. (19 mm) or the thickness of the thinner of the parts joined

(c) *Use of Deposited Weld Metal for Openings and Nozzles*

(1) Nozzles shall meet the requirements of NE-4244(c) and shall be capable of being examined in accordance with NE-5243.

(2) When the deposited weld metal is used as reinforcement, the coefficients of thermal expansion of the base metal, the weld metal, and the nozzle shall not differ by more than 15% of the lowest coefficient involved.

(3) The minimum dimensions of Fig. NE-4244(c)-1 shall be met where:

t	= nominal thickness of part penetrated, in.
t_n	= nominal thickness of penetrating part, in.
t_c	= $0.7t_n$ or $1/4$ in. (6 mm), whichever is less
r_1	= $1/4t$ or $3/4$ in. (19 mm), whichever is less

(4) The corners of the end of each nozzle extending less than $\sqrt{dt_n}$ beyond the inner surface of the part penetrated shall be rounded to a radius of one-half the thickness t_n of the nozzle or $3/4$ in. (19 mm), whichever is smaller.

(d) Attachment of Nozzles Using Partial Penetration Welds

(1) Welded From Both Sides

(a) Partial penetration welds used to connect nozzles from both sides shall meet the requirements of NE-4244(d). Typical details are shown in Fig. NE-4244(d)-1. For inserted nozzles without reinforcing elements, two partial penetration welds may be used of any desired combination of fillet, single bevel, and single J-welds. Inserted-type nozzles having added reinforcement in the form of a separate reinforcing plate are not permitted with partial penetration welding.

(b) The minimum dimensions of Fig. NE-4244(d)-1 shall be met where:

$t_1 + t_2$	= $1/4t_{\min}$
t_1 or t_2	= not less than the smaller of $1/4$ in. (6 mm) or $0.7t_{\min}$
$t_{\min}$	= the smaller of $3/4$ in. (19 mm) or the thickness of the thinner of the parts joined
t	= nominal thickness of part penetrated, in.
t_n	= nominal thickness of penetrating part, in.
t_c	= $0.7t_n$ or $1/4$ in. (6 mm), whichever is less
c	= $1/2t_{\min}$
t_w	= $0.7t_n$

(2) Welded From One Side

(a) Partial penetration welds used to connect nozzles from one side are allowed only for attachments on which there are no piping reactions. They shall meet the fabrication requirements of NE-4244(d) and shall be capable of being examined in accordance with the requirements of NE-5242.

(b) The minimum dimensions of Fig. NE-4244(d)-2 shall be met where:

t	= nominal thickness of part penetrated, in.
t_n	= nominal thickness of penetrating part [or the lesser of t_{n1} or t_{n2} in Fig. NE-4244(d)-2], in.
t_c	= $0.7t_n$ or $1/4$ in. (6 mm), whichever is less
r_1	= $1/4t_n$ or $3/4$ in. (19 mm), whichever is less
d	= outside diameter of nozzle [or of the inner cylinder as shown in Fig. NE-4244(d)-2], in.
c	= diametral clearance between nozzle and vessel penetration, in.

= 0.010 in. (0.25 mm) for $d \leq 1$ in. (25 mm).
 = 0.020 in. (0.51 mm) for $1 < d \leq 4$ in. (102 mm) and
 = 0.030 in. (0.76 mm) for $d > 4$ in. (102 mm) maximum,
 except that the above limits on maximum clearance need not
 be met for the full length of the opening, provided there is a
 region at the weld preparation and a region near the end of the
 opening opposite the weld which does meet the above limits
 on maximum clearance and the latter region is extensive
 enough (not necessarily continuous) to provide a positive stop
 for nozzle deflection

r_2	= $\frac{1}{16}$ in. (1.6 mm) minimum
r_3	= r_2 or equivalent chamfer, minimum
λ	= $\frac{1}{16}$ in. (1.6 mm) minimum
λ	= t_n maximum
r_4	= $\frac{1}{2}t_n$ or $\frac{3}{4}$ in. (19 mm), whichever is smaller

(3) The corners to the end of each nozzle extending less than $\sqrt{d}t_n$ beyond the inner surface of the part penetrated shall be rounded to a radius of one-half of the thickness t_n of the penetrating part or $\frac{3}{4}$ in. (19 mm), whichever is smaller.

(4) Weld groove design for partial penetration joints attaching nozzles may require special consideration to achieve the $1.25t_n$ minimum depth of weld and adequate access for welding examination. The welds shown in the sketches of Fig. NE-4244(d)-2 and Fig. NE-4244(d)-3 may be on either the inside or the outside of the shell. Weld preparation may be J-groove as shown in the figures or straight bevel.

(e) *Attachment of Fittings with Internal Threads.*¹⁶ The attachment of internally threaded fittings shall meet the requirements of (1) through (3) below.

¹⁶ This paragraph is written for fittings with internal threads, but is applicable to externally threaded or butt welded fittings.

(1) Except as provided for in (2) and (3) below, the provisions of NE-4244(e) shall be met. The minimum weld dimensions shall be as shown in Fig. NE-4244(e)-1 where:

$t_{\min}$	= lesser of $\frac{3}{4}$ in. (19 mm) or the thickness of the parts joined
t_c	= $\frac{1}{4}$ in. (6 mm), minimum

Details in sketches (a) and (b):

$$t_1 + t_2 = 1\frac{1}{4}t_{\min}$$

Detail in sketch (c):

t_w	= thickness of Sch. 160 pipe (ANSI-B36.10), in.
$t_1 + t_2$	= not less than smaller of $\frac{1}{4}$ in. (6 mm) or $0.7t_{\min}$

Detail in sketch (d):

c	= $\frac{1}{2}t_{\min}$
t_w	= $0.7t_{\min}$

(2) Fittings shown in Fig. NE-4244(e)-1 sketches (a-2), (b-2), (c-2), and (d) not exceeding NPS 2 may be attached by

welds that are exempt from size requirements other than those specified in NE-3359.

(3)(a) When internally threaded fittings and bolting pads not exceeding NPS 3 (DN 80) are attached to vessels having a wall thickness not greater than $\frac{3}{8}$ in. (10 mm) by a fillet weld deposited from the outside only, the welds shall comply with the dimensions shown in Fig. NE-4244(e)-2. These openings do not require reinforcement other than that inherent in the construction as permitted in NE-3332.1.

(b) If the opening exceeds NPS 5 (DN 125), it shall be reinforced in accordance with NE-3332 with the nozzle or other connections attached, using a suitable detail in Fig. NE-4244(e)-1.

(f) *Attachment of Tubed Connections.* Tubes recessed into thick walled vessels or headers, welded from only one side, shall have a welding groove in the vessel wall not deeper than t_n on the longitudinal axis of the opening. A recess $\frac{1}{16}$ in. (1.6 mm) deep shall be provided at the bottom of the groove in which to center the nozzle. The dimension t_w of the attachment weld shall not be less than t_n nor less than $\frac{1}{4}$ in. (6 mm). The minimum dimension for t_c shall be $\frac{1}{4}$ in. (6 mm) [Fig. NE-4244(f)-1 sketches (a) and (b)].

NE-3355 Welding Grooves

The dimensions and shape of the edges to be joined shall be such as to permit complete fusion and penetration, except as otherwise permitted in NE-3352.4.

NE-3356 Fillet Welds

(a) Corner or T-joints for Category C welds may be made with fillet welds, provided the attachment is properly supported independently of such welds. Closures which meet the requirements of NE-3367 may be attached by fillet welds.

(b) The allowable load on fillet welds shall equal the product of the weld area based on minimum leg dimension, the allowable stress value in tension of the material being welded, and the factor 0.55.

(c) Except where specific details are permitted in other paragraphs, welded joints subject to bending stresses shall have fillet welds added where necessary to reduce stress concentration. Corner joints, with fillet welds only, shall not be used unless the plates forming the corner are properly supported independently of such welds.

NE-3358 Design Requirements for Head Attachments

NE-3358.1 Skirt Length of Formed Heads

(a) Ellipsoidal and other types of formed heads, concave or convex to the pressure, shall have a skirt length not less than that shown in Fig. NE-3358.1(a)-1. Heads that are fitted inside or over a shell shall have a driving fit before welding.

(b) A tapered transition, having a length not less than three times the offset between the adjacent surfaces of abutting sections as shown in Fig. NE-3358.1(a)-1, shall be provided at joints between formed heads and shells that differ in thickness by more than one-fourth the thickness of the thinner section or by more than $\frac{1}{8}$ in. (3.2 mm), whichever is less. When a taper is required on any formed head thicker than the shell and intended for butt welded attachment [Fig. NE-3358.1(a)-1], the skirt shall be long enough so that the required length of taper does not extend beyond the tangent line.

NE-3358.2 Unstayed Flat Heads Welded to Shells.

The requirements for the attachment of unstayed flat heads welded to shells are given in NE-3325, NE-3358.3, and NE-3358.4.

NE-3358.3 Head Attachments Using Corner Joints.

When shells, heads, or other pressure parts are welded to a forged or rolled plate to form a corner joint, as in Fig. NE-4243-1 and Fig. NE-4243-2, the joint shall meet the requirements of (a) through (e) below.

(a) On the cross section through the welded joint, the line of fusion between the weld metal and the forged or rolled plate being attached shall be projected on planes both parallel to and perpendicular to the

Page 106

surface of the plate being attached, in order to determine the dimensions a and b , respectively.

GENERAL NOTES [sketches (a) and (b)]:

- (a) Length of required taper l may include the width of the weld.
- (b) In all cases, the projected length of taper l shall be not less than $3y$.
- (c) The shell plate center line may be on either side of the head plate center line.

GENERAL NOTES [sketches (c) and (d)]:

- (a) In all cases l shall be not less than 3 times y when t_h exceeds $1.25t_s$; minimum length of skirt is $3t_h$, but need not exceed 1-1/2 in. except when necessary to provide required length of taper.
- (b) When t_h is equal to or less than $1.25t_s$, length of skirt shall be sufficient for any required taper.
- (c) Length of required taper l may include the width of the weld.
- (d) The shell plate center line may be on either side of the head plate center line.

FIG. NE-3358.1(a)-1 HEADS ATTACHED TO SHELLS

FIG. NE-3358.1(a)-1 HEADS ATTACHED TO SHELLS

(b) For flange rings of bolted flanged connections, and for flat heads with a projection having holes for a bolted connection, the sum of a and b shall not be less than three times the nominal wall thickness of the abutting pressure part.

(c) For other components, the sum of a and b shall not be less than two times the nominal wall thickness of the abutting pressure part. Examples of such components are flat heads without a projection having holes for a bolted connection and the side plates of a rectangular vessel.

(d) Other dimensions at the joint shall be in accordance with details as shown in Fig. NE-4243-1 and Fig. NE-4243-2 where:

In Fig. NE-4243-1:

e not less than t_f

NE-3359 Design Requirements for Nozzle Attachment Welds

In addition to the requirements of NE-3352.4, the minimum design requirements for nozzle attachment welds shall be as stipulated in (a) and (b) below.

$17t_d$ is defined in XI-3130.

(a) *Required Weld Strength.* Sufficient welding shall be provided on either side of the line through the center of the opening parallel to the longitudinal axis

Page 108

of the shell to develop the strength of the reinforcing parts as prescribed in NE-3336, through shear or tension in the weld, whichever is applicable. The strength of groove welds shall be based on the area subjected to shear or to tension. The strength of fillet welds shall be based on the area subjected to shear computed on the minimum leg dimension. The inside diameter of a fillet weld shall be used in figuring its length. Calculations are not required for full penetration welds.

GENERAL NOTE: Length of taper may include the width of the weld.

FIG. NE-3361-1 CATEGORY A AND B JOINTS BETWEEN SECTIONS OF UNEQUAL THICKNESS

FIG. NE-3361-1 CATEGORY A AND B JOINTS BETWEEN SECTIONS OF UNEQUAL THICKNESS

(b) *Allowable Stress Values for Welds.* The allowable stress values for groove and fillet welds and for shear in nozzles, in

percentage of stress values for the vessel material, are as follows:

Nozzle wall shear	70%
Groove weld tension	74%
Groove weld shear	60%
Fillet weld shear	49%

NE-3360 SPECIAL VESSEL REQUIREMENTS

NE-3361 Tapered Transitions

A tapered transition having a length not less than three times the offset between the adjacent surfaces of abutting sections (Fig. NE-3361-1) shall be provided at joints between sections that differ in thickness by more than one-fourth the thickness of the thinner section or by more than $\frac{1}{8}$ in. (3.2 mm), whichever is less. The transition may be formed by any process that will provide a uniform taper. The weld may be partly or entirely in the tapered section or adjacent to it.

NE-3362 Bolted Flange and Studded Connections

(a) It is recommended that the dimensional requirements of bolted flange connections to external piping conform to ANSI B16.5, Steel Pipe Flanges and Flanged Fittings, ANSI B16.24, Brass or Bronze Flanges and Flanged Fittings, 150 and 300 lb, MSS SP-42, 150 lb Corrosion Resistant Cast Flanged Valves, or to API 605, Large Diameter Carbon Steel Flanges. Such flanges and flanged fittings may be used for the pressure-temperature ratings given in the appropriate standard. Flanges and flanged fittings in accordance with other standards are acceptable, provided they have been designed in accordance with the rules of Appendix XI for the vessel Design Loadings and are used within the pressure-temperature ratings so determined.

(b) Where tapped holes are provided for studs, the threads shall be full and clean, and shall engage the stud for a length not less than the larger of d_s or:

$$0.75d_s \times \frac{\text{Maximum allowable stress value of stud material at Design Temperature}}{\text{Maximum allowable stress value of tapped material at Design Temperature}}$$

in which d_s is the diameter of the stud. The thread engagement need not exceed $1\frac{1}{2}d_s$.

NE-3363 Access Openings

Access openings, where provided, shall consist of handhole or manhole openings having removable covers. These may be located on either the inside or outside of the shell or head openings and may be attached by studs or bolts in

combination with gaskets or welded membrane seals or strength welds. Plugs using pipe threads are not permitted.

NE-3364 Attachments

Attachments used to transmit support loads shall meet the requirements of NE-3135.

NE-3365 Supports

All vessels shall be so supported and the supporting members shall be so arranged and attached to the vessel wall as to provide for the maximum imposed loadings. The stresses produced in the vessel by such loadings and by steady state and transient thermal conditions shall be limited to the stress limits of this Subsection. For design of supports, see Subsection NF.

NE-3366 Bellows Expansion Joints

NE-3366.1 General Requirements.¹⁸

Expansion or bellows-type joints may be used to provide flexibility for containment systems. Expansion joints in piping portions of the containment system shall meet the requirements for Class 2 piping. The expansion joints which are constructed as a part or appurtenance of the vessel shall conform to this Subsection and shall conform with the requirements of (a) through (h) below.

(a) Bellows may be used to absorb axial movement, lateral deflection, angular rotation, or any combination of these movements. They are not normally designed for absorbing torsion. The layout, anchorage, guiding, and support shall be such as to avoid the imposition of motions or forces on the bellows other than those for which they have been designed.

¹⁸ For general information, see standards of the Expansion Joint Manufacturers Association, Inc., 25 N. Broadway, Tarrytown, NY 10591.

(b) In all systems containing bellows, the hydrostatic end force caused either by pressure or the bellows spring force or both must be resisted by rigid anchors, cross connections of the expansion joint ends, or other means.

(c) The expansion joint shall be installed in such locations as to be accessible for scheduled inspection, where applicable.

(d) The joints shall be provided with bars or other suitable members for maintaining the proper face-to-face dimension during shipment and installation. Bellows shall not be extended or compressed to make up deficiencies in length or offset to accommodate connecting parts which are not properly aligned unless such movements have been specified by the system designer or can be justified by the expansion joint manufacturer.

(e) The expansion joints shall be marked to show the direction of flow, if applicable, and shall be installed in accordance with this marking.

(f) Internal sleeves shall be provided for expansion joints over 6 in. (152 mm) in diameter when flow velocities exceed the following values:

(1) air, steam, and other gases - 25 ft/sec (7.6 m/s)

(2) water and other liquids - 10 ft/sec (3.0 m/s)

(g) Pressure retaining materials shall conform to the requirements of NE-2000. Convolutions or toroids of a bellows expansion joint shall be fabricated from material in the annealed condition.

(h) All welded joints in the expansion joint shall comply with the requirements of NE-4400 and NE-4800.

NE-3366.2 Design Requirements.

Bellows may be of the unreinforced or reinforced convoluted type or the toroidal type. The design shall conform to NE-3000 except as stipulated in (a) through (j) below.

(a) The circumferential membrane stresses in both the bellows and the reinforcing member, due to pressure, shall not exceed 1.1 times the allowable stress value given in Section II, Part D, Subpart 1, Tables 1A and 1B for the material at

the design temperature.

(b) The sum of the bellows meridional membrane and bending stresses due to internal pressure shall not exceed a value which results in a permanent decrease in the measured space between adjacent convolutions of 7% after the pressure test required by NE-6230.

(c) The ratio of the internal pressure at which the bellows will become unstable (squirm) to the equivalent cold service pressure shall exceed 2.25. By definition, squirm shall be considered to have occurred if under internal pressure an initially symmetrical bellows deforms, resulting in a lack of parallelism or uneven spacing of adjacent convolutions at any point on the circumference. Unless otherwise specified, this deformation shall be construed as unacceptable squirm when

Page 110

the ratio of the maximum convolution pitch under internal pressure exceeds 1.15 for unreinforced and 1.20 for reinforced bellows. In the case of universal expansion joints, which consist of two bellows joined by a cylindrical section, compliance with these criteria shall be satisfied by the entire assembly. No external restraints on the bellows shall be employed during squirm testing other than those which will exist after installation.

(1) For single joints used in axial or lateral motion, the squirm test may be performed with the bellows fixed in the straight position at the maximum length expected in service; for rotation and universal joints, the bellows shall be held at the maximum design rotation angle or offset movement. In the case of single joints subjected to rotation movement, or of universal joints subjected to lateral offset movement, an instability condition as previously defined may or may not appear. Instead, movement of the convolutions may occur due to the superposition of the lateral internal pressure component on the applied rotation. In such cases, that portion of the bellows deformation due to the design rotation angle or offset movement shall not be included in the deformation used to define squirm.

(2) In the case of squirm tests, the equivalent cold service pressure is defined as the Design Pressure multiplied by the ratio E_c/E_h , where E_c and E_h are defined as the modulus of elasticity of the bellows material at room temperature and normal service temperature, respectively.

(d) The combination of meridional membrane and bending stresses S in the bellows due to internal pressure and deflection, multiplied by a stress factor K_s ,¹⁹ shall not exceed the value defined by the following equation:

$$K_s \times S = S_f$$

where

K_s	= $K_{sc} \times K_{ss}$, but never less than 1.25
K_{sc}	= factor for differences in design fatigue curves at temperatures greater than 100°F, and is equal to:

$$\frac{2S_c}{S_c + S_h}$$

K_{ss}	= factor for the statistical variation in test results = $1.470 - 0.044$ times the number of replicate tests
----------	--

S	= total combined meridional membrane and bending stress, psi, due to pressure and deflection (the calculation of the individual stress components and their combination shall be determined by the same method as used for determining S_f); in the case of single joints subjected to rotation movement and universal joints subjected to lateral offset movement, the increase in deflection stress caused by the lateral internal pressure component shall be included in determining the combined stress, psi
S_f	= total combined stress to failure at design cyclic life, psi, (number of cycles to failure) obtained from plots of stress versus cyclic life based on data from fatigue tests of a series of bellows at a given temperature (usually room temperature) evaluated by a best-fit continuous curve or series of curves; the S_f plot shall be parallel to the best-fit curve and shall lie below all of the data points
S_c	= basic material allowable stress value at room temperature from Section II, Part D, Subpart 1, Tables 1A and 1B, psi, times 1.1
S_h	= basic material allowable stress value at normal service temperature from Section II, Part D, Subpart 1, Tables 1A and 1B, psi, times 1.1

(e) Compliance with (a), (b), (c), and (d) above shall be demonstrated by any one of the procedures of (1) through (3) below.

(1) Calculation of the individual stresses, whose combination and relation to fatigue life may be performed by any analytical method based on elastic shell theory. The resulting equations shall be substantiated by correlation with actual tests of a consistent series of bellows of the same basic design (unreinforced, reinforced, and toroidal bellows are considered as separate designs) by each bellows manufacturer in order to demonstrate predictability of rupture pressure, meridional yielding, squirm, and cyclic life. A minimum of five burst tests on bellows of varying sizes, with not less than three convolutions, shall be conducted to verify that the analytical method will adequately satisfy (a) and (b) above. No specimen shall rupture at less than four times its equivalent cold pressure rating. A minimum of ten squirm tests on bellows of varying diameters and number of convolutions shall be conducted to verify that the analytical method will adequately satisfy (c) above. Since column instability is most likely to occur in bellows less than 20 in. in diameter when the convoluted bellows length is greater than its diameter, the test specimens shall reflect these considerations. In the case of universal expansion joints, two additional tests shall be conducted to verify that the analytical method will adequately satisfy (c) above. The cyclic life plot (versus the combined stress) used

Page 111

in evaluating NE-3365.1(d) shall be obtained from the results of at least 25 fatigue tests on bellows of varying diameters, thicknesses, and convolution profiles. These curves may be used for diameter and convolution profiles other than those tested, provided that a variation in these dimensions has been included in the correlation with test data. Each group of five such tests on varying bellows may be considered the equivalent of one replicate test in determining K_s .

(2) Individual expansion joint designs may be shown to comply by the testing of duplicate bellows. At least two test specimens are required, one to demonstrate pressure capacity in accordance with (a), (b), and (c) above, and the second to demonstrate fatigue life in accordance with (d) above. In the case of rupture and fatigue tests, the specimens need not possess a duplicate number of convolutions provided that the number of convolutions is not less than three and the diameter, thickness, depth, and pitch of the specimen is identical to the part to be furnished. Squirm test specimens shall possess the total number of convolutions. The pressure test required by NE-6230 shall satisfy the instability test

requirements for bellows larger than 50 in. in diameter.

(a) The test of (e)(1) or (e)(2) above may be conducted at room temperature provided that cold service pressure is defined as the Design Pressure multiplied by the ratio of S_c/S_h for rupture specimens and E_c/E_h for squirm specimens.

(b) The fatigue life of the test specimen shall exceed $K_s^{4.3}$ times the number of design cycles specified for the most significant cyclic movements. This test shall include the effect of internal pressure. If lateral and rotation movements are specified, these may be converted to equivalent axial motion for cyclic testing; the convolution deflection produced by the lateral component of the internal pressure force during the squirm test (for single rotation joints and universal joints) shall be added to the mechanical deflections in determining fatigue life. Where accelerated fatigue testing is employed, the deflection and number of cycles required shall be in accordance with Appendix II. Cumulative fatigue requirements can be satisfied in accordance with NE-3365.1(g) without additional testing by assuming that the slope of the fatigue curve is 4.3 (on a log-log plot) and that the curve passes through the test point.

(3) An individual design may be shown to comply by a design analysis in accordance with NE-3200. The stresses at every point in the bellows shall be determined by either elastic shell theory or by a plastic analysis, where applicable. Where an elastic analysis is employed, stress intensity Tables 2A, 2B, and 4 in Section II, Part D, Subpart 1 and fatigue curves of Appendix I may be used to evaluate the design. The stability requirements of (c) above may be demonstrated by either (3)(a) or (3)(b) below:

(a) elastic stability calculations, provided that the ratio of the internal pressure at which the bellows is predicted to become unstable to the equivalent cold operating pressure exceeds 10; or

(b) the pressure test of NE-6230, provided that the test is conducted at 2.25 times the equivalent cold design pressure, and single rotation and universal joints are held at their design rotation angle or offset movement during the test and the requirements of NE-3365.1(b) are not exceeded by such a test. (The pressure test required by NE-6230 shall satisfy the instability test requirements for bellows larger than 50 in. in diameter.)

(f) The bellows manufacturer's design report shall state which of the above procedures was utilized to verify the design.

(g) If there are two or more types of stress cycles which produce significant stresses, their cumulative effect shall be evaluated as stipulated in NE-3221.5(e)(5).

(h) Where necessary to carry the pressure, the cylindrical ends of the bellows may be reinforced by suitable collars; the design method used to assure that the stresses generated will not cause premature failure of the bellows material or weldment shall include the attachment weld between the bellows and end connections.

(i) If reinforcing rings are used, they shall have the same radius as the root of the convolution.

(j) The Design Specifications shall state the maximum allowable force that can be imposed on the connecting parts or shall request the bellows manufacturer to determine the force necessary to deflect the bellows a given distance, preferably the maximum movement to be absorbed.

NE-3367 Closures on Small Penetrations

Closures on penetrations of 2 in. pipe size (DN 50) or less may be made by the use of closure fittings such as blind flanges, welded plugs, or caps manufactured in accordance with standards listed in Table NE-3132-1.

NE-3700 ELECTRICAL AND MECHANICAL PENETRATION ASSEMBLIES

NE-3720 DESIGN RULES

(a) The design of the pressure retaining portion of the electrical and mechanical penetration assemblies shall be the same as for vessels (NE-3300).

Page 112

(b) For closing seams in electrical and mechanical penetrations meeting the requirements of NE-4730(c), the closure head shall meet the requirements of NE-3325 using a factor $C=0.30$. The fillet weld shall be designed using an allowable stress of

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NE-4000

ARTICLE NE-4000 FABRICATION AND INSTALLATION

Page 113

NE-4100 GENERAL REQUIREMENTS

NE-4110 INTRODUCTION

Containment vessels, penetration assemblies, and appurtenances shall be fabricated and installed in accordance with the requirements of this Article, and shall be manufactured from materials which meet the requirements of NE-2000.

NE-4120 CERTIFICATION OF MATERIAL AND FABRICATION BY COMPONENT CERTIFICATE HOLDER

NE-4121 Means of Certification

The Certificate Holder for an item for a containment vessel shall certify by application of the appropriate Code Symbol and completion of the appropriate Data Report in accordance with NCA-8000 that the materials used comply with the requirements of NE-2000, and that the fabrication complies with the requirements this Article.

NE-4121.1 Certification of Treatments, Tests, and Examinations.

If the Certificate Holder or Subcontractor performs treatments, tests, repairs, or examinations required by other Articles of this Subsection, the Certificate Holder shall certify that this requirement has been fulfilled (NCA-3862). Reports of all required treatments and the results of all required tests, repairs, and examinations performed shall be available to the Inspector.

NE-4121.2 Repetition of Tensile or Impact Tests.

If during the fabrication of the vessel the material is subjected to heat treatment that has not been covered by treatment of the test coupons (NE-2200) and that may reduce either the tensile or impact properties below the required values, the tensile and impact tests shall be repeated by the Certificate Holder on test specimens taken from test coupons which have been taken and treated in accordance with the requirements of NE-2000.

NE-4122 Material Identification

(a) Material for pressure retaining parts shall carry identification markings which will remain distinguishable until the component is assembled or installed. If the original identification markings are cut off or the material is divided, the marks shall be either transferred to the parts cut or a coded marking shall be used to assure identification of each piece of material during subsequent fabrication or installation. In either case, an as-built sketch or a tabulation of materials shall be made identifying each piece of material with the Certified Material Test Report, where applicable, and the coded marking. For studs, bolts, and nuts, it is permissible to identify the Certified Material Test Reports for material in each component in lieu of identifying each piece of material with the Certified Material Test Report and the coded marking. Material supplied with a Certificate of Compliance and welding materials shall be identified and controlled so that they can be traced to the vessel, or else a control procedure shall be employed which ensures that the specified material is used.

(b) Material from which the identification marking is lost shall be treated as nonconforming material until appropriate tests or other verifications are made and documented to assure material identification. Testing is required unless positive identification can be made by other documented evidence. The material may then be remarked, upon establishing positive identification.

NE-4122.1 Marking Material.

Material shall be marked in accordance with NCA-3866.6.

NE-4123 Examinations

Visual examination activities that are not referenced for examination by other specific Code paragraphs, and are performed solely to verify compliance with

Page 118

requirements of NE-4000, may be performed by the persons who perform or supervise the work. These visual examinations are not required to be performed by personnel and procedures qualified to NE-5500 and NE-5100, respectively, unless so specified.

NE-4125 Testing of Welding Material

All welding material shall meet the requirements of NE-2400.

NE-4130 REPAIR OF MATERIAL

NE-4131 Elimination and Repair of Defects

Material originally accepted on delivery in which defects exceeding the limits of NE-2500 are known or discovered during the process of fabrication or installation is unacceptable. The material may be used provided the condition is corrected in accordance with the requirements of NE-2500 for the applicable product form, except:

- (a) the limitation on the depth of the weld repair does not apply;
- (b) the time of examination of the weld repairs to weld edge preparations shall be in accordance with NE-5130; and
- (c) radiographic examination is not required for weld repairs to seal membrane material when the material thickness is $\frac{1}{4}$ in. (6 mm) or less.

NE-4200 FORMING, FITTING, AND ALIGNING

NE-4210 CUTTING, FORMING, AND BENDING

NE-4211 Cutting

Plates, edges of heads, and other parts may be cut to shape and size by mechanical means such as machining, shearing, grinding, or by oxygen or arc cutting. After oxygen cutting, the edges to be welded shall be uniform and smooth and shall be free of all loose scale and slag accumulations before welding.

NE-4211.1 Preheating Before Thermal Cutting.

When thermal cutting is performed to prepare weld joints or edges, to remove attachments or defective material, or for any other purpose, consideration shall be given to preheating the material using preheat schedules such as suggested in Appendix D.

NE-4212 Forming and Bending Processes

Any process may be used to hot or cold form or bend pressure retaining material, including weld metal, provided the required dimensions are attained (see NE-4214 and NE-4220), and provided the impact properties of the material, when required, are not reduced below the minimum specified values or they are effectively restored by heat treatment following the forming operation. *Hot forming* is defined as forming with the material temperature higher than 100°F (56°C) below the lower transformation temperature of the material. When required, the process shall be qualified for impact properties as outlined in NE-4213.

NE-4212.1 Required Postweld Heat Treatment.

Vessel shell sections and heads of P-No.1 material fabricated by cold forming shall be postweld heat treated when the resulting maximum extreme fiber elongation is more than 5%.

NE-4213 Qualification of Forming Processes for Impact Property Requirements

A procedure qualification test shall be conducted using specimens taken from material of the same specification, grade or class, heat treatment, and with similar impact properties as required for the material in the vessel. These specimens shall be subjected to the equivalent forming or bending process and heat treatment as the material in the vessel. Applicable tests shall be conducted to determine that the required impact properties of NE-2300 are met after straining.

NE-4213.1 Exemptions.

Procedure qualification tests are not required for material listed in (a) through (f) below:

- (a) hot formed material, such as forgings, in which the hot forming is completed by the Material Organization prior to removal of the impact test specimens;
- (b) hot formed material represented by test coupons required in either NE-2211 or NE-4121.2 which have been subjected to heat treatment representing the hot forming procedure and the heat treatments to be applied to the parts;
- (c) material which does not require impact tests in accordance with NE-2300;
- (d) material which has final strain less than 0.5%;
- (e) material where the final strain is less than that of a previously qualified procedure for that material;
- (f) material from which the impact testing required by NE-2300 is performed on each heat and lot, as applicable, after forming.

Page 119

NE-4213.2 Procedure Qualification Test.

The procedure qualification test shall be performed in the manner stipulated in (a) through (f) below.

- (a) The tests shall be performed on three different heats of material both before and after straining to establish the effects of the forming and subsequent heat treatment operations.
- (b) Specimens shall be taken in accordance with the requirements of NE-2000 and shall be taken from the tension side of the strained material.
- (c) The percent strain shall be established by the following formulas.

For cylinders:

$$\% \text{ strain} = \frac{50t}{R_f} \left(1 - \frac{R_f}{R_o} \right)$$

For spherical or dished surfaces:

$$\% \text{ strain} = \frac{75t}{R_f} \left(1 - \frac{R_f}{R_o} \right)$$

For pipe:

$$\% \text{ strain} = \frac{100r}{R}$$

where

t	= nominal thickness, in.
R_f	= final radius to center line of shell, in.
R_o	= original radius (equal to infinity for a flat part), in.
R	= nominal bending radius to the center line of the pipe, in.
r	= nominal radius of the pipe, in.

(d) The procedure qualification shall simulate the maximum percent surface strain, employing a bending process similar to that used in the fabrication of the material or by direct tension on the specimen.

(e) Sufficient C_v test specimens shall be taken from each of the three heats of material to establish a transition curve showing both the upper and lower shelves. On each of the three heats, tests consisting of three impact specimens shall be conducted at a minimum of five different temperatures distributed throughout the transition region. The upper and lower shelves may be established by the use of one test specimen for each shelf. Depending on the product form, it may be necessary to plot the transition curves using both lateral expansion and energy level data (NE-2300). In addition, drop weight tests shall be made when required by NE-2300.

(f) Using the results of the impact test data from each of three heats taken both before and after straining, determine either:

(1) the maximum change in NDT temperature along with:

(a) the maximum change of lateral expansion and energy at the temperature under consideration; or

(b) the maximum change of temperature at the lateral expansion and energy levels under consideration; or

(2) when lateral expansion is the acceptance criterion (NE-2300), either the maximum change in temperature or the maximum change in lateral expansion.

NE-4213.3 Acceptance Criteria for Formed Material.

To be acceptable, the formed material used in the vessel shall have impact properties before forming sufficient to compensate for the maximum loss of impact properties due to the qualified forming procedure used.

NE-4213.4 Requalification.

A new procedure qualification test is required when any of the following changes are made:

(a) the actual postweld heat treatment time at temperature is greater than previously qualified, considering NE-2211:

(1) if the material is not postweld heat treated, the procedure shall be qualified without postweld heat treatment;

(b) the maximum calculated strain of the material exceeds the previously qualified strain by more than 0.5%;

(c) where preheat over 250°F (121°C) is used in the forming or bending operation but not followed by a subsequent postweld heat treatment.

NE-4214 Minimum Thickness of Fabricated Material

If any fabrication operation reduces the thickness below the minimum required to satisfy the rules of NE-3000, the material may be repaired in accordance with NE-4130.

NE-4220 FORMING TOLERANCES

NE-4221 Tolerance for Vessel Shells

Cylindrical, conical, or spherical shells of a completed vessel, except for formed heads covered by NE-4222, shall meet the requirements of the following subparagraphs at all cross sections. If the plates are to be rolled, the adjoining edges of longitudinal joints of cylindrical vessels shall first be shaped to the proper

Page 120

curvature by preliminary rolling or forming in order to avoid having objectional flat spots along the completed joints.

**FIG. NE-4221.1-1 MAXIMUM DIFFERENCE
IN CROSS-SECTIONAL DIAMETERS**

FIG. NE-4221.1-1 MAXIMUM DIFFERENCE IN CROSS-SECTIONAL DIAMETERS

NE-4221.1 Maximum Difference in Cross-Sectional Diameters.

The difference between the maximum and minimum inside diameters at any cross section shall not exceed 1% of the nominal diameter at the cross section under consideration. The diameters may be measured on the inside or outside of the vessel. If measured on the outside, the diameters shall be corrected for the plate thickness at the cross section under consideration (Fig. NE-4221.1-1). When the cross section passes through an opening, the permissible difference in inside diameters given above may be increased by 2% of the inside diameter of the opening.

NE-4221.2 Maximum Deviation From True Theoretical Form for External Pressure.

Vessels designed for external pressure shall meet the following tolerances.

(a) The maximum plus-or-minus deviation from the true circular form of cylinders or the theoretical form of other shapes, measured radially on the outside or inside of the component, shall not exceed the maximum permissible deviation obtained from Fig. NE-4221.2-1. Measurements shall be made from a segmental circular template having the design inside or outside radius (depending on where the measurements are taken) and a chord length equal to twice the arc length obtained from Fig. NE-4221.2-2. For Fig. NE-4221.2-1, the maximum permissible deviation e need not be less than $0.3t$. For Fig. NE-4221.2-2, the arc length need not be greater than $0.30D_o$. Measurements shall not be taken on welds or other raised parts.

(b) The value of t in inches at any cross section is the nominal plate thickness less corrosion allowance for sections of constant thickness and the nominal thickness of the thinnest plate less corrosion allowance for sections having plates of more than one thickness.

(c) The value of L in Fig. NE-4221.2-1 and Fig. NE-4221.2-2 is determined as follows.

(1) For cylinders, L is as given in NE-3133.2.

(2) For cones, L is the axial length of the conical section if no stiffener rings are used or, if stiffener rings are used, the axial length from the head bend line at the large end of the cone to the first stiffener ring, with D_o taken as the outside diameter in inches of the cylinder at the large end of the cone.

(3) For spheres, L is one-half of the outside diameter D_o , in.

NE-4221.3 Deviations From Tolerances.

Deviations from the tolerance requirements stipulated in NE-4221.1 and NE-4221.2 are permitted, provided the drawings are modified and reconciled with the Design Report and provided the modifications are certified by a Registered Professional Engineer in an addendum to the Design Report.

NE-4221.4 Tolerance Deviations for Vessel Parts Fabricated From Pipe.

Vessel parts subjected to either internal or external pressure and fabricated from pipe, meeting all other requirements of this Subsection, may have variations of diameter and deviations from circularity permitted by the specification for such pipe.

NE-4221.5 Localized Thin Areas.

Localized thin areas are permitted if the adjacent areas surrounding each has sufficient thickness to provide the necessary reinforcement according to the rules for reinforcement in NE-3330.

NE-4222 Tolerances for Formed Vessel Heads

The tolerance for formed vessel heads shall be as set forth in the following subparagraphs.

NE-4222.1 Maximum Difference in Cross-Sectional Diameters.

The skirt or cylindrical end of a formed head shall be circular to the extent that the difference in inches between the maximum and minimum diameters does not exceed the lesser of $(D + 50)/200$ or $(D + 12)/100$, where D is the nominal inside diameter in inches and shall match the cylindrical edge of the adjoining part within the alignment tolerance

specified in NE-4232.

NE-4222.2 Deviation From Specified Shape

(a) The inner surface of a torispherical or ellipsoidal head shall not deviate outside the specified shape by more than $1\frac{1}{4}\%$ of D , or inside the specified shape by more than $\frac{5}{8}\%$ of D , where D is the nominal inside diameter of the vessel. Such deviations shall be measured perpendicular to the specified shape and shall

Page 121

not be abrupt. The knuckle radius shall not be less than specified. For 2:1 ellipsoidal heads, the knuckle radius may be considered to be 17% of the diameter of the vessel.

TABLE NE-4232-1
MAXIMUM ALLOWABLE OFFSET IN
FINAL WELDED JOINTS

Section Thickness, in.	Longitudinal	Circumferential
Up to $\frac{1}{2}$, incl.	$\frac{1}{4} t$	$\frac{1}{4} t$
Over $\frac{1}{2}$ to $\frac{3}{4}$, incl.	$\frac{1}{8}$ in.	$\frac{1}{4} t$
Over $\frac{3}{4}$ to $1\frac{1}{2}$, incl.	$\frac{1}{8}$ in.	$\frac{3}{16}$ in.
Over $1\frac{1}{2}$ to 2, incl.	$\frac{1}{8}$ in.	$\frac{1}{8} t$
Over 2	Lesser of $\frac{1}{16} t$ and $\frac{3}{8}$ in.	Lesser of $\frac{1}{8} t$ and $\frac{3}{4}$ in.

TABLE NE-4232-1 MAXIMUM ALLOWABLE OFFSET IN FINAL WELDED JOINTS

(b) Hemispherical heads and any spherical portion of a formed head shall meet the local tolerances for spheres as given in NE-4221.2, using L as the outside spherical radius in inches and D_o as two times L .

(c) Deviation measurements shall be taken on the surface of the base material and not on welds.

NE-4230 FITTING AND ALIGNING

NE-4231 Fitting and Aligning Methods

Parts that are to be joined by welding may be fitted, aligned, and retained in position during the welding operation by the use of bars, jacks, clamps, tack welds, or temporary attachments.

NE-4231.1 Tack Welds.

Tack welds used to secure alignment shall be either removed completely, when they have served their purpose, or their stopping and starting ends shall be properly prepared by grinding or other suitable means so that they may be satisfactorily incorporated into the final weld. Tack welds shall be made by qualified welders using qualified welding procedures. When tack welds are to become part of the finished weld, they shall be visually examined and defective tack welds removed.

NE-4232 Maximum Offset of Aligned Sections

(a) Alignment of sections shall be such that the maximum offset of the finished weld will not be greater than the applicable amount listed in Table NE-4232-1, where t is the nominal thickness of the thinner section at the joint.

(b) Joints in spherical vessels, joints within heads, and joints between cylindrical shells and hemispherical heads shall meet the requirements in Table NE-4232-1 for longitudinal joints.

NE-4232.1 Fairing of Offsets.

Any offset within the allowable tolerance provided above shall be faired to at least a 3:1 taper over the width of the finished weld, or, if necessary, by adding additional weld metal beyond what would otherwise be the edge of the weld. In addition, offsets greater than those stated in Table NE-4232-1 are acceptable provided the requirements of NE-3200 are met.

NE-4240 REQUIREMENTS FOR WELD JOINTS

NE-4241 Category A Weld Joints

Category A weld joints shall be full penetration butt welded joints. Joints that have been welded from one side with backing that has been removed, and those welded from one side without backing, are acceptable as full penetration welds provided the weld root side of the joints meet the requirements of NE-4424.

NE-4242 Category B Weld Joints

Category B weld joints shall be full penetration butt welded joints, except that NPS 2 (DN 50) and smaller pipe sizes may be socket welded. Joints made with consumable inserts or gas backup, or with metal backing rings or strips which are later removed, are acceptable as full penetration joints. When used, backing strips shall be continuous in cross section. Joints prepared with opposing lips to form an integral backing strip and joints with backing strips which are not later removed are acceptable.

NE-4243 Category C Weld Joints

Category C weld joints shall be full penetration joints, as shown in Fig. NE-4243-1 and Fig. NE-4243-2, except that socket welded flanges of NPS 2 (DN 50) and less and slip-on flanges may be used.

NE-4243.1 Flat Heads and Tubesheets With Hubs.

Hubs for butt welding to the adjacent shell, head, or other pressure part, as in Fig. NE-4243.1-1, shall not be machined from rolled plate. The component having the hub shall be forged in such a manner as to provide in the hub the full minimum tensile strength and elongation specified for the material, in a direction parallel to the axis of the vessel. Proof of this shall be furnished by a tension test specimen, subsize if necessary, taken in this direction and as close to the

Page 124

hub as is practical. In no case shall the height of the hub be less than 1.5 times the thickness of the pressure part to which it is welded.

Typical Unstayed Flat Heads and Side Plates of Rectangular Vessels

GENERAL NOTES [sketches (a) through (g)]:

- (1) For unstayed flat heads, see NE-3325; t_s , t_p , and t_w are as defined in NE-3325.1.
- (2) For definitions of a and b , see NE-3358.3.

Typical Bolted Flange Connections

Typical Nonpermissible Corner Joints

GENERAL NOTES [sketches (h) and (i)]:

FIG. NE-4243-2 ACCEPTABLE TYPES OF FULL PENETRATION WELD DETAILS FOR CATEGORY C JOINTS

FIG. NE-4243-2 ACCEPTABLE TYPES OF FULL PENETRATION WELD DETAILS FOR CATEGORY C JOINTS

GENERAL NOTE:

Not permissible if machined from rolled plate. The tension test specimen may be located, when possible, inside the forged hub, instead of outside, as shown.

FIG. NE-4243.1-1 TYPICAL FLAT HEADS

FIG. NE-4243.1-1 TYPICAL FLAT HEADS

NE-4244 Category D Weld Joints

Category D and similar weld joints shall be welded using one of the details of (a) through (g) below.

(a) *Butt Welded Nozzles.* Nozzles shall be attached by full penetration butt welds through either the vessel or the nozzle wall, as shown in Fig. NE-4244(a)-1. Backing strips, if used, may be left in place.

(b) *Full Penetration Corner Welded Nozzles.* Nozzles shall be attached by full penetration welds through the wall of the vessel or nozzle similar to those shown in Fig. NE-4244(b)-1. When complete joint penetration cannot be verified by

visual examination or other means permitted, backing strips or equivalent shall be used with full penetration welds deposited from only one side. Backing strips, if used, may be left in place.

(c) *Use of Deposited Weld Metal for Opening and Nozzles.* Nozzles shall be joined to the vessel by full penetration weld to built-up weld deposits which may be applied to either the vessel or nozzle wall as shown in Fig. NE-4244(c)-1. Backing strips, if used, may be left in place. Fillet welds shall be used in the attachment of nozzles only to provide a transition between the parts joined or to provide a seal. The fillet welds, when used, shall be finished by grinding to provide a smooth surface having a transition radius at its intersection with either part being joined.

(d) *Attachment of Nozzles Using Partial Penetration Welds.* Partial penetration welds shall meet the requirements of NE-3352.4(d) and NE-3359. Nozzles shall be attached as shown in Fig. NE-4244(d)-1, Fig. NE-4244(d)-2, or Fig. NE-4244(d)-3.

(e) *Attachment of Fittings With Internal Threads.* Internally threaded fittings shall be attached by a full penetration groove weld, or for NPS 2 (DN 50) and less by two fillet or partial penetration welds, one on each face of the vessel wall, or by a fillet groove weld from the outside only as shown in Fig. NE-4244(e)-1 sketch (c-3). Internally threaded fitting and bolting pads not exceeding 3 in. pipe size (DN 80), as shown in Fig. NE-4244(e)-2, may be attached to vessels having a wall thickness not greater than $\frac{3}{8}$ in. (10 mm) by a fillet weld, deposited from the outside only. The design requirements of NE-3352.4(e) shall be met for all vessels.

(f) *Tubed Connections.* Nozzles or tubes recessed into thick walled components or parts may be welded from only one side provided the requirements of NE-3352.4(f) are met. Typical connections are shown in Fig. NE-4244(f)-1.

(g) *Reinforcing Plates.* Reinforcing plates of nozzles attached to the outside of a vessel shall be provided with at least one telltale hole (maximum size $\frac{1}{4}$ in. pipe tap) that may be tapped for a preliminary compressed air and soapsuds test for tightness of welds. These telltale holes may be left open or may be plugged when the vessel is in service. If the holes are plugged, the plugging material used shall not be capable of sustaining pressure between the reinforcing plate and the vessel wall.

NE-4300 WELDING QUALIFICATIONS

NE-4310 GENERAL REQUIREMENTS

NE-4311 Types of Processes Permitted

Only those welding processes which are capable of producing welds in accordance with the welding procedure qualification requirements of Section IX and this Subsection may be used for welding pressure retaining material or attachments thereto. Any process used shall be such that the records required by NE-4320 can be prepared, except that records for stud welds shall be traceable to the welders and welding operators and not necessarily to each specific weld.

NE-4311.1 Stud Welding Restrictions.

Stud welding is acceptable only for nonstructural and temporary attachments (NE-4435). Studs shall be limited to 1 in. (25 mm) maximum diameter for round studs and an equivalent cross-sectional area for studs of other shapes when welding in the flat position and $\frac{3}{4}$ in. (19 mm) diameter for all other welding positions. Postweld heat treatment shall comply with NE-4600, except that time at temperature need not exceed $\frac{1}{2}$ hr, regardless of base material thickness. Welding procedure and performance qualification shall comply with the requirements of Section IX.

NE-4311.2 Capacitor Discharge Welding.

Capacitor discharge welding may be used for welding temporary attachments and permanent nonstructural attachments provided:

(a) temporary attachments are removed in accordance with the provisions of NE-4435(b); and

(b) the energy output for permanent nonstructural attachments such as strain gages and thermocouples is limited to 125 W-sec and the minimum thickness of the material to which the attachment is made is greater than 0.09 in. (2.3 mm); and

(c) a Welding Procedure Specification is prepared describing the capacitor discharge equipment, the combination of materials to be joined, and the technique of application; qualification of the welding procedure is not required.

NE-4311.4 Inertia and Continuous Drive Friction Welding.

Inertia and continuous drive friction welding shall not be used in the fabrication of containment vessels.

NE-4320 WELDING QUALIFICATIONS, RECORDS, AND IDENTIFYING STAMPS

NE-4321 Required Qualifications

(a) Each Certificate Holder is responsible for the welding done by his organization, and he shall establish the procedure and conduct the tests required by this Article and by Section IX in order to qualify both the welding procedures and the performance of welders and welding operators who apply these procedures.

(b) Procedures, welders, and welding operators used to join permanent or temporary attachments to pressure parts and to make permanent or temporary tack welds used in such welding shall also meet the qualification requirements of this Article.

(c) When making procedure test plates for butt welds, consideration shall be given to the effect of angular, lateral, and end restraint on the weldment. This applies particularly to material and weld metal of 80.0 ksi (552 MPa) tensile strength or higher and heavy sections of both low and high tensile strength material. The addition of restraint during welding may result in cracking difficulties that otherwise might not occur.

NE-4322 Maintenance and Certification of Records

The Certificate Holder shall maintain a record of his qualified welding procedures and of the welders and welding operators qualified by him, showing the date and results of tests and the identification mark assigned to each welder. These records shall be reviewed, verified, and signed by any authorized individual assigned by the Certificate Holder, and they shall be accessible to the Owner and to the Inspector.

Page 136

NE-4322.1 Identification of Joints by Welder or Welding Operator

(a) Each welder or welding operator shall apply the identification mark assigned to him by the Certificate Holder on or adjacent to all permanent welded joints or series of joints on which he welds. The marking shall be at intervals of 3 ft (0.9 m) or less and shall be done with either blunt nose continuous or blunt nose interrupted dot die stamps. As an alternative, the Certificate Holder shall keep a record of permanent welded joints in each item, and of the welders and welding operators used in making each of the joints.

(b) When a multiple number of permanent structural attachment welds, nonstructural welds, fillet welds, socket welds, welds of specially designed seals, weld metal cladding, hard surfacing and tube-to-tubesheet welds, are made on an item, the Certificate Holder need not identify the welder or welding operator who welded each individual joint, provided:

(1) the Certificate Holder maintains a system that will identify the welders or welding operators who made such welds on each item so that the Inspector can verify that the welders or welding operators were all properly qualified;

(2) the welds in each category are all of the same type and configuration and are welded with the same welding procedure specification.

(c) The identification of welder or welding operator is not required for tack welds.

NE-4323 Welding Prior to Qualifications

No welding shall be undertaken until after the welding procedures which are to be used have been qualified. Only welders and welding operators who are qualified in accordance with NE-4320 and Section IX shall be used.

NE-4324 Transferring Qualifications

The welding procedure qualifications and the performance qualification tests for welders and welding operators conducted by one Certificate Holder shall not qualify welding procedures and shall not qualify welders or welding operators to weld for any other Certificate Holder, except as provided in Section IX, QW-201 and QW-300.2.

NE-4330 GENERAL REQUIREMENTS FOR WELDING PROCEDURE QUALIFICATION TESTS

NE-4331 Conformance to Section IX Requirements

All welding procedure qualification tests shall be in accordance with the requirements of Section IX as supplemented by the requirements of this Article.

NE-4333 Heat Treatment of Qualification Welds of Ferritic Material

Postweld heat treatment of procedure qualification welds shall conform to the applicable requirements of NE-4600 and Section IX. The postweld heat treatment time at temperature shall be at least 80% of the maximum time to be applied to the weld material. The postweld heat treatment total time may be applied in one heating cycle.

NE-4334 Preparation of Test Coupons and Specimens

(a) Removal of test coupons from the test weld and the dimensions of specimens made from them shall conform to the requirements of Section IX, except that the removal of impact test coupons and the dimensions of impact test specimens shall be in accordance with (b) below.

(b) Weld deposit of each process in a multiple process weld shall, where possible, be included in the impact test specimens. When each process cannot be included in the full-size impact test specimen at the $1/4t$ location required by this

Section, additional full-size specimens shall be obtained from locations in the test weld that will ensure that at least a portion of each process has been included in full-size test specimens. As an alternative, additional test welds can be made with each process so that full-size specimens can be tested for each process.

NE-4334.1 Coupons Representing the Weld Deposits.

Impact specimen and testing methods shall conform to NE-2321. The impact specimen shall be located so that the longitudinal axis of the specimen is at least $\frac{1}{4}t$, and where the thickness of the test assembly permits, not less than $\frac{3}{8}$ in. (10 mm) from the weld surface of the test assembly. In addition, when the postweld heat treatment temperature exceeds the maximum temperature specified in NE-4620, and the test assembly is cooled at an accelerated rate, the longitudinal axis of the specimen shall be a minimum of t from

Page 137

the edge of the test assembly. The specimen shall be transverse to the longitudinal axis of the weld with the area of the notch located in the weld. The length of the notch of the Charpy V-notch specimen shall be normal to the surface of the weld. Where drop weight specimens are required, the tension surface of the specimen shall be oriented parallel to the surface of the test weld assembly.

NE-4334.2 Coupons Representing the Heat Affected Zone.

Where impact tests of the heat affected zone are required by NE-4335.2, specimens shall be taken from the welding procedure qualification test assemblies in accordance with (a) through (c) below.

(a) If the qualification test material is in the form of a plate or a forging, the axis of the weld shall be oriented either parallel or perpendicular to the principal direction of rolling or forging.

(b) The heat affected zone impact test specimens and testing methods shall conform to the requirements of NE-2321.2. The specimens shall be removed from a location as near as practical to a depth midway between the surface and center thickness. The coupons for heat affected zone impact specimens shall be taken transverse to the axis of the weld and etched to define the heat affected zone. The notch of the Charpy V- notch specimen shall be cut approximately normal to the material surface in such a manner as to include as much heat affected zone as possible in the resulting fracture. Where the material thickness permits, the axis of a specimen may be inclined to allow the root of the notch to align parallel to the fusion line. When a grain refining heat treatment is not performed on welds made by the electroslag or electrogas welding process, the notch for the impact specimens shall be located in the grain coarsened region.

(c) For the comparison of heat affected zone values with base material values [NE-4335.2(b)], Charpy V-notch specimens shall be removed from the unaffected base material at approximately the same distance from the base material surface as the heat affected zone specimens. The axis of the unaffected base material specimens shall be parallel to the axis of the heat affected zone specimens, and the axis of the notch shall be normal to the surface of the base material.

NE-4335 Impact Test Requirements

When materials are required to be impact tested per NE-2300, impact tests of the weld metal and heat affected zone shall be performed in accordance with the following subparagraphs. Exemption from impact testing under NE-2311(a)(8) does not apply for weld metal unless the specific weld metal used is included in Table NE-2311(a)-1. Exemption from impact testing of the heat affected zone of those base materials exempted by NE-2311(a)(8) is not permitted. The weld procedure qualification impact test specimens shall be prepared and tested in accordance with the applicable requirements of NE-2330 and NE-4334. Retests in accordance with the provisions of NE-2350 are permitted.

NE-4335.1 Impact Tests of Weld Metal

(a) Impact tests of the weld metal shall be required for welding procedure qualification tests for production weld joints exceeding $\frac{5}{8}$ in. (16 mm) in thickness when the weld is made on the surface or penetrates the base material that requires impact testing in accordance with NE-2310. In addition, such testing of the weld metal is required for the welding procedure qualification tests for any weld repair to base material that requires impact testing in accordance with NE-2310, regardless of the depth of the repair. Exemption from impact testing under NE-2311(a)(8) does not apply for weld metal of welding procedure qualification tests for either production weld joints or base material repairs, unless the

specific weld metal used is included in Table NE-2311(a)-1.

(b) The impact test requirements and acceptance standards for welding procedure qualification weld metal shall be the same as specified in NE-2330 for the base material to be welded or repaired. Where two materials which have different fracture toughness requirements are to be joined by welding, the test requirements and acceptance standards of either material may be used for the weld metal, except where otherwise specified by NCA-1230 or other parts of this Section.

(c) A Welding Procedure Specification qualified to the impact testing requirements of Subsection NB or Subsection NC may be accepted as an alternative to the Welding Procedure Specification impact testing requirements of this Subsection.

NE-4335.2 Impact Tests of Heat Affected Zone

(a) Charpy V-notch tests of the heat affected zone of the welding procedure qualification test assembly are required whenever the thickness of the weld exceeds $\frac{5}{8}$ in. (16 mm) and either of the base materials requires impact testing in accordance with the rules of NE-2310.

The only exceptions to the requirements are the following:

(1) the qualification for welds in P-No. 1 materials that are postweld heat treated and made by any process other than electroslog, electrogas, or thermit;

(2) the qualification for weld deposit cladding or hard-facing on any base material.

Page 138

(b) Impact testing of the procedure qualification test heat affected zone, where required by NE-4335, shall be conducted in accordance with (b)(1) through (b)(3) or (b)(4) through (b)(6), and (c) below, if applicable.

(1) For tests of welding procedure qualifications for materials that require tests in accordance with NE-2332.1 and NE-2333.1, when applicable, three Charpy V-notch heat affected zone and three Charpy V-notch unaffected base material specimens shall be tested at a temperature in accordance with NE-2331(a)(1). The Charpy V-notch impact test of the unaffected base material shall meet the requirements of Table NE-2332.1-1 or Table NE-2332.1-2, and Table NE-2333.1-1, if applicable. If the average toughness value of the three heat affected zone specimens is equal to or greater than the average value of the unaffected base material Charpy V-notch specimens, the qualification test shall be considered acceptable, the values and testing temperatures shall be recorded on the Welding Procedure Qualification Record, and the production base material impact tests may be conducted at temperatures in accordance with NE-2331.

(2) If the heat affected zone Charpy V-notch average toughness value of (b)(1) above is less than the unaffected base material value and the qualification test meets the other criteria of acceptance, the Charpy V-notch test results may be recorded on the Welding Procedure Qualification Record. In this case, either production base material impact tests shall be conducted 30°F lower than required by NE-2331 or data which will provide a testing temperature reduction for the production base material below that of NE-2331, or an increase in the lowest service temperature for the base material for which the welding procedure is being qualified shall be obtained in accordance with (b)(3) below and included. Alternatively, the welding procedure qualification may be rewelded and retested.

(3) The data for use in (b)(2) above shall be developed by performing additional Charpy V-notch tests on either the welding procedure qualification test heat affected zone or the unaffected base material or both at temperatures which provide toughness values that meet or exceed those required for the thickness or thickness-strength combination of the material to be welded in production. The average toughness values for the heat affected zone and unaffected base material shall be plotted on a property-temperature chart. The temperature at which these two sets of data exhibit a common acceptable value of toughness for the production thickness or thickness-strength combination involved shall be determined. The determined temperature for the unaffected base material shall be subtracted from the similarly determined temperature for the heat affected zone. This difference, if a positive number, shall be used in (b)(2) above as the adjustment temperature. The welding procedure adjustment temperature shall be added to the highest lowest service temperature established by the tests of NE-2332.1 for all of the base material to be welded by this procedure in production. If the temperature difference is zero or a negative number, no adjustment is required for the base material to be welded in production, and the minimum temperature established by the tests for NE-2332.1 will still apply as stated in (b)(1) above. Where the actual lowest service temperature is not required for the production material to be

welded (for example, where a testing temperature is established by the Design Specification to determine that the material has adequate toughness to meet the requirements at the specified test temperature), the adjustment temperature determined by the curves shall be used to establish a reduction in the specified testing temperature for the production material. The adjustment temperature shall be used to lower the specified testing temperature for any production material upon which the procedure will be used.

(4) For tests of welding procedure qualifications for materials that require tests in accordance with NE-2332.2, three Charpy V-notch heat affected zone specimens and three Charpy V-notch unaffected base material specimens shall be tested at a temperature lower than or equal to the lowest service temperature. The Charpy V-notch impact tests of the unaffected base material shall meet or exceed the applicable Over $2\frac{1}{2}$ in. (64 mm) thickness requirements of Table NE-2332.1-1 or Table NE-2332.1-2, and Table NE-2333.1-1, if applicable. If the average toughness value of the three heat affected zone specimens is equal to or greater than the average value for the unaffected base material Charpy V-notch specimens, the qualification test shall be considered acceptable. The values and testing temperature shall be recorded on the Welding Procedure Qualification Record.

(5) If the heat affected zone Charpy V-notch average toughness value of (b)(4) above is less than the unaffected base material value, and the qualification test meets the other criteria of acceptance, the Charpy V-notch test results may be recorded on the Welding Procedure Qualification Record. In this case, either production base material impact tests shall be conducted 30°F (17°C) lower than required by NE-2331 or data which will provide a testing temperature reduction for the production base material below that of NE-2331, or an increase in the lowest service temperature for the base material for which the welding procedure is being qualified shall be obtained in accordance with

Page 139

(b)(6) below and included. Alternatively, the welding procedure qualification may be rewelded and retested.

(6) The data for use in (b)(5) above shall be developed by performing additional Charpy V-notch tests on either or both of the welding procedure qualification heat affected zone and unaffected base material at temperatures which provide values equal to or greater than the applicable Over $2\frac{1}{2}$ in. (64 mm) thickness requirements of Table NE-2332.1-1 or Table NE-2332.1-2, and Table NE-2333.1-1, if applicable. The average toughness values for the heat affected zone and the unaffected base material shall be plotted on a property-temperature chart. The temperature at which these two sets of data exhibit a common toughness value equal to or greater than the applicable Over $2\frac{1}{2}$ in. (64 mm) thickness requirements of Table NE-2332.1-1 or Table NE-2332.1-2, and Table NE-2333.1-1, if applicable, shall be determined. The determined temperature for the unaffected base material shall be subtracted from the similarly determined temperature for the heat affected zone. This difference, if a positive number, shall be used in (b)(5) above as the adjustment temperature. The adjustment temperature shall be added to the highest T_{NDT} established by the tests of NE-2332.2 for all of the base materials to be welded by this procedure in production. If the temperature difference is zero or a negative number, no adjustment is required for the base material to be welded in production, and the minimum temperature established by the tests for NE-2332.2 will still apply as stated in (b)(4) above.

Where the actual T_{NDT} is not required for the production material to be welded (for example, where a testing temperature is established by the Design Specification to determine that the T_{NDT} is at or below the specified temperature), the adjustment temperature determined by the curves shall be used to establish a reduction in the specified testing temperature for the production material. The adjustment temperature shall be used to lower the specified testing temperature for any production material upon which the procedure will be used.

(c) Should the unaffected base material Charpy V-notch impact test results fail to meet the applicable requirements referenced in (b)(1) or (b)(4) above, additional unaffected base material Charpy V-notch impact tests shall be tested at higher temperatures until the applicable requirements are met. Charpy V-notch impact tests of the heat affected zone shall be tested at the same temperature at which acceptable unaffected base material properties were achieved. The rules governing the average toughness of the heat affected zone relative to the average toughness of the unaffected base material shall be followed as in (b)(1) through (3), or (b)(4) through (6), as applicable, to determine the data which are to be recorded on the Welding Procedure Qualification Record.

(d) A Welding Procedure Specification qualified to the impact testing requirements of Subsection NB or Subsection NC may be accepted as an alternative to the Welding Procedure Specification impact testing requirements of this Subsection.

NE-4336 Qualification Requirements for

Built-Up Weld Deposits

Built-up weld deposits for base metal reinforcement shall be qualified in accordance with the requirements of NE-4331 through NE-4335.

NE-4340 PERFORMANCE QUALIFICATION OF WELDERS FOR CLAD MATERIAL

NE-4341 General Requirements

A welder who has passed a test on composite welds in clad plate, as provided in NE-4341.1, or as part of a procedure qualification test, as provided in NE-4429.1(a), is qualified for welding base metal and lining or cladding material separately. Likewise, a welder who has qualified on base metal and lining or cladding material separately is qualified to make composite welds. Qualification on both base plate and lining or cladding material is required only of welders who weld both materials.

NE-4341.1 Requirements for Composite Materials.

Performance qualification tests shall be made in accordance with Section IX by preparing test plates from clad material having the same P-Numbers in QW-442 as that of the base plate and cladding material to be used in construction, and having the same F-Number in QW-432 as the filler metal that will be used in construction. When the cladding material is not listed in QW-442, qualification shall be made on the same grade as used in the vessel. Heat treatment is not required but is permitted if the welder's work or construction is to be heat treated.

NE-4341.2 Requirements for Corrosion Resistant Welds.

Performance qualification tests for welding corrosion resistant materials shall be the same as the procedure qualification tests described in NE-4331.

Page 140

NE-4400 RULES GOVERNING MAKING, EXAMINING, AND REPAIRING WELDS

NE-4410 PRECAUTIONS TO BE TAKEN BEFORE WELDING

NE-4411 Identification, Storage, and Handling of Welding Materials

Each Certificate Holder is responsible for control of the welding electrodes and other material which is used in the fabrication and installation of components (NE-4120). Suitable identification, storage, and handling of electrodes, flux, and other welding material shall be maintained. Precautions shall be taken to minimize absorption of moisture by electrodes and flux.

NE-4412 Cleanliness and Protection of Welding Surfaces

The method used to prepare the base metal shall leave the weld preparation with reasonably smooth surfaces. The surfaces for welding shall be free of scale, rust, oil, grease, and other deleterious material. The work shall be protected from deleterious contamination and from rain, snow, and wind during welding. Welding shall not be performed on wet surfaces.

NE-4420 RULES FOR MAKING WELDED JOINTS

NE-4421 Backing Rings

Backing rings shall conform to the requirements of NE-4240. The material for backing rings, when used, shall be compatible with the base metal. Permanent backing rings, when permitted by NE-4240, shall be continuous, and any splices shall be made by full penetration welds. Spacer pins shall not be incorporated into the welds.

NE-4422

NE-4422 Peening

Controlled peening may be performed to minimize distortion. Peening shall not be used on the initial layer root of the weld metal, nor on the final layer, unless the weld is postweld heat treated in accordance with NE-4600.

NE-4423 Miscellaneous Welding Requirements

(a) Before applying weld metal on the second side to be welded, the root of full penetration double welded joints shall be prepared by suitable methods such as chipping, grinding, or thermal gouging, except for those processes of welding by which proper fusion and penetration are otherwise obtained and demonstrated to be satisfactory by welding procedure qualification.

(b) If the welding is stopped for any reason, extra care shall be taken in restarting to get the required penetration and fusion. For submerged arc welding, chipping out a groove in the crater is recommended.

(c) Where single welded joints are used, particular care shall be taken in aligning and separating the components to be joined so that there will be complete penetration and fusion at the bottom of the joint for its full length.

NE-4424 Surfaces of Welds

As-welded surfaces are permitted. However, the surface of welds shall be sufficiently free from coarse ripples, grooves, overlaps, abrupt ridges, and valleys to meet (a) through (e) below.

(a) The surface condition of the finished weld shall be suitable for the proper interpretation of radiographic and other required nondestructive examinations of the welds. In those cases where there is a question regarding the surface condition on the interpretation of a radiographic film, the film shall be compared to the actual weld surface for interpretation and determination of acceptability.

(b) Reinforcements are permitted in accordance with NE-4426.

(c) Undercuts shall not exceed $\frac{1}{32}$ in. (0.8 mm) and shall not encroach on the required section thickness.

(d) Concavity on the root side of a single welded circumferential butt weld is permitted when the resulting thickness of the weld meets the requirements of NE-3000.

(e) If the surface of the weld requires grinding to meet the above criteria, care shall be taken to avoid reducing the weld or base material below the required thickness.

NE-4425 Welding Components of Different Diameters

When components of different diameters are welded together, there shall be a gradual transition between the two surfaces in accordance with NE-3361. The length of the transition may include the weld.

Page 141

NE-4426 Reinforcement of Welds

The surface of the reinforcement of all butt welded joints in vessels may be flush with the base material or may have uniform crowns. The height of reinforcement on each face of the weld shall not exceed the following thickness:

Nominal Thickness, in.	Maximum Reinforcement, in.
Up to 1, incl.	$\frac{3}{32}$
Over 1 through 2, incl.	$\frac{1}{8}$
Over 2 through 3, incl.	$\frac{5}{32}$
Over 3 through 4, incl.	$\frac{7}{32}$
Over 4 through 5, incl.	$\frac{1}{4}$
Over 5	$\frac{5}{16}$

NE-4427 Shape and Size of Fillet Welds

Fillet welds may vary from convex to concave. The shape and size of the weld shall be in accordance with the requirements of Fig. NE-4427-1. A fillet weld in any single continuous weld may be less than the specified fillet weld dimension by not more than $\frac{1}{16}$ in. (1.6 mm), provided that the total undersize portion of the weld does not exceed 10% of the length of the weld. Individual undersize weld portions shall not exceed 2 in. (51 mm) in length. In making socket welds, a gap as shown in Fig. NE-4427-1 shall be provided prior to welding. The gap need not be present nor be verified after welding.

NE-4428 Seal Welds of Threaded Joints

Where seal welding of threaded pipe joints is performed, the exposed threads shall be either removed entirely or covered with weld metal.

NE-4429 Welding of Clad Parts¹

The joint types and welding procedures used for cladding shall be such as to prevent the formation of brittle weld composition.

NE-4429.1 Groove Welds in Clad Plate

(a) The requirements in Section IX for procedure qualification shall be modified as follows for groove welds in clad plate.

¹ Welds that are exposed to corrosive action should have a resistance to corrosion that is not substantially less than that of the cladding. The use of filler metal that will deposit weld metal which is similar to the composition of the cladding material is recommended. If weld metal of different composition is used, it should have properties compatible with the application.

(1) The requirements in QW-403 and QW-404 shall apply separately to the base plate and to the cladding.

(2) The thicknesses specified in Table QW-451 shall apply to the total thickness of clad plate.

(3) For material not included in Table QW-422, the material used in the test plate shall be within the range of chemical composition of that to be used in construction.

(b) The welding procedure for groove welds in integrally clad plate shall be qualified as provided in (a) above when any part of the cladding thickness of the clad plate is included in the design calculations in accordance with NE-3122.4 (b). When the cladding thickness is not included in the design calculations, the procedure for groove welds may be qualified as in (a) above or the weld in the base plate joint may be qualified by itself in accordance with the rules in Section IX and the weld in the cladding joint by itself in accordance with NE-4429.3.

NE-4429.2 Alloy Welds in Base Metal.

Groove joints in base-metal plates and parts may be made with corrosion resistant alloy-steel filler metal, or groove joints may be made between corrosion resistant alloy steel and carbon or low alloy steel, provided the welding procedure and the welders have been qualified in accordance with the requirements of Section IX for the combination of materials used. Some applications of this rule are base metal welded with alloy-steel electrodes and alloy nozzles welded to shells.

NE-4429.3 Corrosion Resistant Weld Deposits.

Construction in which deposits of corrosion resistant alloy weld metal are applied as a protective covering on the surface of base metal plates and parts and over welded base metal joints, whether adjacent or not to the edges of lining sheets or cladding material, shall be qualified in accordance with the rules given in (a) through (f) below.

(a) The qualification test plate shall consist of a base plate not less than 6 in. (152 mm) long, 3 in. (76 mm) wide, and $\frac{1}{4}$ in. (6 mm) thick, to which are clamped or bonded two strips of lining or cladding material separated by a gap left in the lining or a groove cut in the cladding. The gap or groove shall run lengthwise of the test plate, approximately midway of the plate width. The nominal thickness of the lining or cladding shall be within 20% plus or minus of the thickness to be used in construction.

(b) The requirements of Section IX, QW-403 and QW-404, shall apply separately to the base plate and the lining or cladding. For material not included in Table QW-422, the material used in the test plate shall

Page 142

be within the range of chemical composition of that to be used in construction.

FIG. NE-4427-1 FILLET AND SOCKET WELD DETAILS AND DIMENSIONS

FIG. NE-4427-1 FILLET AND SOCKET WELD DETAILS AND DIMENSIONS

(c) The width of gap shall be not less than twice the nominal thickness of the lining or cladding and not less than the maximum gap to be used in construction, but need not be greater than $\frac{3}{4}$ in. (19 mm) in order to qualify welding procedures in which corrosion resistant weld metal is deposited in contact with base metal and adjacent lining or cladding material on two sides of a gap, as in welding the joints in linear sheets or clad plates.

(d) The width of a gap shall be not less than $\frac{3}{4}$ in. (19 mm) in order to qualify welding procedures in which corrosion resistant weld metal is deposited in contact with base metal with lining or cladding material on one side only, as in layering corrosion resistant weld metal on flange facings or in making fillet welds.

(e) The weld joint shall be made between the edges of the lining or cladding material by the procedure to be used in construction. The cooling of the test plate and any subsequent heat treatment shall follow the procedure to be used in construction.

(f) The tests to qualify the welding procedure shall be performed on two longitudinal bend test specimens that conform to the dimensions and other requirements of Section IX, QW-161 and QW-462.3(b). The specimens shall be tested in accordance with, and meet the requirements of, QW-162 and QW-163.

NE-4429.4 Fillet Welds.

Fillet welds of corrosion resistant metal deposited in contact with two materials of dissimilar composition may be used for connection attachments under the limitations of NE-3359. The qualification of the welding procedures and welders to be used on fillet welds for a given combination of materials and alloy weld metal shall be made in accordance with NE-4429.3 or, alternatively, by the rules prescribed in Section IX.

NE-4430 WELDING OF ATTACHMENTS

NE-4431 Materials for Attachments

Nonpressure-retaining attachments (NE-1132.1) welded to the containment vessel shall be of materials which meet the requirements of NE-2190. Materials for pressure retaining attachments shall meet the requirements of NE-2120.

NE-4432 Welding of Structural Attachments

The rules of NE-4321 governing welding qualifications shall apply to the welding of structural attachments to pressure retaining material.

NE-4433 Structural Attachments

Structural attachments shall conform reasonably to the curvature of the shell or surface to which they are attached, and may be attached by either full penetration, fillet, or partial penetration continuous or intermittent welds.

NE-4434 Welding of Internal Structural Supports to Clad Components

Internal structural supports on cladding surfaces shall be welded to the base metal and not to the cladding, except for weld overlay cladding.

NE-4435 Welding of Nonstructural and Temporary Attachments and Their Removal

(a) Nonstructural attachments (NE-1132.1) welded to the pressure retaining portion of the containment vessel need not comply with NE-2000 and may be welded with continuous or intermittent fillet or partial penetration welds, provided the requirements of (1) through (4) below are met:

- (1) the welding procedure and the welders have been qualified in accordance with NE-4321;
- (2) the material is identified and is compatible with the material to which it is attached;
- (3) the welding material is identified and compatible with the materials joined;

- (4) the welds are postweld heat treated when required by NE-4620.
- (b) Removal of temporary attachments shall be accomplished as follows:
- (1) The temporary attachment is completely removed in accordance with the procedures of NE-4211.
- (2) As an alternative to (a)(4) above, postweld heat treatment may be deferred until after removal of the attachment.

NE-4437 Attachment of Stiffening Rings to Shell

(a) Stiffening rings, when used, may be placed on the inside or outside of a vessel and shall be attached

Page 144

to the shell by welding or bolting. The ring shall be in contact with the shell.

**FIG. NE-4437(b)-1 ATTACHMENT
OF STIFFENING
RINGS TO SHELL**

FIG. NE-4437(b)-1 ATTACHMENT OF STIFFENING RINGS TO SHELL

(b) Stiffening rings may be attached to the shell either by continuous or intermittent welding. The total length of the intermittent welding on each side of the stiffening ring shall be:

(1) not less than one-half the outside circumference of the vessel for rings on the outside; and

(2) not less than one-third of the circumference of the vessel for rings on the inside. Acceptable arrangements and spacing of intermittent welds are shown in Fig. NE-4437(b)-1. Welds on opposite sides of the stiffener may be either staggered or in-line as indicated.

(c) All welding of stiffening rings shall comply with the requirements of this Subsection. In areas where a corrosion allowance is specified in the Design Specification, stiffening rings shall be attached to the shell with a continuous fillet, seal, or full penetration weld.

NE-4450 REPAIR OF WELD METAL DEFECTS

NE-4451 General Requirements

Defects in weld metal detected by the examinations required by NE-5000, or by the tests of NE-6000, shall be eliminated and when necessary repaired.

NE-4452 Elimination of Surface Defects

Weld metal surface defects may be removed by grinding or machining and not repaired by welding provided that the requirements of (a) through (c) below are met:

(a) the remaining thickness of the section is not reduced below that required by NE-3000;

(b) the depression, after defect elimination, is blended uniformly into the surrounding surface;

(c) the area is examined by a magnetic particle or liquid penetrant method in accordance with NE-5110 after blending and meets the acceptance standards of NE-5300 to ensure that the defect has been removed or the indication reduced to an acceptable limit. Defects detected by the visual or volumetric method and located on an interior surface need only be reexamined by the method which initially detected the defect when the interior surface is inaccessible for surface examination.

NE-4453 Requirements for Making Repairs to Welds

Excavations in weld metal, when repaired by welding, shall meet the requirements of the following subparagraphs.

NE-4453.1 Defect Removal.

Defects may be removed by mechanical means or by thermal gouging processes. The area prepared for repair shall be examined by a liquid penetrant or magnetic particle method in accordance with NE-5110 and meet the acceptance standards of NE-5340 or NE-5350. This examination is not required where defect elimination removes the full thickness of the weld and where the backside of the weld joint is not accessible for removal of examination materials.

NE-4453.2 Requirements for Welding Material, Procedures, and Welders.

The weld repair shall be made using welding material, welders, and welding procedures qualified in accordance with NE-4125 and NE-4300.

NE-4453.3 Blending of Repaired Areas.

After repair the surface shall be blended uniformly into the surrounding surface.

NE-4453.4 Examination of Repair Welds.

The examination of a weld repair shall be repeated as required for the original weld, except that it need only be reexamined by the liquid penetrant or magnetic particle method when the unacceptable indication was originally detected by the liquid penetrant or magnetic particle

Page 145

method and when the repair cavity does not exceed the following:

- (a) $\frac{1}{3}t$ for $t \leq \frac{3}{4}$ in. (19 mm)
- (b) $\frac{1}{4}$ in. for $\frac{3}{4}$ in. (19 mm) $< t \leq 2\frac{1}{2}$ in. (64 mm)
- (c) the lesser of $\frac{3}{8}$ in. (10 mm) or 10% t for $t > 2\frac{1}{2}$ in. (64 mm)

where t equals the thickness of the weld.

NE-4453.5 Heat Treatment of Repaired Areas.

The area shall be heat treated in accordance with NE-4620.

NE-4454 Inserted Strips in Clad Material

The thickness of inserted strips used to restore cladding at joints shall be equal to that of the nominal minimum thickness of cladding specified for the plates backed, if necessary, with corrosion resistant weld metal deposited in the groove to bring the insert flush with the surface of the adjacent cladding.

NE-4600 HEAT TREATMENT

NE-4610 WELDING PREHEAT REQUIREMENTS

NE-4611 When Preheat Is Necessary

The need for and temperature of preheat are dependent on a number of factors, such as the chemical analysis, degree of restraint of the parts being joined, elevated temperature, physical properties, and material thicknesses. Some practices used for preheating are given in Appendix D as a general guide for the materials listed by P-Numbers of Section IX. It is cautioned that preheating suggested in Appendix D does not necessarily ensure satisfactory completion of the welded joint and that the preheating requirements for individual materials within the P-Number listing may be more or less restrictive. The Welding Procedure Specification for the material being welded shall specify the minimum preheating requirements under the welding procedure qualification requirements of Section IX.

NE-4612 Preheating Methods

Preheat for welding or thermal cutting, when employed, may be applied by any method which does not harm the base material or any weld metal already applied, or which does not introduce deleterious material into the welding area which is harmful to the weld.

NE-4613 Interpass Temperature

Consideration shall be given to the limitations of interpass temperatures for quenched and tempered material to avoid detrimental effects on the mechanical properties.

NE-4620 POSTWELD HEAT TREATMENT

NE-4621 Heating and Cooling Methods

Postweld heat treatment (PWHT) may be accomplished by any suitable methods of heating and cooling, provided the required heating and cooling rates, metal temperature, metal temperature uniformity, and temperature control are maintained.

NE-4622 PWHT Time and Temperature Requirements

NE-4622.1 General Requirements.²

The requirements for postweld heat treatment are given in (a), (b), and (c) below.

(a) Except as otherwise permitted in NE-4622.7, all welds, including repair welds, shall be postweld heat treated. During postweld heat treatment, the metal temperatures shall be maintained with the temperature ranges and for the minimum holding times specified in Table NE-4622.1-1, except as otherwise permitted in NE-4622.4(c). P-Number groups in Table NE-4622.1-1 are in accordance with Section IX, QW-420. Except as provided in NE-4624.3, PWHT shall be performed in temperature-surveyed and -calibrated furnaces, or PWHT shall be performed with thermocouples in contact with the material or attached to blocks in contact with the material.

(b) Unless exempted in Table NE-4622.7(b)-1, all doors, nozzles, opening frames, and similar welded construction shall be welded into a portion of the shell plate or plates, and the welded subassembly shall be postweld heat treated prior to welding into the shell.

(c) The requirements of the following subparagraphs shall also apply.

2 Any postweld heat treatment time which is anticipated to be applied to the material or item after it is completed shall be specified in the Design Specification. The Certificate Holder shall include this time in the total time at temperature specified to be applied to the test specimens.

NE-4622.2 Time-Temperature Recordings.

Time-temperature recordings of all postweld heat treatments shall be made available for review by the Authorized Inspector. Identification on the time-temperature recording shall be to the weld, part, or vessel. A summary

Page 146

of the time-temperature recording may be provided for permanent records in accordance with NCA-4134.17.

TABLE NE-4622.1-1
MANDATORY REQUIREMENTS FOR POSTWELD HEAT TREATMENT (PWHT) OF WELDS¹

P-Number (Sect. IX, QW-420)	Holding Temperature Range, °F [Note (2)]	Minimum Holding Time at Temperature For Weld Thickness (Nominal)		
		½ in. or less	Over ½ in. to 2 in.	Over 2 in.
1	1100–1250	30 min	1 hr/in.	2 hr plus 15 min each additional inch over 2 in.
----- 8, 34, 42, 43, 45	PWHT neither required nor prohibited			

NOTES:

(1) Exemption to the mandatory requirements of this Table are defined in NE-4622.7.

(2) All temperatures are metal temperatures.

TABLE NE-4622.1-1 MANDATORY REQUIREMENTS FOR POSTWELD HEAT TREATMENT (PWHT) OF WELDS¹

NE-4622.3 Definition of Nominal Thickness Governing PWHT.

Nominal thickness in Table NE-4622.7(b)-1 is the thickness of the weld, the pressure retaining material for structural attachment welds or the thinner of the pressure retaining materials being joined, whichever is least. It is not intended that nominal thickness include material provided for forming allowance, thinning, or mill overrun when the excess material does not exceed $\frac{1}{8}$ in. (3.2 mm). For fillet welds the nominal thickness is the throat thickness, and for partial penetration and material repair welds the nominal thickness is the depth of the weld groove or penetration.

NE-4622.4 Holding Times at Temperature

(a) The holding time at temperature as specified in Table NE-4622.1-1 shall be based on the nominal thickness of the weld. The holding time need not be continuous. It may be an accumulation of the times of multiple postweld heat treatment cycles.

(b) Holding time at temperature in excess of the minimum requirements of Table NE-4622.1-1 may be used, provided that specimens so heat treated are tested in accordance with NE-2200, NE-2400, and NE-4300.

(c) Alternatively, when it is impractical to postweld heat treat at the temperature range specified in Table NE-4622.1-1, it is permissible to perform the postweld heat treatment of certain materials at lower temperatures for longer periods of time in accordance with Table NE-4622.4(c)-1 and (1) below.

(1) Base materials certified in accordance with NE-2200 may be postweld heat treated at these lower minimum temperatures and increased minimum holding times without recertification. Postweld heat treatment at these lower minimum temperatures and increased minimum holding times may also be the tempering operation, provided a higher tempering temperature is not required by the material specification.

**TABLE 4622.4(c)-1
ALTERNATIVE HOLDING TEMPERATURES
AND TIMES¹**

Material P-Numbers	Alternative Holding Temperature Range, °F	Alternative Minimum¹ Holding Times
1	1050	2 hr/in. thick
1	1000	4 hr/in. thick

NOTE:

(1) All other requirements of NE-4622 shall apply.

TABLE NE-4622.4(c)-1 ALTERNATIVE HOLDING TEMPERATURES AND TIMES¹

NE-4622.5 PWHT Requirements When Different P-Number Materials Are Joined.

Postweld heat treatment is not required when joining P-No. 1 material 1½ in. (38 mm) or less in thickness to P-No. 8, P-No. 42, P-No. 43, or P-No. 45 materials with electrodes that produce austenitic or non-air-hardening nickel-chromium-iron deposits.

NE-4622.6 PWHT Requirements for Nonpressure-Retaining Parts.

When nonpressure-retaining material is welded to pressure retaining material, the postweld heat treatment temperature range of the pressure retaining material shall control.

NE-4622.7 Exemptions to Mandatory Requirements.

Postweld heat treatment in accordance with this Subarticle is not required for:

(a) nonferrous materials;

(b) welds exempted in Table NE-4622.7(b)-1;

Page 147

Page 148

TABLE NE-4622.7(b)-1
EXEMPTIONS TO MANDATORY PWHT¹

98

P-Number, (Sec. IX, QW-20)	Type of Weld [Note (6)]	Nominal Thickness (NE-4622.3)	Max. Reported Carbon, % [Note (7)]	Min. Preheat Required, °F
1	All welds where the materials being joined are 1½ in. and less, exclusive of welds joining nozzles or penetrations with an I.D. greater than 2 in. to the vessel shell	1¼ in. or less Over 1¼ in. to 1½ in. ¾ in. or less Over ¾ in. to 1½ in.	0.30 or less 0.30 or less Over 0.30 Over 0.30	... 200 ... 200
	All welds joining nozzles and penetrations with an I.D. greater than 2 in. to the vessel shell provided all of the following are satisfied: (1) the shell thickness does not exceed 1½ in., (2) the size does not exceed NPS 12, (3) the ratio of major to minor diameter of non-circular openings does not exceed 1.15, and (4) the weld is at least 1.0 (R) ^{1/2} from any other non-postweld heat treated weld in the vessel shell.	1¼ in. or less Over 1¼ in. to 1½ in. ¾ in. or less Over ¾ in. to 1½ in.	0.30 or less 0.30 or less Over 0.30 Over 0.30	... 200 ... 200
	All welds in material over 1½ in., exclusive of welds joining nozzles or penetrations to the vessel shell	¾ in. or less	...	200
	All welds, including repair welds in material greater than 1½ in., but equal to or less than 1¾ in. exclusive of welds joining nozzles or penetrations to the vessel shell [Note (2)]	1¾ in. or less	0.24	200
	All welds joining nozzles or penetrations with a nominal I.D. of 2 in. and less	¾ in. or less	...	200
	Repairs to welds in subassemblies postweld heat treated as required by NE-4622.1(b) with the total accumulated repair length of any weld not exceeding 25% of the original weld length	¾ in. or less	...	200
1 Gr. 1 or Gr. 2	Cladding or repair of cladding [Note (3)] with A-No. 8 or F-No. 43 filler metal in base material of: 1½ in. or less over 1½ in. to 3 in. over 3 in.	...	0.30	100
		...	0.30	200
		...	0.30	250
				[Note (4)] [Note (5)]

NOTES:

- (1) The exemptions noted in this Table do not apply to electron beam welds in ferritic materials over ¼ in. in thickness.
- (2) This exemption is limited to SA-299, SA-516, SA-537, and SA-738 materials, under the following conditions:
 - (a) The exemption from impact testing as provided in NE-2311(a)(8) is not permitted.
 - (b) For Charpy V Notch Testing per NE-2331(a)(1), the testing criteria are as described in either of the following:
 - (1) The testing temperature is 10°F below the Lowest Service Metal Temperature, and the C_v energy values are as shown in Table NE-2332.1-2.
 - (2) The testing temperature is the Lowest Service Metal Temperature, and the C_v energy values are increased by 5 ft.-lb. over those shown in Table NE-2332.1-2.
 - (c) For Drop Weight Testing permitted by NE-2331(a)(2), the difference between Lowest Service Metal Temperature and the nil ductility transition temperature, (LSMT - T_{NDT}), is equal to or greater than (10°F + A), in which the value of A is determined in accordance with Appendix R.
- (3) Maximum process heat input = 150,000 J/in. The maximum resulting hardness of the heat affected zone in the procedure qualification test plate shall not exceed 35 Rc.
- (4) Intermediate postweld soak at not less than 200°F for 2 hr minimum.
- (5) Intermediate postweld soak at not less than 300°F for 2 hr minimum.
- (6) Where the thickness of material is identified in the Type of Weld column, it is the thickness of the base material at the welded joint.
- (7) Carbon level of the pressure retaining materials being joined.

[98]

TABLE NE-4622.7(b)-1 EXEMPTIONS TO MANDATORY PWHT¹

(c) welds subjected to temperatures above the PWHT temperature range specified in Table NE-4622.1-1, provided the Welding Procedure Specification is qualified in accordance with Section IX and the base material and the deposited weld material have been heat treated at the higher temperature;

(d) extensions and the welds joining these extensions to nozzles, opening frames, and similar construction, provided all other requirements of NE-4620 are met and the weld is located at least $0.5\sqrt{rt}$ from the surface of the vessel, where r is the mean radius of the nozzle or opening and t is the nominal thickness of the nozzle or opening;

(e) nonpressure parts attached to pressure parts which have been previously postweld heat treated, provided the attachment welds meet the requirements of Table NE-4622.7(b)-1.

NE-4623 PWHT Heating and Cooling Rate Requirements

Above 800°F (427°C) the rate of heating and cooling in any hourly interval shall not exceed 400°F (222°C) divided by the maximum thickness in inches of the material being heat treated, but shall not exceed 400°F (222°C) and need not be less than 100°F (56°C) in any hourly interval. During the heating and cooling period there shall not be a greater variation in temperature than 250°F (139°C) within any 15 ft (4.6 m) interval of weld length.

NE-4624 Methods of Postweld Heat Treatment

The postweld heat treatment shall be performed in accordance with the requirements of one of the following subparagraphs.

NE-4624.1 Furnace Heating - One Heat.

Heating the vessel or item in a closed furnace in one heat is the preferred procedure and should be used whenever practical. The furnace atmosphere shall be controlled so as to avoid excessive oxidation, and direct impingement of flame on the vessel or item is prohibited.

NE-4624.2 Furnace Heating - More Than One Heat.

The vessel or item may be heated in more than one heat in a furnace, provided the furnace atmosphere control requirements of NE-4624.1 apply and overlap of the heated sections of the vessel or item is at least 5 ft. When this procedure is used, the portion of the vessel or item outside the furnace shall be shielded so that the temperature gradient is not harmful. The cross section where the vessel or item projects from the furnace shall not intersect a nozzle or other structural discontinuity.

NE-4624.3 Local Heating.

Welds may be locally postweld heat treated when it is not practical to heat treat the entire vessel or item. Local postweld heat treatment shall consist of heating a circumferential band around the vessel or item at temperatures within the ranges specified in this Subarticle. The minimum width of the controlled band at each side of the weld, on the face of the greatest weld width, shall be the thickness of the weld or 2 in. (51 mm), whichever is less. The temperature of the vessel or item from the edge of the controlled band outward shall be gradually diminished so as to avoid harmful thermal gradients. This procedure may also be used for postweld heat treatment after repairs.

NE-4624.4 Heating Vessels Internally.

The vessel or item may be heated internally by any appropriate means and with adequate indicating and recording temperature devices to aid in the control and maintenance of a uniform distribution of temperature in the vessel or item. Prior to this operation, the vessel or item shall be fully enclosed with insulating material.

NE-4630 INTERMEDIATE POSTWELD HEAT TREATMENT

The temperature, time-at-temperature, and heating and cooling rate requirements of NE-4620 are not mandatory for

intermediate heat treatments.

NE-4660 HEAT TREATMENT OF ELECTROSLAG WELDS

Electroslag welds in ferritic material over $1\frac{1}{2}$ in. (38 mm) in thickness at the joints shall be given a grain refining heat treatment.

NE-4700 MECHANICAL JOINTS AND PENETRATION ASSEMBLIES

NE-4710 BOLTING AND THREADING

NE-4711 Thread Engagement

The threads of all bolts or studs shall be engaged in accordance with the design.

Page 149

NE-4712 Thread Lubricants

Any lubricant or compound used in threaded joints shall be suitable for the service conditions and shall not react unfavorably with either the service fluid or any material in the system.

NE-4713 Removal of Thread Lubricants

All threading lubricants or compounds shall be removed from surfaces which are to be seal welded.

NE-4714 Stud Threading

Studs shall be threaded full length or shall be machined down to the root diameter of the thread in the unthreaded portion.

NE-4720 BOLTING FLANGED JOINTS

In bolting gasketed flanged joints, the contact faces of the flanges shall bear uniformly on the gasket and the gasket shall be properly compressed in accordance with the design principles applicable to the type of gasket used. All flanged joints shall be made up with relatively uniform bolt stress.

NE-4730 ELECTRICAL AND MECHANICAL PENETRATION ASSEMBLIES

(a) Electrical and mechanical penetration assemblies, except for those portions performing an electrical conducting or insulating function, shall be constructed in accordance with the rules for containment vessels.

(b) Tubes or pipe of NPS 2 (DN 50) and less may be joined to a penetration assembly in accordance with the rules of NE-4740.

(c) The closing seam for the penetration assembly may be made with a multipass single lap fillet weld as shown in Fig.2 NE-4730-1, provided the requirements of (1) through (5) below are met:

(1) one of the heads on the penetration assembly meets the requirements of NE-3352.1;

(2) the penetration assembly shall not exceed 18 in. O.D;

(3) the design pressure of the penetration assembly shall not exceed 100 psi (690 kPa) and the design temperature shall not exceed 400°F (204°C);

(4) examination of the fillet weld shall be by the liquid penetrant method in accordance with NE-5350;

(5) the fillet weld and closure head shall meet the requirements of NE-3720(b).

FIG. NE-4730-1 PENETRATION ASSEMBLY

FIG. NE-4730-1 PENETRATION ASSEMBLY

NE-4740 SPECIAL QUALIFICATION REQUIREMENTS FOR ELECTRICAL AND MECHANICAL PENETRATION ASSEMBLIES

NE-4741 General Requirements

These rules are applicable only for the attachment of pipes and tubes of NPS 2 (DN 50) and less to electrical and mechanical penetration assemblies as permitted in NE-4730. The welding procedure shall be qualified as a new procedure specification and shall be completely requalified when any of the changes listed below are made in the procedure. Changes other than those so given may be made in a procedure without the necessity for requalification, provided the procedure specification is amended to show these changes.

NE-4742 Essential Variables for All Welding Processes

Essential variables for all welding processes shall be as listed in (a) through (k) below:

- (a) a change from one welding process to any other welding process or combination of welding processes;
- (b) a change in the P-Number classification of pipe or tube material in Section IX, QW-442 and QW-422; a separate qualification is required for each pipe or tube material which is not included under any P-Number;
- (c) a change in the P-Number of the penetration assembly;

Page 150

(l) the base material may be a homogeneous material or a cladding material of wrought-type or weld-overlay-type; if welding is performed between the pipe or tube and cladding, the cladding shall be considered the base material; a separate qualification is required for welding pipes or tubes to base material or cladding material which is not included under any P-Number;

(d) changes in the weld metal analysis of the deposited weld metal as given in (1) and (2) below:

(1) a change from any A-Number in Section IX, QW-442, to any other A-Number or to any F-Number in QW-432 or to any analysis not listed in the tables, except that each AISI type similar to A-No. 7 or A-No. 8 of QW-442 shall require separate qualifications;

(2) a change from any F-Number in QW-432 to any other F-Number or to any A-Number in QW-442 or to any analysis not listed in the tables;

(e) for pipes or tubes of specified wall thickness of 0.100 in. or less, an increase or decrease of 10% of specified wall thickness or specified diameter;

(f) for specified wall thicknesses greater than 0.100 in. (2.54 mm), only one qualification test is required;

(g) a decrease of 10% or more in the specified width of the ligament between holes when the specified width of the ligament is less than the greater of $\frac{3}{8}$ in. (10 mm) or three times the specified pipe or tube wall thickness;

(h) the addition of other welding positions than those already qualified (Section IX, QW-461.1);

(i) a change in the specified preheating temperature range;

(j) a change in the specified postweld heat treating temperature;

(k) a change from multiple pass to single pass or vice versa.

NE-4743 Essential Variables for Shielded Metal-Arc Welding

Additional essential variables for shielded metal-arc welding are as given in (a) and (b) below:

(a) an increase in electrode diameter;

(b) a change from one F-Number in Section IX, QW-422 or QW-432, to any other F-Number (Notes 2 and 3 in QW-432 shall apply).

NE-4744 Essential Variables for Gas Tungsten-Arc and Gas Metal-Arc Welding

Additional essential variables for gas tungsten-arc and gas metal-arc welding are as given in (a) through (f) below:

(a) a change in the configuration of the penetration assembly at the hole edges, including the addition or omission of preplaced metal inserts;

(b) a change in the size or shape of preplaced metal inserts;

(c) a change from one shielding gas to another shielding gas or to a mixture of shielding gases;

(d) when using mixed shielding gas, a change of $\pm 25\%$ or 5 cu ft/hr (0.14 m³/hr), whichever is the larger, in the rate of flow of the minor gas constituent;

- (e) for gas tungsten-arc welding process, the addition or omission of filler metal;
- (f) a change in the nominal diameter of the filler metal.

NE-4745 Test Assembly

The procedure qualification shall be made on a test assembly which simulates the conditions to be used in production with respect to the hole pattern and the essential variables listed in NE-4741. In addition, the thickness of the test assembly at the holes shall be as thick as the production penetration assembly at the holes, except that it need not exceed 2 in. (51 mm). The minimum required number of weld joints shall be ten.

NE-4746 Examination of Test Assembly

The test assembly shall be examined by a liquid penetrant method in accordance with the requirements of NE-5110 and shall meet the acceptance standards of NE-5350. Following this, the test assembly shall be sectioned longitudinally through each pipe or tube. The thickness of the test assembly may be reduced to $\frac{1}{2}$ in. (13 mm) prior to this sectioning. The four faces of each pipe or tube exposed by sectioning shall be polished and etched with a suitable etchant and shall be visually examined for cracks. The weld throat, minimum leakage path, shall be not less than two-thirds of the specified pipe or tube wall thickness, and the weld shall be free from cracks on visual examination with $\times 10$ magnification.

NE-4747 Performance Qualification Test

The requirements for the performance qualification test for welders and welding operators shall be the same as those for the procedure qualification, except that the minimum required number of tubes in the test assembly shall be six. Any welder or welding operator who makes a procedure test that passes satisfactorily is thereby qualified.

Page 151

NE-4800 EXPANSION JOINTS

NE-4810 BELLOWS-TYPE EXPANSION JOINTS

For bellows-type expansion joints the requirements of (a) through (e) below shall be met.

- (a) All welded joints shall comply with the requirements of NE-4400.
- (b) The longitudinal weld in the bellows shall be a butt-type full penetration weld.
- (c) The bellows element of the expansion joint shall be attached to the welding ends or flange by circumferential welds of a butt-type having full penetration weld through the thickness of the bellows portion, as shown in Fig. NE-4810(c)-1.
- (d) Other than the attachment welds, no circumferential welds are permitted in the bellows elements.
- (e) Weld repairs shall not be permitted on parent material of bellows elements.

FIG. NE-4810(c)-1 BELLOWS ATTACHMENT WELDS

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NE-5000

ARTICLE NE-5000 EXAMINATION

Page 153

NE-5100 GENERAL REQUIREMENTS FOR EXAMINATION OF VESSELS

NE-5110 PROCEDURES, QUALIFICATIONS, AND EVALUATION

NE-5111 General Requirements

Nondestructive examinations shall be conducted in accordance with the examination methods of Section V, except as they may be modified by the requirements of this Article. Radiographic examination shall be in accordance with Section V, Article 2, except that the geometric unsharpness shall not exceed the limits of T-285. Ultrasonic examination shall be in accordance with Section V, Article 5; magnetic particle examination shall be in accordance with Section V, Article 7; and liquid penetrant examination shall be in accordance with Section V, Article 6. The examinations required by this Article or by reference to this Article shall be performed by personnel who have been qualified as required by this Article. The results of the examinations shall be evaluated in accordance with the acceptance standards of this Article.

NE-5112 Nondestructive Examination Procedures

All nondestructive examinations required by this Article shall be performed in accordance with detailed written procedures which have been proven by actual demonstration to the satisfaction of the Inspector. The procedures shall comply with the appropriate Article of Section V for the particular examination method. The digitization of radiographic film and radiosopic images shall meet the requirements of Section V, Article 2, Mandatory Appendix III, "Digital Image Acquisition, Display, and Storage for Radiography and Radioscopy." Written procedures and records of demonstration of procedure capability and personnel qualification shall be made available to the Inspector on request. At least one copy of the procedure shall be readily available to all applicable nondestructive examination personnel for reference and use.

NE-5113 Post-Examination Cleaning

Following any nondestructive examination in which examination materials are applied to the piece, the piece shall be thoroughly cleaned in accordance with applicable material or procedure specifications.

NE-5120 TIME OF EXAMINATION OF WELDS

Acceptance examination of welds required by NE-5200 shall be performed at the times stipulated in (a), (b), and (c) below.

(a) Radiographic examination of all welds in vessels may be performed prior to any required postweld heat treatment.

(b) Magnetic particle or liquid penetrant examinations shall be performed after any required postweld heat treatment, except that welds in P-No. 1 material may be examined either before or after postweld heat treatment.

(c) All dissimilar metal weld joints, such as in austenitic or high nickel to ferritic material or using austenitic or high nickel alloy filler metal to join ferritic materials, which penetrate the vessel wall shall be examined after final postweld heat treatment.

(d) Ultrasonic examination of electroslog welds in ferritic materials shall be performed after a grain refining heat treatment, when performed, or after final postweld heat treatment.

NE-5130 EXAMINATION OF WELD EDGE PREPARATION SURFACES

All full penetration weld edge preparation surfaces for joint Categories A, B, C, D, and similar joints in material 2 in. or more in thickness shall be examined

Page 156

by the magnetic particle or liquid penetrant method. Indications shall be evaluated in accordance with the acceptance standards of (a), (b), and (c) below.

(a) Only indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Laminar-type imperfections are acceptable without repair if they do not exceed 1 in. (25 mm) in length. The extent of all laminar-type imperfections exceeding 1 in. (25 mm) in length shall be determined by ultrasonic examination. Imperfections exceeding 1 in. (25 mm) in length shall be repaired by welding to a depth of $\frac{3}{8}$ in. (10 mm) or the depth of the imperfection, whichever is less, unless the ultrasonic examination reveals that additional depth of repair is required to meet the ultrasonic examination requirement for the product form.

(c) Indications of nonlaminar imperfections of (1) through (3) below are unacceptable:

(1) any linear indications greater than $\frac{3}{16}$ in. (4.8 mm) long;

(2) rounded indications with dimensions greater than $\frac{3}{16}$ in. (4.8 mm);

(3) four or more indications, in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less, edge to edge.

(d) Weld repairs made to weld edge preparations for Category A, B, C, D, or similar type welds shall be examined by the magnetic particle or liquid penetrant method before the surfaces become inaccessible. The examination may be performed before or after postweld heat treatment.

NE-5200 REQUIRED EXAMINATION OF WELDS

NE-5210 CATEGORY A WELDED JOINTS

NE-5211 Butt Welded Joints

Category A welded joints shall be fully radiographed.

NE-5220 CATEGORY B WELDED JOINTS

[98]

NE-5221 Butt Welds

Circumferential welds as defined in NE-3351.2 shall be radiographed. The provision of NE-5280 is applicable.

[98]

NE-5230 CATEGORY C WELDED JOINTS

NE-5231 Butt Welds

Category C butt welds shall be radiographed.

NE-5232 Nonbutt-Welded Joints

(a) If other than a butt welded joint detail is used, it shall be examined by the ultrasonic method, magnetic particle method, or liquid penetrant method.

(b) When a pressure retaining part is to be welded to a plate thicker than $\frac{1}{2}$ in. (13 mm) to form a corner joint as shown in Fig. NE-4243-1 and Fig. NE-4243-2 sketches (a), (b), and (c), the plate shall be examined before welding on all cut edges adjacent to the weld, including those for weld joint preparation, by magnetic particle or liquid penetrant examination. After welding, all such edges that remain exposed shall be reexamined. Where the material is nonmagnetic, only the liquid penetrant method shall be used.

NE-5240 CATEGORY D WELDED JOINTS

NE-5241 Butt Welds

Category D butt welds shall be radiographed.

NE-5242 Nonbutt-Welded Joints

If other than a butt welded joint detail is used, it shall be examined by an ultrasonic method, a magnetic particle method, or a liquid penetrant method. Welds on reinforcing plates attached to the outside of the vessel shall be solution film tested with a pressure of at least 15 psi (103 kPa) under the reinforcing plate.

NE-5244 Weld Buildup Deposits for Openings and Nozzles

When weld buildup deposits are made to a surface as shown in Step 1 of Fig. NE-4244(c)-1, the weld buildup deposit, the fusion zone, and the parent metal beneath the weld buildup deposit shall be ultrasonically examined to assure freedom from lack of fusion and laminar defects. Opening structures or nozzles may then be attached by a full penetration weld as shown in Step 2 of Fig. NE-4244(c)-1. The full penetration weld shall be examined in accordance with NE-5241.

Page 157

NE-5260 ATTACHMENTS

NE-5261 Butt Welded Joints

All butt welded joints in pressure retaining parts not included in Categories A, B, C, and D, such as those on doors, opening frames, permanent attachments, and similar construction, shall be radiographed. Butt welds in nonpressure-retaining structural parts attached to pressure retaining parts shall be fully radiographed for a minimum distance of $16t$, where t is the thickness of the structural part.

NE-5262 Nonbutt-Welded Joints

If other than a butt welded joint detail is used on pressure retaining parts, it shall be examined by an ultrasonic method, a magnetic particle method, or a liquid penetrant method, all in accordance with NE-5110. For nonpressure-retaining structural parts attached to pressure retaining parts in which nonbutt-welds are used, the portion of the attachment within

the limit of $16t$ shall be examined in the same manner.

NE-5270 SPECIAL WELDS

Weld metal cladding shall be examined by the liquid penetrant method.

NE-5278 Electroslag Welds

In addition to the requirements for the type of weld being examined, all complete penetration welds made by the electroslag welding process in ferritic materials shall be ultrasonically examined.

[98]

NE-5280 SPECIAL EXCEPTIONS FOR RADIOGRAPHY

(a) When the joint detail does not permit radiographic examination, ultrasonic examination plus liquid penetrant or magnetic particle examination of the completed weld may be substituted for:

- (1) joints attaching penetration assemblies, which are fabricated as appurtenances to a vessel;
- (2) the closing seam within an electrical penetration assembly, not necessarily fabricated as an appurtenance; or
- (3) the closing seam in a piping assembly which performs a containment function and which provides for the process piping to penetrate the containment vessel.

(b) The absence of suitable radiographic equipment shall not be justification for such a substitution. The substitution of ultrasonic examination can be made, provided the examination is performed using a detailed written procedure which has been proved by actual demonstration to the satisfaction of the Authorized Inspector as being capable of detecting and locating continuities. The nondestructive examination shall be in accordance with NE-5110 and shall meet the acceptance standards of NE-5330 for the ultrasonic examination, NE-5340 for the magnetic particle examination, and NE-5350 for the liquid penetrant examination.

[98]

NE-5300 ACCEPTANCE STANDARDS

NE-5320 RADIOGRAPHIC ACCEPTANCE STANDARDS

Indications shown on the radiographs of welds and characterized as imperfections are unacceptable under the following conditions:

- (a) any indication characterized as a crack or zone of incomplete fusion or penetration;
- (b) any other elongated indication which has a length greater than:
 - (1) $\frac{1}{4}$ in. for t up to $\frac{3}{4}$ in., inclusive
 - (2) $\frac{1}{3}t$ for t from $\frac{3}{4}$ in. to $2\frac{1}{4}$ in., inclusive
 - (3) $\frac{3}{4}$ in. for t over $2\frac{1}{4}$ in.

where t is the thickness of the thinner portion of the weld;

(c) internal root weld conditions are acceptable when the density change as indicated in the radiograph is not abrupt; elongated indications on the radiograph at either edge of such conditions shall be unacceptable, as provided in (b) above;

(d) any group of aligned indications having an aggregate length greater than t in a length of $12t$ unless the minimum distance between successive indications exceeds $6L$, in which case the aggregate length is unlimited, L being the length of the largest indication;

(e) rounded indications in excess of that shown as acceptable in Appendix VI.

NE-5330 ULTRASONIC ACCEPTANCE STANDARDS

All imperfections which produce a response greater than 20% of the reference level shall be investigated to the extent that the operator can determine the shape, identity, and location of all such imperfections and evaluate them in terms of the acceptance standards as given in (a) and (b) below.

Page 158

(a) Imperfections are unacceptable if the indications exceed the reference level amplitude and have lengths exceeding:

- (1) $\frac{1}{4}$ in. for t up to $\frac{3}{4}$ in., inclusive
- (2) $\frac{1}{3}t$ for t from $\frac{3}{4}$ in. to $2\frac{1}{4}$ in., inclusive
- (3) $\frac{3}{4}$ in. for t over $2\frac{1}{4}$ in.

where t is the thickness of the weld being examined; if a weld joins two members having different thicknesses at the weld, t is the thinner of these two thicknesses.

(b) Indications characterized as cracks, lack of fusion, or incomplete penetration are unacceptable regardless of length.

NE-5340 MAGNETIC PARTICLE ACCEPTANCE STANDARDS

NE-5341 Evaluation of Indications

(a) Mechanical discontinuities at the surface are revealed by the retention of the examination medium. All indications are not necessarily defects, however, since certain metallurgical discontinuities and magnetic permeability variations may produce similar indications which are not relevant.

(b) Any indication which is believed to be nonrelevant shall be reexamined by the same or other nondestructive examination methods to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. After an indication has been verified to be nonrelevant, it is not necessary to reinvestigate repetitive nonrelevant indications of the same type. Nonrelevant indications which would mask defects are unacceptable.

(c) Relevant indications are indications which result from imperfections. Linear indications are indications in which the length is more than three times the width. Rounded indications are indications which are circular or elliptical with the length equal to or less than three times the width.

NE-5342 Acceptance Standards

(a) Only imperfections producing indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Imperfections producing the following indications are unacceptable:

- (1) any cracks or linear indications;
- (2) rounded indications with dimensions greater than $\frac{3}{16}$ in. (4.8 mm);
- (3) four or more rounded indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;
- (4) ten or more rounded indications in any 6 sq in. (3871 mm²) of surface with the major dimension of this area not to exceed 6 in. (152 mm) with the area taken in the most unfavorable location relative to the indications being evaluated.

NE-5350 LIQUID PENETRANT ACCEPTANCE STANDARDS

NE-5351 Evaluation of Indications

(a) Mechanical discontinuities at the surface are revealed by bleeding out of the penetrant; however, localized surface discontinuities such as may occur from machining marks or surface conditions may produce similar indications which are nonrelevant.

(b) Any indication which is believed to be nonrelevant shall be reexamined to verify whether or not actual defects are

present. Surface conditioning may precede the reexamination. Nonrelevant indications and broad areas of pigmentation which would mask defects are unacceptable.

(c) Relevant indications are indications which result from imperfections. Linear indications are indications in which the length is more than three times the width. Rounded indications are indications which are circular or elliptical with the length equal to or less than three times the width.

NE-5352 Acceptance Standards

(a) Only imperfections producing indications with major dimensions greater than $\frac{1}{16}$ in. (1.6 mm) shall be considered relevant imperfections.

(b) Imperfections producing the following indications are unacceptable:

(1) any cracks or linear indications;

(2) rounded indications with dimensions greater than $\frac{3}{16}$ in. (4.8 mm);

(3) four or more rounded indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;

(4) ten or more rounded indications in any 6 sq in. (3871 mm²) of surface with the major dimension of this area not to exceed 6 in. (152 mm) with the area taken in the most unfavorable location relative to the indications being evaluated.

Page 159

NE-5500 QUALIFICATIONS AND CERTIFICATION OF NONDESTRUCTIVE EXAMINATION PERSONNEL

NE-5510 GENERAL REQUIREMENTS

Organizations performing Code required nondestructive examinations shall use personnel competent and knowledgeable to the degree specified by NE-5520. When these services are subcontracted by the Certificate Holder or Quality System Certificate Holder, he shall verify the qualification of personnel to the requirements of NE-5520. All nondestructive examinations required by this Subsection shall be performed by and the results evaluated by qualified nondestructive examination personnel.

NE-5520 PERSONNEL QUALIFICATION, CERTIFICATION, AND VERIFICATION

NE-5521 Qualification Procedure

(a) Personnel performing nondestructive examinations shall be qualified in accordance with the recommended guidelines of SNT-TC-1A.^{1,2} The Employer's³ written practice required by paragraph 5 of SNT-TC-1A shall identify his requirements relative to the recommended guidelines. The recommended guidelines of SNT-TC-1A shall be considered minimum requirements, except as modified in (1) through (5) below.

(1) Qualification of Level III nondestructive examination personnel shall be by examination.

(a) The basic and method examinations, paragraphs 8.8(1) and 8.8(2) of SNT-TC-1A, may be prepared and administered by the Employer, ASNT, or an outside agency.

1 SNT-TC-1A is a Recommended Practice for Nondestructive Testing Personnel Qualification and Certification published by the American Society for Nondestructive Testing, 1711 Arlingate Lane, P.O. Box 28518, Columbus, Ohio 43228-0518. SNT-TC-1A-1992 is the applicable edition.

2 Personnel qualified by examination and certified to previous editions of SNT-TC-1A are considered to be qualified to the 1992 edition when the recertification is based on continuing satisfactory performance. All reexaminations and new examinations shall be in accordance with the 1992 edition.

3 Employer as used in this Article shall include: N Certificate Holders; Quality System Certificate Holders; Material Organizations who are qualified in accordance with NCA-3862(a)(1); and organizations who provide subcontracted nondestructive examination services to organizations described above.

(b) The specific examination, paragraph 8.8(3) of SNT-TC-1A, shall be prepared and administered by the Employer or an outside agency. The Employer or outside agency administering the specific examination shall identify the

minimum grade requirement in the written program when the basic and method examinations have been administered by ASNT, which issues grades on a pass/fail basis. In this case, the minimum grade for the specific examination may not be less than 80%.

(2) The written practice identified in paragraph 5 of SNT-TC-1A and the procedures used for examination of personnel shall be referenced in the Employer's Quality Program.

(3) The number of hours of training and experience for nondestructive examination personnel who perform only one operation of a nondestructive examination method that consists of more than one operation, or perform nondestructive examination of limited scope, may be less than that recommended in Table 6.3.1 of SNT-TC-1A. The training and experience times shall be described in the written practice, and any limitations or restrictions placed on the certification shall be described in the written practice and on the certificate.

(a) The minimum classroom training times identified in Table 6.3.1 of SNT-TC-1A may be reduced from 8 and 16 hr to 4 and 8 hr respectively for visual examination personnel.

(4) For visual examination, the Jaeger Number 1 letters shall be used in lieu of the Jaeger Number 2 letters specified in paragraph 8.2(1) of SNT-TC-1A. The use of equivalent type and size letters is permitted.

(5) A Level I individual shall be qualified to perform specific setups, calibrations, and tests, and to record and evaluate data by comparison with specific acceptance criteria defined in written instructions. The Level I individual shall implement these written NDE instructions under the guidance of a Level II or III individual. A Level I individual may independently accept the results of nondestructive examinations when the specific acceptance criteria are defined in the written instructions.

(b) For nondestructive examination methods not covered by SNT-TC-1A documents, personnel shall be qualified to comparable levels of competency by subjection to comparable examinations on the particular method involved.

(c) The emphasis shall be on the individual's ability to perform the nondestructive examination in accordance with the applicable procedure for the intended application.

(d) For nondestructive examination methods that consist of more than one operation or type, it is permissible to use personnel qualified to perform one or more operations. As an example, one person may be used who is qualified to conduct radiographic examination and another may be used who is qualified to interpret and evaluate the radiographic film.

Page 160

NE-5522 Certification of Personnel

(a) The Employer retains responsibility for the adequacy of the program and is responsible for certification of Levels I, II, and III nondestructive examination personnel.

(b) When ASNT is the outside agency administering the Level III basic and method examinations [NE-5521(a)(2)], the Employer may use a letter from ASNT as evidence on which to base the certification.

(c) When an outside agency is the examining agent for Level III qualification of the Employer's personnel, the examination results shall be included with the Employer's record.

NE-5523 Verification of Nondestructive Examination Personnel Certification

The Certificate Holder has the responsibility to verify the qualification and certification of nondestructive examination personnel employed by Material Organizations qualified by them in accordance with NCA-3820 and subcontractors who provide nondestructive examination services to them.

NE-5530 RECORDS

Personnel qualification records identified in paragraph 9.4 of SNT-TC-1A shall be retained by the Employer.

NE-5700 EXAMINATION REQUIREMENTS FOR EXPANSION JOINTS

NE-5710 BELLOWS EXPANSION JOINTS

The examinations stipulated in (a) through (f) below are required to verify the integrity of bellows expansion joints for installation in nuclear containment systems.

(a) The formed bellows shall be determined by visual examination to be free of defects, such as notches, crevices, material buildup or upsetting, and weld spatter which may serve as points of local stress concentration. Suspect surface areas shall be further examined by liquid penetrant examination in accordance with NE-5110.

(b) The longitudinal welds in the bellows shall be examined by the liquid penetrant method in accordance with NE-5111. When the individual ply thickness exceeds $\frac{1}{8}$ in. (3.2 mm), the weld shall also be radiographed in accordance with NE-5111. These examinations may be performed either before or after the bellows is formed.

(c) The circumferential attachment weld between the bellows and weld ends or flanges shall be liquid penetrant examined in accordance with NE-5110 when the total bellows thickness is $\frac{1}{4}$ in. (6 mm) or less. When the total thickness exceeds this limit, the weld shall be radiographed in accordance with NE-5110 except where radiography is not meaningful, i.e., when the weld thickness constitutes less than 20% of the total thickness being radiographed, liquid penetrant examination may be substituted.

(d) In the case of liquid penetrant examination of bellows weld joints, imperfections producing the following indications are unacceptable:

- (1) cracks or linear indications;
- (2) four or more rounded indications in a line separated by $\frac{1}{16}$ in. (1.6 mm) or less edge to edge;
- (3) five or more randomly distributed rounded indications in a weld length of 6 in. (152 mm);
- (4) any rounded indication exceeding the lesser of one-half the bellows thickness or $\frac{1}{16}$ in. (1.6 mm) in diameter.

(e) The examination of all other welds in the expansion joint shall comply with NE-5000.

(f) The variation of the cylindrical end thickness of the formed bellows from the nominal or specified thickness shall not exceed the values given in Table 2 of SA-480. Thinning of the bellows material during forming shall be considered in the design and selection of material thickness but need not be limited to values specified in Table 2 of SA-480.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NE-6000

ARTICLE NE-6000 TESTING

Page 161

NE-6100 GENERAL REQUIREMENTS

NE-6110 PRESSURE TESTING OF VESSELS AND APPURTENANCES

NE-6111 Scope of Pressure Testing

All pressure retaining vessels and appurtenances (hereafter reference is to vessels only) shall be pressure tested. Bolts, studs, nuts, washers, and gaskets are exempted from the pressure test.

NE-6112 Pneumatic Testing

A pneumatic test in accordance with NE-6300 may be substituted for the hydrostatic test when permitted by NE-6112.1 (a).

NE-6112.1 Pneumatic Test Limitations

(a) A pneumatic test may be used in lieu of a hydrostatic test only when any of the following conditions exists:

(1) when the vessels are so designed or supported that they cannot be safely filled with liquid;¹

(2) when the vessels, which are not readily dried, are to be used in services where traces of the testing medium cannot be tolerated.

(b) A pneumatic test at a pressure not to exceed 10% of the test pressure may be applied prior to either a hydrostatic or a pneumatic test as a means of locating leaks.

NE-6112.2 Precautions to Be Employed in Pneumatic Testing.

Compressed gaseous fluid is hazardous when used as a testing medium. It is therefore recommended that special precautions for protection of personnel be taken when a gaseous fluid under pressure is used as a test medium.

1 These tests may be made with the item being tested partially filled with liquid, if desired.

NE-6113 Witnessing of Pressure Tests

Pressure testing required by this Article shall be performed in the presence of the Inspector.

NE-6120 PREPARATION FOR TESTING

NE-6121 Exposure of Joints

All joints, including welded joints, shall be left uninsulated and exposed for examination during the test, except as permitted in NE-6225.

NE-6122 Addition of Temporary Supports

Vessels designed to contain vapor or gas may be provided with additional temporary supports, if necessary, to support the weight of the test liquid.

NE-6123 Restraint or Isolation of Expansion Joints

Expansion joints shall be provided with temporary restraints, if required, for the additional pressure load under test.

NE-6124 Isolation of Equipment Not Subjected to Pressure Test

Equipment that is not to be subjected to the pressure test shall be either disconnected from the vessel or isolated during the test by a blind flange or similar means. Valves may be used if the valves with their closures are suitable for the proposed test pressure.

NE-6125 Treatment of Flanged Joints Containing Blanks

Flanged joints at which blanks are inserted to isolate other equipment during the test need not be retested.

Page 164

NE-6126 Precautions Against Test Medium Expansion

If a pressure test is to be maintained for a period of time and the test medium in the system is subject to thermal expansion, precautions shall be taken to avoid excessive pressure.

NE-6127 Check of Test Equipment Before Applying Pressure

The test equipment shall be examined before pressure is applied to ensure that it is tight and that all low pressure filling lines and other items that should not be subjected to the test have been disconnected or isolated.

NE-6200 HYDROSTATIC TESTS

NE-6210 HYDROSTATIC TEST PROCEDURE

NE-6211 Venting During Fill Operation

The vessel in which the test is to be conducted shall be vented during the filling operation to minimize air pocketing.

NE-6212 Test Medium and Test Temperature

(a) Water or an alternative liquid, as permitted by the Design Specification, shall be used for the hydrostatic test.

(b) It is recommended that the test be made at a temperature that will minimize the possibility of brittle fracture. The test pressure shall not be applied until the vessel and the pressurizing fluid are at approximately the same temperature.

NE-6220 HYDROSTATIC TEST PRESSURE REQUIREMENTS

NE-6221 Minimum Hydrostatic Test Pressure

The vessel shall be hydrostatically tested at not less than 1.35 times the Design Pressure.

NE-6222 Maximum Permissible Test Pressure

The stress limits specified in NE-3226 shall be used in determining the maximum permissible test pressure. In multichamber components, pressure may be simultaneously applied to the appropriate adjacent chamber to satisfy these stress limits.

NE-6223 Hydrostatic Test Pressure Holding Time

The hydrostatic test pressure shall be maintained a minimum of 10 min prior to initiation of the examination for leakage required by NE-6224.

NE-6224 Examination for Leakage After Application of Pressure

Following the application of the hydrostatic test pressure for the required time (NE-6223), all joints, connections, and regions of high stress, such as regions around openings and thickness transition sections, shall be examined for leakage, except as provided in NE-6225. This examination shall be made at a pressure equal to the greater of the Design Pressure or three-fourths of the test pressure, and it shall be witnessed by the Inspector. Leakage of temporary gaskets and seals, installed for the purpose of conducting the hydrostatic test and which will be replaced later, may be permitted unless the leakage exceeds the capacity to maintain system test pressure for the required amount of time. Other leaks, such as those from permanent seals, seats, and gasketed joints in components, may be permitted when specifically allowed by the Design Specification. Leakage from temporary seals or leakage permitted by the Design Specification shall be directed away from the surface of the component to avoid masking leaks from other joints.

NE-6225 Examination of Inaccessible Welds

Examination of inaccessible pressure retaining welds of containment vessels during the pressure test is waived where such joints are covered by concrete or otherwise made inaccessible during construction of the vessel, provided that:

(a) no openings or penetrations are embedded in the concrete;

(b) the nozzle is integrally reinforced and is attached to the shell by a full penetration weld;

(c) prior to being covered or made inaccessible, the welds are examined by the radiographic or ultrasonic method;

(d) prior to being covered or made inaccessible, the welded joint is tested for leak tightness using a gas medium test such as the Halide Leak Detection Test or Vacuum Box Test.

NE-6230 BELLOWS EXPANSION JOINTS

The hydrostatic test requirements for bellows expansion joints shall be as required in (a) through (c) below.

(a) The completed expansion joint shall be subjected to a hydrostatic test in accordance with the applicable provisions of this Article as supplemented by the Design Specification.

(b) This test may be performed with the bellows fixed in the straight position, at its neutral length, when the design has been shown to comply with NE-3365.2(e)(1) or NE-3365.2(e)(2). If the design is to comply with NE-3365.2(e)(3), this test shall be performed with the bellows fixed at the maximum design rotation angle or offset movement.

(c) In addition to inspecting the expansion joint for leaks and general structural integrity during the test, the Inspector shall also visually inspect the bellows for evidence of meridional yielding as defined in NE-3365.2(b), and for evidence of squirm as defined in NE-3365.2(c). If the design is to comply with NE-3365.2(e)(3), actual measurements shall be made before, during, and after the pressure test in accordance with NE-3365.2(b) and NE-3365.2(c).

NE-6300 PNEUMATIC TESTS

NE-6310 PNEUMATIC TESTING PROCEDURES

NE-6311 General Requirements

When a pneumatic test is performed, it shall be conducted in accordance with the requirements of this Subarticle and NE-6100. In some cases it is desirable to test vessels when partly filled with liquids. For such vessels, a combined hydrostatic and pneumatic test may be used as an alternative to the pneumatic test of this paragraph provided the liquid level is set so that the stress intensities of NE-3226 are not exceeded. After setting the liquid level to meet this condition, the test shall be conducted as prescribed in this Subarticle.

NE-6312 Test Medium and Test Temperature

(a) The gas used as the test medium shall be nonflammable.

(b) Testing temperature shall be in accordance with NE-6212(b).

NE-6313 Procedure for Applying Pressure

The pressure in the system shall be gradually increased to not more than one-half of the test pressure, after which the pressure shall be increased in steps of approximately one-tenth of the test pressure until the required test pressure has been reached.

NE-6320 PNEUMATIC TEST PRESSURE REQUIREMENTS

NE-6321 Minimum Required Pneumatic Test Pressure

The pneumatic test pressure for vessels shall not be less than 1.1 times the Design Pressure of the vessel.

NE-6322 Maximum Permissible Test Pressure

The maximum test pressure shall be limited as defined in NE-6222.

NE-6323 Test Pressure Holding Time

The test pressure of NE-6321 shall be maintained for a minimum total time of 10 min.

NE-6324 Examination for Leakage After Application of Pressure

Following the application of pressure for the time specified in NE-6323, the test pressure shall be reduced to a value equal to the greater of the Design Pressure or three-fourths of the test pressure and held for a sufficient time to permit

examination as defined in NE-6224.

NE-6400 PRESSURE TEST GAGES

NE-6410 REQUIREMENTS FOR PRESSURE TEST GAGES

NE-6411 Types of Gages to Be Used and Their Location

Pressure test gages used in pressure testing shall be indicating pressure gages and shall be connected directly to the vessel. If the indicating gage is not readily visible to the operator controlling the pressure applied, an additional indicating gage shall be provided where it will be visible to the operator for the duration of the test. For vessels with a large volumetric content,

Page 166

it is recommended that a recording gage be used in addition to the indicating gages.

NE-6412 Range of Indicating Pressure Gages

(a) Analog-type indicating pressure gages used in testing shall be graduated over a range not less than $1\frac{1}{2}$ times nor more than 4 times the test pressure.

(b) Digital-type pressure gages may be used without range restriction provided the combined error due to calibration and readability does not exceed 1% of the test pressure.

NE-6413 Calibration of Pressure Test Gages

All test gages shall be calibrated against a standard dead weight tester or a calibrated master gage. The test gages shall be calibrated before each test or series of tests. A series of tests is that group of tests using the same pressure test gage or gages which is conducted within a period not exceeding 2 weeks.

NE-6700 CONTAINMENT PENETRATION

NE-6710 PRESSURE TESTS

NE-6711 Electrical and Mechanical Penetration Assemblies

Electrical and mechanical penetration assemblies shall be tested in accordance with the requirements of this Article, except that when electrical and mechanical penetrations are made following the containment vessel pressure test, the test pressure of the welds connecting the electrical or mechanical penetration to the containment vessel may be less than the required containment test pressure but shall be not less than the design pressure of the containment vessel.

NE-6712 Piping Penetrations

Piping penetration assemblies shall be tested in accordance with the requirements of this Article, except that when piping penetrations are made following the containment vessel pressure test, the test pressure of the welds connecting the piping to the containment vessel may be less than the required containment test pressure but shall be not less than the design pressure of the containment vessel. The provisions of NB-6111 or NC-6111, as appropriate, apply to the process piping portion of the penetration assembly. The N-5 Data Report Form shall identify the test pressure used for each of the above pipe penetration weld connections.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NE-7000

ARTICLE NE-7000 OVERPRESSURE PROTECTION

Page 167

NE-7100 GENERAL REQUIREMENTS

NE-7110 SCOPE

(a) A containment vessel shall be protected from the consequence arising from the application of conditions of pressure and coincident temperature that would cause the Service or Test Limits specified in the Design Specification to be exceeded. Pressure relief or vacuum relief devices are not required where the Service or Test Limits specified in the Design Specification are not exceeded.

(b) Pressure relief devices not permanently installed in accordance with NE-7141 shall be removed from the containment vessel before placing the vessel in service.

(c) It is recognized that the fundamental purpose of a containment vessel may be nullified by the incorporation of pressure relief valves discharging directly into the environment. Vacuum relief devices or systems, including venting with controlled discharge or condensation systems, may be essential to protect against differential pressures in excess of design external pressures.

NE-7111 General Definitions

(a) *Overpressure*, as used in this Article, refers to changes in differential pressure resulting from thermal imbalances and similar phenomena capable of causing a differential pressure change of sufficient duration to be compatible with the dynamic response characteristics of the pressure relief devices listed in this Article.

(b) The basic definitions of pressure relief devices as specified in this Article are given in ASME PTC 25-1994, Safety and Relief Valves.

(c) *Primary Pressure* is the pressure of the fluid at the inlet of the pressure relief device.

(d) *Secondary Pressure* is that value of pressure existing in the passage between the actual discharge area and the outlet for which the discharge system of the pressure relief devices shall be designed.

NE-7120 INTEGRATED OVERPRESSURE PROTECTION

Overpressure protection of the components shall be provided by one of the following methods as an integrated overpressure protection:

(a) the use of vacuum relief or pressure relief devices, or both, and their associated pressure sensing elements; or

(b) a component designed not to exceed Service Limits specified in the Design Specification (pressure relief devices are not required on containment vessels designed and built to safely contain all radioactive substances that may be released into the containment atmosphere).

NE-7130 PROVISIONS FOR CHECKING OPERATION OF PRESSURE RELIEF DEVICES

NE-7131 Design Provisions

Relief devices shall be designed so that potential impairment of the overpressure protection function from service exposure to fluids can be determined by test or examination.

NE-7132 Construction Provisions

Relief devices shall be constructed and installed so that their correct operation and the reliability of their associated pressure sensing elements under service or test conditions can be demonstrated, as may be required by regulatory and enforcement authorities having jurisdiction at the nuclear power plant site.

NE-7140 INSTALLATION PROVISIONS

NE-7141 Installation of Relief Devices

(a) The connection between a component and its pressure relief valve shall have a minimum inside diameter equal to or greater than the nominal size of the pressure relief valve inlet. The opening in the connection shall be designed to provide direct and unobstructed flow between the component and its pressure relief valve. Pressure drop resulting from the accumulated line losses between the protected component and the relief valve shall be compatible with the valve performance characteristic.

(b) Spring-loaded pressure relief valves should normally be installed in the upright position with the spindle vertical. Where space or piping configuration precludes such an installation, the valve may be installed in other than the vertical position, provided the following conditions are met:

(1) the valve design is confirmed by the NV Certificate Holder with documentation as being satisfactory for such position; and

(2) the valve has been pressure tested in the same position as the installation.

(c) The area of the discharge piping from a pressure relief device shall not be less than the area of the discharge connection. The size and length of the discharge piping shall be such that any back pressure that may exist or develop will not reduce the relieving capacity below that required to protect the components.

NE-7142 Provisions When Stop Valves Are Used

No stop valves or other devices shall be placed in the inlet or discharge lines of a relief device so that they could reduce the protection below that required by the rules of this Article, unless such stop valves are constructed and installed with controls and interlocks so that the relieving capacity requirements are met under all conditions of operation. Means shall be provided to verify that the operation of controls and interlocks can be verified.

NE-7150 ACCEPTABLE PRESSURE RELIEF DEVICES

NE-7151 Pressure Relief Valves

Pressure relief valves shall meet the Construction requirements applicable to Class 2 valves.

NE-7152 Vacuum Relief Devices

(a) Vacuum relief devices shall meet the construction requirements applicable to Class 2 valves and the additional requirements of this Article.

(b) Balanced self-actuating, horizontally installed, swinging disk valves, or vertically installed, vacuum disk or pallet-type valves, with provisions for adjustment of the differential pressure under which the valves operate, are acceptable types.

(c) Valve devices intended to provide vacuum relief, and which are operated by indirect means depending upon an external energy source, such as electrical, pneumatic, or hydraulic systems, are not acceptable unless the conditions given in (1) and (2) below are met:

(1) at least two independent external power-operated valve and control systems are employed so that the required relieving capacity is obtained if any one of the valve systems should fail to operate when called upon to do so; and

(2) at least one self-actuating vacuum relief device, of a type specified in (b) above, of equivalent relieving capacity is provided in series with each of the external power-operated valves.

NE-7160 UNACCEPTABLE RELIEF DEVICES

NE-7161 Nonreclosing Pressure Relief Devices

Nonreclosing pressure relief devices are unacceptable.

NE-7200

NE-7200 OVERPRESSURE PROTECTION REPORT

NE-7210 RESPONSIBILITY FOR REPORT

The provisions intended to meet the requirements of this Article shall be the subject of an Overpressure Protection Report prepared by the Owner or his designee.

NE-7220 CONTENT OF REPORT

The Overpressure Protection Report shall define the protected vessel and the integrated overpressure protection provided. As a minimum, the report shall include (a) through (k) below:

(a) identification of specific ASME Section III, Article NE-7000 Edition and Addenda and applicable Code Cases used in the design of the overpressure protection system;

Page 171

(b) drawings showing the arrangement of the protected vessel, including the pressure and/or vacuum relief devices employed;

(c) the range of operating conditions, including the effect of discharge piping back pressure under which the pressure relief devices are required to function;

(d) an analysis of the conditions that give rise to the maximum pressure and/or vacuum relieving requirements;

(e) the relief capacity required to prevent a differential pressure in the vessel in accordance with the requirements in NE-7300;

(f) the operating controls or safety controls of the protected vessel upon which the anticipated required relief capacity of (d) above, and the maximum pressure and temperature of (c) above are predicted;

(g) the redundancy and independence of the pressure and/or vacuum relief devices, and their associated pressure sensors and controls employed to preclude a loss of overpressure protection in the event of a failure of any pressure or vacuum relief device, sensing element, associated control, or external power source;

(h) the design secondary pressure, including a justification of the value identified in the Design Specification for pressure relief devices;

(i) the analysis of pressure transient conditions, including those associated with the response time of pressure and/or vacuum relief devices;

(j) consideration of set pressure and blowdown limitations in accordance with NE-7500, taking into account opening pressure tolerances and overpressure of the pressure relief device;

(k) when pressure relief devices are not required, verification is to include reference to the applicable requirement in NE-3000 that demonstrates that the Service Limits for the vessel do not exceed the Service Limits specified in the Design Specification for all service loadings.

NE-7230 CERTIFICATION OF REPORT

The report, after it has been reconciled with the requirements of this Article, shall be certified by one or more Registered Professional Engineers competent in the applicable field of design and qualified in accordance with the requirements of Appendix XXIII of Section III Appendices.

NE-7240 REVIEW OF REPORT AFTER INSTALLATION

(a) After completion of the installation of the protected vessel an as-built drawing shall be prepared. The Owner or his designee shall review the Overpressure Protection Report against the as-built vessel.

(b) The results of this review shall be documented in an addendum to the Overpressure Protection Report. The addendum shall contain a copy of the as-built drawing and shall include either:

- (1) a statement that the as-built vessel meets the requirements of the Overpressure Protection Report; or
 - (2) a revision to the Overpressure Protection Report to make it agree with the as-built vessel; or
 - (3) a description of the changes made to the as-built vessel to make it comply with the Overpressure Protection Report.
- (c) The addendum shall be certified by one or more Registered Professional Engineers competent in the applicable field of design and qualified in accordance with the requirements of Appendix XXIII of Section III Appendices.

NE-7250 FILING OF REPORT

A copy of the Overpressure Protection Report shall be filed at the nuclear power plant site prior to the Inspector or Authorized Nuclear Inspector signing the Owner's Data Report. The report shall be made available to the Authorized Nuclear Inspector and the enforcement authorities having jurisdiction at the plant site.

NE-7300 RELIEVING CAPACITY REQUIREMENTS

NE-7310 RELIEVING CAPACITY OF PRESSURE RELIEF DEVICES

The total rated relieving capacity of the pressure relief devices shall take into account any limitations due to fluid flow-through piping and other components.

NE-7311 Relieving Capacity of Vacuum Relief Devices

(a) The total rated relieving capacity of the vacuum relief devices shall take into account any limitations due to fluid flow-through piping and other components.

(b) The rated capacity of each vacuum relief device shall not be less than that required to prevent a differential

Page 172

pressure in excess of the value specified in the Design Specification.

(c) At least two independent vacuum relief devices shall be provided on each containment vessel, except on vessels designed to withstand the maximum expected differential pressure. The capacity of each vacuum relief device shall not be less than that required to protect the component.

NE-7400 SET PRESSURES OF PRESSURE RELIEF DEVICES

NE-7410 SET PRESSURE LIMITATIONS FOR TESTING CONDITIONS

The set pressure of the pressure relief devices connected to the vessel shall meet the requirements of NE-6000 and NE-7110.

NE-7500 OPERATING DESIGN REQUIREMENTS FOR PRESSURE RELIEF VALVES

NE-7510 PRESSURE RELIEF VALVES

NE-7511 General Requirements

NE-7511.1 Spring-Loaded Valves.

Valves shall open automatically by direct action of the fluid pressure as a result of forces acting against a spring.

NE-7512 Pressure Relief Valve Operating Requirements

Pressure relief valves shall be constructed to attain rated lift at a pressure which does not exceed the set pressure by more than 10% or 3 psi (20.6 kPa), whichever is greater.

NE-7512.1 Opening Pressure Tolerance

(a) The opening pressure tolerance plus or minus from the set pressure of pressure relief valves shall not exceed 2 psi (13.8 kPa) for pressure up to and including 70 psi (483 kPa) and 3% for pressure above 70 psi (483 kPa).

(b) Conformance with the requirements of (a) above shall be established for each production valve by test. Valves shall be tested with air or gas.

NE-7512.2 Blowdown Requirements.

Pressure relief valves shall be constructed to close after blowing down to a pressure not lower than that specified in the valve Design Specification (NCA-3250). The blowdown shall be determined by test or by proration from the Certificate Holder's blowdown test data.

NE-7513 Relieving Capacity

The relieving capacity of pressure relief valves of the types permitted in this Subarticle shall be based on the stamped relieving capacity and proration of capacity as determined by NE-7700.

NE-7514 Sealing Requirements

Means shall be provided in the construction of all pressure relief valves for sealing all external adjustments. Seals shall be installed by the Certificate Holder at the time of setting. Seals shall be installed in such a manner as to prevent changing the adjustment without breaking the seal and shall serve as a means of identifying the Certificate Holder.

NE-7520 POWER ACTUATED PRESSURE RELIEF VALVES

Power actuated pressure relief valves, which depend upon an external energy source such as electrical, pneumatic, or hydraulic systems, and which respond to signals from pressure or temperature sensing devices may be used provided the following requirements are met.

NE-7521 Sensors and Controls

The relief valve and its auxiliary devices treated as a combination shall comply with the following requirements.

(a) The valve opening pressure shall be controlled within a tolerance of $\pm 1\%$ of the set pressure when the automatic control is in use.

(b) The valve blowdown shall be controlled to a pressure not lower than that specified in the valve Design Specification (NCA-3250).

NE-7522 Relieving Capacity

The total stamped relieving capacity of the valve or valves shall be equivalent to or greater than the required relieving capacity.

Page 173

NE-7700 CERTIFICATION REQUIREMENTS

NE-7710 RESPONSIBILITY FOR CERTIFICATION OF PRESSURE RELIEF VALVES

(a) The Certificate Holder shall be responsible for having the relieving capacity of valves certified as prescribed in this Subarticle.

(b) Capacity certification obtained in compliance with other Sections and which complies with this Section is qualified for capacity certification under these rules, and the valve may be stamped with the appropriate symbol of this Section.

NE-7720 CAPACITY CERTIFICATION OF PRESSURE RELIEF VALVES - COMPRESSIBLE FLUIDS

NE-7721

NE-7721 General Requirements

NE-7721.1 Capacity Certification.

Capacity certification procedures shall be as required in NE-7722 through NE-7727.

NE-7721.2 Test Media.

Capacity certification tests for pressure relief valves for air and gas service shall be conducted with dry saturated steam, air, or gas. For test purposes the limits of 98% minimum quality and 20°F (11°C) maximum superheat shall apply. Capacity shall be corrected to the dry saturated condition from within these limits.

NE-7721.3 Test Pressure.

Capacity certification tests of pressure relief valves for air or gas service shall be conducted at a pressure which does not exceed the set pressure by more than 10% or 3 psi (20.6 kPa), whichever is greater.

NE-7721.4 Blowdown.

Valves having an adjustable blowdown construction shall be adjusted prior to testing so that the blowdown does not exceed 5% of the set pressure.

NE-7721.5 Drawings.

Prior to a test, the Certificate Holder shall submit drawings showing the valve construction to the Authorized Observer. The Authorized Observer shall submit the drawings and test results to the National Board of Boiler and Pressure Vessel Inspectors for capacity certification.

NE-7721.6 Design Change.

When changes are made in the design of a pressure relief valve in such a manner as to affect the flow path, lift, or performance characteristics of the valve, new tests in accordance with this Article shall be performed.

NE-7722 Flow Model Test Method - Power Operated Valves

NE-7722.1 Flow Capacity.

In those cases where test facility limitations make it impossible to perform capacity tests of the full-scale pressure relief valves, flow models of three different sizes may be utilized as a basis for capacity certification. Such flow models shall be sized consistent with the capabilities of the approved test laboratory at which the tests will be conducted and shall accurately model those features which affect flow capacity, such as orifice size, valve lift, and internal flow configuration. The test models need not be functional pressure relief valves, provided other tests to demonstrate proper function of the valve design are conducted as prescribed in NE-7724.1. The relieving capacity of valve designs certified by use of flow models shall be established by the coefficient of discharge method similar to that outlined in NE-7724.1 and NE-7724.2. The certified relieving capacity of all sizes and pressures of a given design for which the value of K has been established, based on flow model tests in accordance with the method of NE-7724, shall not exceed the value calculated by the appropriate formula in NE-7724.2 multiplied by the coefficient K .

NE-7722.2 Demonstration of Function.

The function of three valves of the design to be certified shall be demonstrated by test. Such tests may be performed in conjunction with the capacity certification tests outlined above or as separate tests using production valves. The purpose of these tests is to demonstrate to the satisfaction of a designated representative of the ASME that the valve will achieve full lift and will reclose within the required blowdown. If required by test facility limitations, these tests may be conducted at reduced flow capabilities.

NE-7723 Slope Method

(a) For pressure relief valves of a specific design, four valves of each combination inlet size and orifice size shall be tested. These four valves shall be set at a pressure which will cover the appropriate range of pressures for which the valves are to be used, or set within the range of the authorized test facility.

(b) The instantaneous slope of each test point shall be calculated and averaged where it is defined as the measured capacity divided by the absolute inlet pressure. If any of the experimentally determined slopes fall

Page 174

outside of a range of $\pm 5\%$ of the average slope, the unacceptable valves shall be replaced by two valves of the same size and set pressure. Following the test of these valves, a new average slope shall be determined, excluding the replaced valve test results. If any individual slope is now outside of the $\pm 5\%$ range, then the tests shall be considered unsatisfactory and shall be cause for the ASME designee to refuse certification of the particular valve design. The certified capacity shall be 90% of the average slope multiplied by the flow rating pressure, psia.

NE-7724 Coefficient of Discharge Method

A coefficient K may be established for a specific pressure relief valve design according to the procedure given in NE-7724.1 and NE-7724.2.

NE-7724.1 Number of Valves to Be Tested.

For each design, at least three valves for each of three different sizes shall be submitted for test. Each valve of a given size shall be set at a different pressure.

NE-7724.2 Establishment of Coefficient of Discharge

(a) Tests shall be made on each pressure relief valve to determine its lift, opening and blowdown pressures, and capacity, in terms of the fluid used in the test. A coefficient of discharge K_D shall be established for each test run as follows:

$$K_D = \frac{\text{Actual Flow}}{\text{Theoretical Flow}} = \text{Coefficient of Discharge}$$

Actual Flow is determined quantitatively by test and Theoretical Flow is calculated by the following formula. For tests with dry saturated steam:

$$W_T = 51.5AP$$

where

W_T	= Theoretical Flow, lb/hr
A	= actual discharge area through the valve at developed lift, sq in.
P	= (set pressure $\times$ 1.03) plus atmospheric pressure, psia, or set pressure plus 2 psi plus atmospheric pressure, whichever is greater, for test pressures determined by NB-7731.3(a)
	= (set pressure $\times$ 1.10) plus atmospheric pressure, psia, or set pressure plus 3 psi plus atmospheric pressure, whichever is

greater, for test pressures determined by NB-7731.1(b) or NB-7731.1(c)

(For compressible fluids other than steam, use Appendix XVIII.) The average coefficient of discharge K_D of the tests required shall be multiplied by 0.90 and the product shall be taken as the coefficient K of that design.

(b) If any of the experimentally determined coefficients fall outside of a range of $\pm 5\%$ of the average coefficient, the unacceptable valves shall be replaced by two valves of the same size and set pressure. Following the test of these valves, a new average coefficient shall be determined, excluding the replaced valve test results. If any individual coefficient is now outside of the $\pm 5\%$ range, then the test shall be considered unsatisfactory and shall be cause for the ASME designee to refuse certification of the particular valve design.

NE-7724.3 Calculation of Certified Capacity.

The certified capacity of all sizes and pressures of a given design for which the value of K has been established under the provisions of NE-7724.2, and which are subsequently manufactured, shall not exceed the value calculated by the appropriate formula in NE-7724.2(a) multiplied by the coefficient K .

NE-7725 Single Valve Method

NE-7725.1 Valve Capacity Within Test Facility Limits

(a) Where a single valve is to be capacity tested, the certified capacity may be based on three separate tests associated with each set pressure for which capacity certification is required.

(b) The certified capacity associated with each set pressure shall not exceed 90% of the average capacity established by the tests. Failure of the individual test capacities to fall within $\pm 5\%$ of the average capacity associated with each set pressure shall be cause for rejection of the test. The reason for the failure shall be determined and the test repeated.

(c) Should additional valves of the same design be constructed at a later date, the results of the tests on the original valve may be included as applicable to the particular test method selected.

NE-7725.2 Valve Capacity in Excess of Test Facility Limits

(a) For valves whose capacity exceeds that of the test facility, the certified capacity may be based on a flow coefficient K (NE-7724.2) determined from either blocked open flow tests or flow model tests, provided the orifice area is such that choked flow conditions are obtained. The certified capacity shall be calculated as directed in NE-7724.3.

Page 175

(b) The proper operation of the valve shall be demonstrated as prescribed in NE-7722.2.

NE-7726 Proration of Capacity

(a) The capacity of a pressure relief valve applied to a system may be prorated to an overpressure greater than the overpressure for which the valve design is certified. This overpressure shall be within the allowable limits of the system.

(b) Depending on the method used for the initial capacity certification:

(1) the prorated capacity shall be 90% of the average slope determined in NE-7723 multiplied by the prorated relieving pressure (psia), or;

(2) the prorated capacity shall be calculated using the appropriate formula from NE-7724.2 (where P is the prorated relieving pressure (psia) multiplied by the coefficient K).

NE-7727 Laboratory Acceptance of Pressure Relieving Capacity Tests

Tests shall be conducted at a place where the testing facilities, methods, procedures, and person supervising the tests (Authorized Observer) meet the applicable requirements of ASME PTC 25-1994, Safety and Relief Valves. The tests shall be made under the supervision of, and certified by, an Authorized Observer. The testing facilities, methods, procedures,

and qualifications of the Authorized Observer shall be subject to the acceptance of the ASME Boiler and Pressure Vessel Committee on recommendation of an ASME designee. Acceptance of the testing facility is subject to review within each 5 year period. Capacity test data shall be submitted to the ASME designee for review and acceptance.¹

NE-7730 CAPACITY CERTIFICATION OF VACUUM RELIEF VALVES

NE-7731 General Requirements

NE-7731.1 Capacity Certification.

Capacity certification procedures shall be as required in NE-7732 through NE-7735.

NE-7731.2 Test Media.

Capacity certification tests for vacuum relief valves for air and gas service shall be conducted with dry steam, air, or gas. For steam test purposes the limits of 98% minimum quality and 20°F maximum superheat shall apply. Capacity shall be corrected to dry saturated condition from these limits.

NE-7731.3 Test Method and Pressure.

Capacity tests may be conducted by pressurizing the valve instead of using a vacuum, provided the inlet conditions of the valve (not the vessel) are known and the inlet pressure is not greater than 5 psi (35 kPa), and the direction of flow through the valve is the same on pressure as is experienced on vacuum. Tests shall be conducted at twice the set pressure.

NE-7731.4 Blowdown.

Blowdown shall be recorded at the time of the test.

NE-7731.5 Drawings.

Prior to a test, the Certificate Holder shall submit drawings showing the valve construction to the Authorized Observer. The Authorized Observer shall submit the drawings and test results to the ASME designee for review and acceptance.

NE-7731.6 Design Change.

When changes are made in the design of a pressure relief valve in such a manner as to affect the flow path, lift, or performance characteristics of the valve, new tests in accordance with this Article shall be performed.

NE-7732 Single Valve Method

(a) Where a single valve at a single pressure is to be capacity tested, the capacity rating may be based on three separate and distinct tests of the single valve at the specified set pressure. The certified capacity rating of the valve shall not exceed 90% of the average capacity established by the tests. Failure of the individual test capacities to fall within $\pm 5\%$ of the average capacity shall be cause for rejection of the test. The reason for the failure shall be determined and the test repeated.

(b) Should additional valves of the same design be constructed at a later date, the results of the test on the original valve may be included as applicable to the particular test method selected.

NE-7733 Slope Method

Four valves of each combination of pipe size and orifice size shall be tested. These four valves shall be set at pressures which cover the appropriate range of pressures for which the valves are to be used or set within the range of the test facility. The slope of each test shall be calculated and averaged, where slope is defined as the measured capacity divided by the quantity,

$F [(P)(P - P_o)]^{1/2}$, where

$$F = \sqrt{\left(\frac{k}{k-1}\right) (r^{2/k}) \left[\frac{1 - (r)^{\frac{k-1}{k}}}{1 - r}\right]}$$

P	= inlet pressure, psi
P_o	= discharge pressure, psi
k	= ratio of specific heats, C_v/C_p
r	= pressure ratio, P_o/P

If any of the experimentally determined slopes fall outside of a range of $\pm 5\%$ of the average slope, the unacceptable valves shall be replaced by two valves of the same size and set pressure. Following the test of these new valves, a new average slope shall be determined, excluding the replaced valve test results. If any individual slope is now outside of the $\pm 5\%$ range, then the test shall be considered unsatisfactory and shall be cause for the ASME designee to refuse certification of the particular valve design. The certified capacity shall be 90% of the average slope multiplied by the quantity $F[(P)(P - P_o)]^{1/2}$.

NE-7734 Coefficient of Discharge Method

Instead of individual capacity tests, the capacity curve method of coefficient K may be established for a specific valve design in accordance with NB-7734.1 and NB-7734.2.

NE-7734.1 Number of Valves to Be Tested.

For each design, three valves of three different sizes, a total of nine valves, shall be tested. Each valve of a given size shall be set at a different pressure.

NE-7734.2 Establishment of Coefficient of Discharge

(a) Tests shall be made on each relief valve to determine its lift, opening and closing pressures, and actual capacity. A coefficient of discharge K_D shall be established for each run as follows:

$$K_D = \frac{\text{Actual Flow}}{\text{Theoretical Flow}} = \text{Coefficient of Discharge}$$

where Actual Flow is determined quantitatively by test and Theoretical Flow is calculated from the appropriate equation for the test fluid. The following formula may be used for other than saturated steam flow:

$$W = 735FA \left[\frac{MP(P - P_o)}{T} \right]^{1/2}$$

$$Q = 279,000FA \left[\frac{P(P - P_o)}{MT} \right]^{1/2}$$

where

$$F = \sqrt{\left(\frac{k}{k-1}\right) (r^{2/k}) \left[\frac{1-(r)^{\frac{k-1}{k}}}{1-r}\right]}$$

or is obtained from Fig. NE-7734.2(a)-1.

A	= flow area, sq in.
M	= molecular weight
P	= inlet pressure, psi
P_o	= discharge pressure, psi
T	= temperature, deg Rankin
k	= ratio of specific heats, C_v/C_p
r	= pressure ratio, P_o/P
Q	= cu ft/hr at 14.7 psi and 60°F
W	= lb/hr

The average of the coefficients of discharge K_D of the tests required shall be multiplied by 0.90 and their product shall be the coefficient K of that design. The coefficient of the design shall not be greater than 0.876 (the product of 0.9×0.975).

(b) If any of the experimentally determined coefficients fall outside of a range of $\pm 5\%$ of the average coefficient, the unacceptable valves shall be replaced by two valves of the same size and set pressure. Following the test of these valves, a new average coefficient shall be determined, excluding the replaced valve test results. If any individual coefficient is now outside of the $\pm 5\%$ range, then the test shall be considered unsatisfactory and shall be cause for the ASME designee to refuse certification of the particular valve design.

NE-7734.3 Calculation of Relieving Capacity

(a) The certified relieving capacity of all sizes and pressures of a given design, for which the value of K has been established, shall be calculated by the appropriate formula given above multiplied by the coefficient K . Values obtained from pressurized tests may be converted to equivalent vacuum from the above equation.

(b) The coefficient shall not be applied to valves whose beta ratio (the ratio of valve throat and inlet diameter) lies outside the range of 0.15 to 0.75, unless tests have demonstrated that individual coefficients of discharge, K_D , for valves of the extreme ends of a larger range is within $\pm 5\%$ of the average coefficient,

K. For designs where lift is used to determine the flow area, all valves shall have the same nominal lift-to-seat diameter ratio (L/D).

FIG. NE-7734.2(a)-1 VALUES OF F FOR NONCHOKING FLOW

FIG. NE-7734.2(a)-1 VALUES OF F FOR NONCHOKING FLOW

NE-7735 Laboratory Acceptance of Relieving Capacity Tests

Tests shall be conducted at a place where the testing facilities, methods, procedures, and person supervising the tests (Authorized Observer) meet the applicable requirements of ASME PTC 25-1994. The tests shall be made under the supervision of, and certified by, an Authorized Observer. The testing facilities, methods, procedures, and qualifications of the Authorized Observer shall be subject to the acceptance of the ASME Boiler and Pressure Vessel Committee on recommendation of an ASME designee. Acceptance of the testing facility is subject to review within each 5 year period. Capacity test data shall be submitted to the ASME designee for review and acceptance.¹

NE-7800 MARKING, STAMPING, AND DATA REPORTS

NE-7810 PRESSURE AND VACUUM RELIEF VALVES

¹ Valve capacities published in "Pressure Relief Device Certifications." This publication may be obtained from the National Board of Boiler and Pressure Vessel Inspectors, 1055 Crupper Avenue, Columbus, OH 43229.

NE-7811 Marking and Stamping

Each pressure relief valve shall be plainly marked by the Certificate Holder with the required data below in such a way that the marking will not be obliterated

Page 178

in service. The data shall be in characters not less than $\frac{3}{32}$ in. (2.4 mm) high. The marking shall be placed on the valve or on a nameplate securely fastened to the valve. The Code NV Symbol shall be stamped on the valve or nameplate, but the other required data may be stamped, etched, impressed, or cast. The marking shall include the following:

- (a) name, or an acceptable abbreviation, of the Certificate Holder
- (b) Certificate Holder's design or type number
- (c) size _____ (NPS, the nominal pipe size) of the valve inlet
- (d) set pressure _____ psi
- (e) certified capacity and overpressure in percent or psi in accordance with NE-7700

Pressure Relief Valves:

____ lb/hr of saturated steam for valves certified on steam, or
____ scfm (standard cubic feet per minute) at 60°F (16°C) and 14.7 psia (101 kPa) of air for valves certified on air or gas, or
____ gal/min of water at 70°F (21°C) for valves certified on water

Vacuum Relief Valves:

____ scfh (standard cubic feet per hour) at 60°F (16°C) and 14.7 psi (101 kPa)

- (f) applicable official Code Symbol Stamp, as shown in Table NCA-8100-1

In addition to the above, each pressure relief valve shall have a separate nameplate attached to the component that includes the marking requirements of NCA-8220 and NE-3593.3.

NOTES:

(1) Care should be taken when converting formulas or equations that contain constant terms or factors. The value of these terms must be understood and may also require conversion.

(2)(a) Relationships that are exact in terms of the base units are followed by a single asterisk.

(b) The factors are written as a number greater than 1 and less than 10 with 6 or less decimal places. The number is followed by the letter E (for exponent), a plus or minus symbol, and two digits which indicate the power of 10 by which the number must be multiplied to obtain the correct value. For example: 3.523 907 E-02 is $3.523\ 907 \times 10^{-2}$ or 0.035 239 07.

IMPORTANT INFORMATION ON THE 1998 BOILER AND PRESSURE VESSEL CODE ADDENDA DISTRIBUTION SCHEDULE

There is a change in the way the Addenda to the 1998 Edition of the ASME Boiler and Pressure Vessel Code are distributed. The 1998 Edition, published July 1, 1998, incorporates the 1998 Addenda revisions, additions, or deletions. There will be no separate 1998 Addenda issued in a replacement page format. Two additional Addenda to the 1998 Edition, in the form of replacement pages, will be issued on July 1, 1999 and July 1, 2000.

The Summary of Changes published with the 1998 Edition lists and describes the revisions that are part of the 1998 Addenda. These changes are identified with a margin note, **98**, denoting the affected area.

The Addenda for 1999 and 2000 will also have a Summary of Changes and identifiers printed on the replacement pages. The revisions, additions, or deletions will be incorporated directly into the affected pages. It is advisable to retain the title sheets and all replaced pages for reference.

The effective dates for Code Editions and Addenda are described in the Foreword.

This code or standard was developed under procedures accredited as meeting the criteria for American National Standards. The Standards Committee that approved the code or standard was balanced to assure that individuals from competent and concerned interests have had an opportunity to participate. The proposed code or standard was made available for public review and comment which provides an opportunity for additional public input from industry, academia, regulatory agencies, and the public-at-large.

ASME does not "approve," "rate," or "endorse" any item, construction, proprietary device, or activity.

ASME does not take any position with respect to the validity of any patent rights asserted in connection with any items mentioned in this document, and does not undertake to insure anyone utilizing a standard against liability for infringement of

any applicable Letters Patent, nor assume any such liability. Users of a code or standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, is entirely their own responsibility.

Participation by federal agency representative(s) or person(s) affiliated with industry is not to be interpreted as government or industry endorsement of this code or standard.

ASME accepts responsibility for only those interpretations issued in accordance with governing ASME procedures and policies which preclude the issuance of interpretations by individual volunteers.

The footnotes in this document are part of this American National Standard.

VI Recommended Rules for the Care and Operation of Heating Boilers

VII Recommended Guidelines for the Care of Power Boilers

VIII Rules for Construction of Pressure Vessels

Division 1

Division 2 - Alternative Rules

Division 3 - Alternative Rules for Construction of High Pressure Vessels

IX Welding and Brazing Qualifications

X Fiber-Reinforced Plastic Pressure Vessels

XI Rules for Inservice Inspection of Nuclear Power Plant Components

ADDENDA

Colored-sheet Addenda, which include additions and revisions to individual Sections of the Code, are published annually and will be sent automatically to purchasers of the applicable Sections up to the publication of the 2001 Code. The 1998 Code is available only in the loose-leaf format; accordingly, the Addenda will be issued in the loose-leaf, replacement-page format.

INTERPRETATIONS

ASME issues written replies to inquiries concerning interpretation of technical aspects of the Code. The Interpretations for each individual Section will be published separately and will be included as part of the update service to that Section. They will be issued semiannually (July and December) up to the publication of the 2001 Code. Interpretations of Section III, Divisions 1 and 2, will be included with the update service to Subsection NCA.

CODE CASES

The Boiler and Pressure Vessel Committee meets regularly to consider proposed additions and revisions to the Code and to formulate Cases to clarify the intent of existing requirements or provide, when the need is urgent, rules for materials or constructions not covered by existing Code rules. Those Cases which have been adopted will appear in the appropriate 1998 Code Cases book: (1) Boilers and Pressure Vessels and (2) Nuclear Components. Supplements will be sent automatically to the purchasers of the Code Cases books up to the publication of the 2001 Code.

Page v

FOREWORD

The American Society of Mechanical Engineers set up a committee in 1911 for the purpose of formulating standard rules for the construction of steam boilers and other pressure vessels. This committee is now called the Boiler and Pressure Vessel Committee.

The Committee's function is to establish rules of safety governing the design, fabrication, and inspection during construction of boilers and pressure vessels, and to interpret these rules when questions arise regarding their intent. In formulating the rules, the Committee considers the needs of users, manufacturers, and inspectors of pressure vessels. The objective of the rules is to afford reasonably certain protection of life and property and to provide a margin for deterioration in service so as to give a reasonably long, safe period of usefulness. Advancements in design and material and the evidence of experience have been recognized.

This Code contains mandatory requirements, specific prohibitions, and nonmandatory guidance for construction,¹ and inservice inspection and testing activities. The Code does not address all aspects of these activities and those aspects which are not specifically addressed should not be considered prohibited. The Code is not a handbook and cannot replace education, experience, and the use of engineering judgment. The phrase *engineering judgment* refers to technical judgments made by knowledgeable engineers experienced in the application of the Code. Engineering judgments must be consistent with Code philosophy and such judgments must never be used to overrule mandatory requirements or specific prohibitions of the Code.

¹ Construction, as used in this Foreword, is an all-inclusive term comprising materials, design, fabrication, examination, inspection, testing, certification, and pressure relief.

The Committee recognizes that tools and techniques used for design and analysis change as technology progresses and expects engineers to use good judgment in the application of these tools. The designer is responsible for complying with Code rules and demonstrating compliance with Code equations when such equations are mandatory. The Code neither requires nor prohibits the use of computers for the design or analysis of components constructed to the requirements of the Code. However, designers and engineers using computer programs for design or analysis are cautioned that they are responsible for all technical assumptions inherent in the programs they use and they are responsible for the application of these programs to their design.

The Code does not fully address tolerances. When dimensions, sizes, or other parameters are not specified with tolerances, the values of these parameters are considered nominal and allowable tolerances or local variances may be considered acceptable when based on engineering judgment and standard practice as determined by the engineer.

The Boiler and Pressure Vessel Committee deals with the care and inspection of boilers and pressure vessels in service only to the extent of providing suggested rules of good practice as an aid to owners and their inspectors.

The rules established by the Committee are not to be interpreted as approving, recommending, or endorsing any proprietary or specific design or as limiting in any way the manufacturer's freedom to choose any method of design or any form of construction that conforms to the Code rules.

The Boiler and Pressure Vessel Committee meets regularly to consider revisions of the rules, new rules as dictated by

technological development, Code Cases, and requests for interpretations. Only the Boiler and Pressure Vessel Committee has the authority to provide official interpretations of this Code. Requests for revisions, new rules, Code Cases, or interpretations shall be addressed to the Secretary in writing and shall give full particulars in order to receive consideration and action (see Mandatory Appendix covering preparation of technical inquiries). Proposed revisions to the Code resulting from inquiries will be presented to the Main Committee for appropriate action. The action of the Main Committee becomes effective only after confirmation by letter ballot of the Committee and approval by ASME.

Proposed revisions to the Code approved by the Committee are submitted to the American National Standards Institute and published in *Mechanical Engineering*

Page viii

to invite comments from all interested persons. After the allotted time for public review and final approval by ASME, revisions are published annually in Addenda to the Code.

Code Cases may be used in the construction of components to be stamped with the ASME Code symbol beginning with the date of their approval by ASME.

Code Editions may be used on or after the date of issue shown in the Edition. After Code revisions are approved by ASME, they may be used beginning with the date of issue shown on the Addenda. Revisions to material specifications are originated by the American Society for Testing and Materials (ASTM) and other recognized national or international organizations, and are usually adopted by ASME. However, those revisions may or may not have any effect on the suitability of material, produced to earlier editions of specifications, for use in ASME construction. ASME material specifications approved for use in each construction Code are listed in the Appendices of Section II, Parts A and B. These Appendices list, for each specification, the latest edition adopted by ASME, and earlier and later editions considered by ASME to be identical for ASME construction.

Owners of nuclear power plants are cautioned that Code Editions, Addenda, and Cases to be used in construction shall be acceptable to the regulatory and enforcement authorities having jurisdiction at the nuclear power plant site.

Each state and municipality in the United States and each province in Canada that adopts or accepts one or more Sections of the Boiler and Pressure Vessel Code is invited to appoint a representative to act on the Conference Committee to the Boiler and Pressure Vessel Committee. Since the members of the Conference Committee are in active contact with the administration and enforcement of the rules, the requirements for inspection in this Code correspond with those in effect in their respective jurisdictions. The required qualifications for an Authorized Inspector under these rules may be obtained from the administrative authority of any state, municipality, or province which has adopted these rules.

The Boiler and Pressure Vessel Committee in the formulation of its rules and in the establishment of maximum design and operating pressures considers materials, construction, method of fabrication, inspection, and safety devices. Permission may be granted to regulatory bodies and organizations publishing safety standards to use a complete Section of the Code by reference. If usage of a Section, such as Section IX, involves exceptions, omissions, or changes in provisions, the intent of the Code might not be attained.

Where a state or other regulatory body, in the printing of any Section of the Boiler and Pressure Vessel Code, makes additions or omissions, it is recommended that such changes be clearly indicated.

The National Board of Boiler and Pressure Vessel Inspectors is composed of chief inspectors of states and municipalities in the United States and of provinces in Canada that have adopted the Boiler and Pressure Vessel Code. This Board, since its organization in 1919, has functioned to uniformly administer and enforce the rules of the Boiler and Pressure Vessel Code. The cooperation of that organization with the Boiler and Pressure Vessel Committee has been extremely helpful.

The Code Committee does not rule on whether a component shall or shall not be constructed to the provisions of the Code. The Scope of each Section has been established to identify the components and parameters considered by the Committee in formulating the Code rules. Laws or regulations issued by municipality, state, provincial, federal, or other enforcement or regulatory bodies having jurisdiction at the location of an installation establish the mandatory applicability of the Code rules, in whole or in part, within their jurisdiction. Those laws or regulations may require the use of this Code for vessels or components not considered to be within its Scope or may establish additions or deletions in that Scope. Accordingly, inquiries regarding such laws or regulations are to be directed to the issuing enforcement or regulatory body.

Questions or issues regarding compliance of a specific component with the Code rules are to be directed to the ASME

Certificate Holder (Manufacturer). Inquiries concerning the interpretation of the Code are to be directed to the ASME Boiler and Pressure Vessel Committee. ASME is to be notified should questions arise concerning improper use of an ASME Code symbol.

The specifications for materials given in Section II are identical with or similar to those of specifications published by ASTM, AWS, and other recognized national or international organizations. When reference is made in an ASME material specification to a non- ASME specification for which a companion ASME specification exists, the reference shall be interpreted as applying to the ASME material specification. Not all materials included in the material specifications in Section II have been adopted for use in this Section. Usage is limited to those materials and grades listed in at least one of the tables of Section II, Part D, Subpart 1, identified as applicable to this Section. All materials allowed by this Section and used for construction within the scope of these rules shall be furnished in accordance with material specifications

Page ix

contained in Section II or referenced in Appendices A of Section II, Parts A and B except where otherwise provided in Code Cases or in this Section of the Code. Materials covered by these specifications are acceptable for use in items covered by the Code Sections only to the degree indicated in the applicable Section. Materials for Code use should preferably be ordered, produced, and documented on this basis. Material produced to an acceptable specification with requirements different from the requirements of the corresponding specification listed in Appendix A of Part A or Part B may also be used in accordance with the above, provided the material manufacturer or vessel manufacturer certifies with evidence acceptable to the Authorized Inspector that the corresponding ASME specification requirements of specifications listed in Appendix A of Part A or Part B have been met. Material produced to an acceptable material specification is not limited as to country of origin.

When required by context in this Section, the singular shall be interpreted as the plural, and vice-versa; and the feminine, masculine, or neuter gender shall be treated as such other gender as appropriate.

Publication of the SI (Metric) Edition of the ASME Boiler and Pressure Vessel Code was discontinued with the 1986 Edition. Effective October 1, 1986, the SI Edition was withdrawn as an ASME Boiler and Pressure Vessel Code document.

Page xi

STATEMENT OF POLICY ON THE USE OF CODE SYMBOLS AND CODE AUTHORIZATION IN ADVERTISING

ASME has established procedures to authorize qualified organizations to perform various activities in accordance with the requirements of the ASME Boiler and Pressure Vessel Code. It is the aim of the Society to provide recognition of organizations so authorized. An organization holding authorization to perform various activities in accordance with the requirements of the Code may state this capability in its advertising literature.

Organizations that are authorized to use Code Symbols for marking items or constructions which have been constructed and inspected in compliance with the ASME Boiler and Pressure Vessel Code are issued Certificates of Authorization. It is the aim of the Society to maintain the standing of the Code Symbols for the benefit of the users, the enforcement jurisdictions, and the holders of the symbols who comply with all requirements.

Based on these objectives, the following policy has been established on the usage in advertising of facsimiles of the symbols, Certificates of Authorization, and reference to Code construction. The American Society of Mechanical Engineers does not "approve," "certify," "rate," or "endorse" any item, construction, or activity and there shall be no statements or implications which might so indicate. An organization holding a Code Symbol and/or a Certificate of Authorization may state in advertising literature that items, constructions, or activities "are built (produced or performed) or activities conducted in accordance with the requirements of the ASME Boiler and Pressure Vessel Code," or "meet the requirements of the ASME Boiler and Pressure Vessel Code."

The ASME Symbol shall be used only for stamping and nameplates as specifically provided in the Code. However, facsimiles may be used for the purpose of fostering the use of such construction. Such usage may be by an association or a society, or by a holder of a Code Symbol who may also use the facsimile in advertising to show that clearly specified items will carry the symbol. General usage is permitted only when all of a manufacturer's items are constructed under the rules.

The ASME logo, which is the cloverleaf with the letters ASME within, shall not be used by any organization other than ASME.

STATEMENT OF POLICY ON THE USE OF ASME MARKING TO IDENTIFY MANUFACTURED ITEMS

The ASME Boiler and Pressure Vessel Code provides rules for the construction of boilers, pressure vessels, and nuclear components. This includes requirements for materials, design, fabrication, examination, inspection, and stamping. Items constructed in accordance with all of the applicable rules of the Code are identified with the official Code Symbol Stamp described in the governing Section of the Code.

Markings such as "ASME," "ASME Standard," or any other marking including "ASME" or the various Code Symbols shall not be used on any item which is not constructed in accordance with all of the applicable requirements of the Code.

Items shall not be described on ASME Data Report Forms nor on similar forms referring to ASME which tend to imply that all Code requirements have been met when, in fact, they have not been. Data Report Forms covering items not fully complying with ASME requirements should not refer to ASME or they should clearly identify all exceptions to the ASME requirements.

ORGANIZATION OF SECTION III

1. GENERAL

Section III consists of Division 1, Division 2, and Division 3. These Divisions are broken down into Subsections and are designated by capital letters preceded by the letter "N" for Division 1, by the letter "C" for Division 2, and by the letter "W" for Division 3. The following eleven books make up the three Divisions.

Subsection NCA - General Requirements for Division 1 and Division 2

Division 1

Subsection NB - Class 1 Components

Subsection NC - Class 2 Components

Subsection ND - Class 3 Components

Subsection NE - Class MC Components

Subsection NF - Supports

Subsection NG - Core Support Structures

Subsection NH - Class 1 Components in Elevated Temperature Service

Appendices

Division 2 - Code for Concrete Reactor Vessels and Containments

Division 3 - Containment Systems and Transport Packagings for Spent Nuclear Fuel and High Level Radioactive Waste

Division 2 book includes subsection CC - Concrete Containments and Division 2 Appendices.

Division 3 book includes Subsections WA and WB for General Requirements and Class TP (Type B) Containment, respectively.

2. SUBSECTIONS

Subsections are divided into Articles, Subarticles, paragraphs, and, where necessary, subparagraphs and subsubparagraphs.

3. ARTICLES

Articles are designated by the applicable letters indicated above for the Subsections followed by Arabic numbers, such as NB-1000. Where possible, Articles dealing with the same topics are given the same number in each Subsection in accordance with the following general scheme:

Article Number	Title
1000	Introduction or Scope
2000	Material
3000	Design
4000	Fabrication and Installation
5000	Examination

7000
8000

Testing
Overpressure Protection
Nameplates, Stamping, and Reports

The numbering of Articles and the material contained in the Articles may not, however, be consecutive. Due to the fact that the complete outline may cover phases not applicable to a particular Subsection or Article, the rules have been prepared with some gaps in the numbering.

4. SUBARTICLES

Subarticles are numbered in units of 100, such as NB-1100.

5. SUBSUBARTICLES

Subsubarticles are numbered in units of 10, such as NB-2130, and generally have no text. When a number such as NB-1110 is followed by text, it is considered a paragraph.

6. PARAGRAPHS

Paragraphs are numbered in units of 1, such as NB-2121.

7. SUBPARAGRAPHS

Subparagraphs, when they are *major* subdivisions of a paragraph, are designated by adding a decimal followed by one or more digits to the paragraph number, such as NB-1132.1. When they are *minor* subdivisions of a paragraph, subparagraphs may be designated by lowercase letters in parentheses, such as NB-2121(a).

8. SUBSUBPARAGRAPHS

Subsubparagraphs are designated by adding lowercase letters in parentheses to the *major* subparagraph numbers, such as NB-1132.1(a). When further subdivisions of *minor* subparagraphs are necessary, subsubparagraphs are designated by adding Arabic numerals in parentheses to the subparagraph designation, such as NB-2121(a)(1).

Page xxiv

9. REFERENCES

References used within Section III generally fall into one of the following four categories.

A. References to Other Portions of Section III

When a reference is made to another Article, Subarticle, or paragraph, all numbers subsidiary to that reference shall be included. For example, reference to NB-3000 includes all material in Article NB-3000; reference to NB-3200 includes all material in Subarticle NB-3200; reference to NB-3230 includes all paragraphs NB-3231 through NB-3236.

B. References to Other Sections

Other Sections referred to in Section III are:

Section II, Materials. When a requirement for a material, or for the examination or testing of a material, is to be in accordance with a specification such as SA-105, SA-370, or SB-160, the reference is to material specifications in Section II. These references begin with the letter "S."

Section V, Nondestructive Examination. Section V references begin with the letter "T" and relate to the nondestructive examination of material or welds.

Section IX, Welding and Brazing Qualifications. Section IX references begin with the letter "Q" and relate to welding and brazing requirements.

Section XI, Rules for Inservice Inspection of Nuclear Power Plant Components. When a reference is made to inservice inspection, the rules of Section XI shall apply.

C. Reference to Specifications and Standards Other Than Published in Code Sections

(1) Specifications for examination methods and acceptance standards to be used in connection with them are published by the American Society for Testing and Materials. At the time of publication of Section III, some such specifications were not included in Section II of this Code. A reference to ASTM E 71-64 refers to the specification so designated by and published by ASTM, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

2 The American National Standards Institute (ANSI) was formerly known as the American Standards Association. Standards approved by the Association were designated by the prefix "ASA" followed by the number of the standard and the year of publication. More recently, the American National Standards Institute was known as the United States of America Standards Institute. Standards were designated by the prefix "USAS" followed by the number of the standard and the year of publication. While the letters of the prefix have changed with the name of the organization, the numbers of the standards have remained unchanged.

(2) Dimensional standards covering products such as valves, flanges, and fittings are sponsored and published by the American Society of Mechanical Engineers and approved by the American National Standards Institute.² When a product is to conform to such a standard, for example ANSI B16.5, the standard is approved by the American National Standards Institute. The applicable year of issue is that suffixed to its numerical designation in Table NB-3132-1, for example ANSI B16.5-1977. Standards published by the American Society of Mechanical Engineers are available from ASME, 22 Law Drive, Box 2300, Fairfield, NJ 07007-2300.

(3) Dimensional and other types of standards covering products such as valves, flanges, and fittings are also published by the Manufacturers Standardization Society of the Valve and Fittings Industry and are known as Standard Practices. When a product is required by these rules to conform to a Standard Practice, for example MSS SP-6, the Standard Practice referred to is published by the Manufacturers Standardization Society of the Valve and Fittings Industry, 127 Park Street, N.E., Vienna, VA 22180. The applicable year of issue of such a Standard Practice is that suffixed to its numerical designation in Table NB-3132-1, for example MSS SP-6-1963.

(4) Specifications for welding and brazing materials are published by the American Welding Society, 550 N.W. LeJeune Road, Miami, FL 33135. Specifications of this type are incorporated in Section II and are identified by the AWS designation with the prefix "SF," for example SFA-5.1.

(5) Standards applicable to the design and construction of tanks and flanges are published by the American Petroleum Institute and have designations such as API-620 and API-2000. When documents so designated are referred to in Section III, they are standards published by the American Petroleum Institute.

D. References to Appendices

Two types of Appendices are used in Section III and are designated Mandatory and Nonmandatory.

(1) Mandatory Appendices contain requirements which must be followed in construction; such references are designated by a Roman numeral followed by Arabic numerals. References to II-1100 or XI-3212, for example, relate to the Mandatory Appendices.

(2) Nonmandatory Appendices provide information or guidance for the use of Section III; such references are designated by a capital letter followed by Arabic numerals. A reference to D-1100, for example, relates to a Nonmandatory Appendix.

American Society Of Mechanical Engineers

SEC III D1 NF-1000

ARTICLE NF-1000 INTRODUCTION

Page 1

NF-1100 SCOPE AND GENERAL REQUIREMENTS

NF-1110 ASPECTS OF CONSTRUCTION COVERED BY THESE RULES

(a) Subsection NF contains rules for the material, design, fabrication, examination, installation, and preparation of reports for supports for components and piping which are intended to conform to the requirements for Class 1, 2, 3, and MC construction as set forth in Subsections NB, NC, ND, and NE, respectively, of this Section.

(b) They *do not* cover deterioration which may occur in service as a result of corrosion, erosion, radiation effects, or metallurgical instability of the materials (NCA-1130).

(c) Nuclear power plant supports for which the rules are specified in this Subsection are those metal elements which transmit loads between components (NCA-1210), including piping systems, and intervening elements and the building structure. However, the term *supports* does not encompass a structural element the sole function of which is to carry dynamic loads caused by a postulated loss of pressure retaining integrity.

(d) The Owner shall be responsible for assuring the adequacy of the building structure and all intervening elements in the support load path in accordance with the requirements of NCA-3240 and NCA-3250. To the extent necessary, the support designer shall consider the structural interaction with intervening elements and the building structure.

NF-1120 RULES FOR SUPPORTS AND THEIR CLASSIFICATION

NF-1121 Rules for Supports

The rules of Subsection NF provide requirements for new construction and include consideration of mechanical stresses and effects which result from the constraint of free-end displacements and anchor point motions defined in NF-3121.12 and NF-3121.13, but not thermal or peak stresses.

NF-1122 Classification of Supports

Supports shall be constructed to the requirements of this Subsection that are applicable to the class of the component, including piping system, they are intended to support. Supports may be optionally classified as permitted in NCA-2134. When the components are optionally classified to a higher class as permitted in NCA-2134(d), the support need not be classified to the higher class.

NF-1130 BOUNDARIES OF JURISDICTION

NF-1131 Boundary Between Components and Supports

The jurisdictional boundary between components, including piping systems, and supports shall meet the requirements of NB-1132, NC-1132, ND-1132, or NE-1132 as applicable to the class of component.

NF-1132 Boundary Between Supports and the Building Structure

(a) Supports may bear on or may be welded, bolted, pinned, or clamped to the building structure. Typical examples of jurisdictional boundaries defined between supports and building structures are shown in Figs. NF-1132-1 and NF-1132-2.

(b) The jurisdictional boundary between a support and the load carrying building structure as is the surface of the building structure.

(c) For the purpose of defining the jurisdictional boundary between a support and the building structure, structural members shown on the civil/structural drawings of the plant and considered in the building structural analysis may be designated building structure even

Page 4

though located in the support load path. However, structural members, except as defined in (d) below, detailed on support drawings which are installed and used for the primary purpose of supporting piping or components shall be designated supports and be constructed to the rules of this Subsection. Pages 5-6

GENERAL NOTE:

These sketches are intended to show jurisdictional concepts and should not be considered as recommended configurations.

FIG. NF-1132-1 TYPICAL EXAMPLES OF JURISDICTIONAL BOUNDARIES BETWEEN PIPING SUPPORTS AND THE BUILDING STRUCTURE

FIG. NF-1132-1 TYPICAL EXAMPLES OF JURISDICTIONAL BOUNDARIES BETWEEN PIPING SUPPORTS

GENERAL NOTE:

These sketches are intended to show jurisdictional concepts and should not be considered as recommended configurations.

FIG. NF-1132-1 TYPICAL EXAMPLES OF JURISDICTIONAL BOUNDARIES BETWEEN PIPING SUPPORTS AND THE BUILDING STRUCTURE (CONT'D)

FIG. NF-1132-1 TYPICAL EXAMPLES OF JURISDICTIONAL BOUNDARIES BETWEEN PIPING SUPPORTS AND THE BUILDING STRUCTURE (CONT'D)

GENERAL NOTE:
These sketches are intended to show jurisdictional concepts and should not be considered as recommended configurations.

FIG. NF-1132-1 TYPICAL EXAMPLES OF JURISDICTIONAL BOUNDARIES BETWEEN PIPING SUPPORTS AND THE BUILDING STRUCTURE (CONT'D)

FIG. NF-1132-1 TYPICAL EXAMPLES OF JURISDICTIONAL BOUNDARIES BETWEEN PIPING SUPPORTS AND THE BUILDING STRUCTURE (CONT'D)

GENERAL NOTE:

This sketch is intended to show jurisdictional concepts and should not be considered as a recommended configuration.

FIG. NF-1132-2 TYPICAL EXAMPLE OF JURISDICTIONAL BOUNDARY BETWEEN COMPONENT SUPPORT AND THE BUILDING STRUCTURE

FIG. NF-1132-2 TYPICAL EXAMPLE OF JURISDICTIONAL BOUNDARY BETWEEN COMPONENT SUPPORT AND THE BUILDING STRUCTURE

(d) Surface mounted base plates, with or without grouting; fully or partially embedded steel elements intended to receive loads transmitted by supports; concrete anchors; and hold-down bolts, nuts, and washers shall be designated building structure.

(e) If the means by which the support is connected to the building structure is a weld, the weld shall fall within the jurisdiction of this Subsection.

NF-1133 Boundary Between Supports and Intervening Elements

The jurisdictional boundary between supports and intervening elements in the support load path is the surface of the intervening elements. Supports may bear on or may be welded, bolted, pinned, or clamped to intervening elements. The means by which supports are connected to intervening elements shall fall within the jurisdiction of this Subsection.

NF-1200 TYPES OF SUPPORTS AND ATTACHMENTS

NF-1210 TYPES OF SUPPORTS

NF-1211 General Requirements

In this Subsection all supports are categorized into three separate types based on the general design procedure used for analysis of the support (NF-3140). Requirements for materials, design, fabrication, and examination for each of the three types are provided in the following Articles of this Subsection. These support types are defined in the following paragraphs.

NF-1212 Plate- and Shell-Type Supports

A *Plate- and Shell-Type Support* is a support such as a skirt or saddle which is fabricated from plate and shell elements and is normally subjected to a biaxial stress field.

[98]

NF-1213 Linear-Type Support

A *Linear-Type Support* is defined as acting under essentially a single component of direct stress. Such elements may also be subjected to shear stresses. Examples of such structural elements are tension and compression struts, beams and columns subjected to bending, trusses, frames, rings, arches, and cables. Energy absorbing parts designed to dissipate energy by yielding and which are incorporated into a linear-type piping support shall be constructed in accordance with Appendix NF-III.

[98]

NF-1214 Standard Supports

Typical *Standard Supports* are described in MSS SP-58, Pipe Hangers and Supports, Materials, Design, and Manufacture, which was developed and approved by the Manufacturers Standardization Society of the Valve and Fittings Industry. Typical catalog items are shown in Fig. NF-1214-1. Such units not requiring fabrication by welding shall be considered as material, and may be manufactured and supplied by a Quality System Certificate holder whose scope includes Standard Supports and Catalog items supplied as material including Certification of Load Capacity Data sheets and Design Report summaries. The capacities of standard supports may be determined using plate and shell analysis or linear (working stress) analysis or load rating. Examples of standard supports are:

- (a) rigid supports consisting of anchors, guides, restraints, rolling or sliding supports, and rod-type hangers;
- (b) constant- and variable-type spring hangers;
- (c) snubbers;
- (d) sway braces and vibration dampeners;
- (e) structural attachments such as ears, shoes, lugs, rings, clamps, slings, straps, and clevises.

NF-1215 Primary and Secondary Members

Support members are also categorized as primary or secondary according to function. These member types are defined in the following paragraphs.

(a) *Primary Members.* Primary members of supports are defined as those members designed to carry loads under any postulated load condition.

(b) *Secondary Members.* Secondary members are defined as those members typically used as bracing to maintain primary member system geometry, and which under all loading conditions, are not designed to sustain any significant stress. Significant stress is defined as being in excess of 50% of the allowable stress permitted in the tables of Section II, Part D, Subparts 1 and 2, NF-3300, and applicable Code Cases.

Page 9

Page 10

FIG. NF-1214-1 TYPICAL STANDARD SUPPORT UNITS

NF-1230 WELDING BETWEEN TYPES OF SUPPORTS

NF-1231 Welded Joints Between Plate- and Shell-Type, and Linear-Type Supports

Welded joints between Plate- and Shell-Type Supports (NF-1212), and Linear-Type Supports (NF-1213) shall meet the rules of either Plate- and Shell-Type, or Linear-Type welded joints of this Subsection.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NF-2000

ARTICLE NF-2000 MATERIAL

Page 11

NF-2100 GENERAL REQUIREMENTS FOR MATERIAL

[98]

NF-2110 SCOPE OF PRINCIPAL TERMS EMPLOYED

(a) The term *material* as used in this Subsection is defined in NCA-9000. The term *Material Organization* (Metallic) is defined in NCA-9000.

(b) The requirements of this Article make reference to the term *thickness*. For the purpose intended, the following definitions of nominal thickness apply:

(1) *plate* - the thickness is the dimension of the short transverse direction

(2) *forgings* - the thickness is the dimension defined as follows:

(a) *hollow forgings* - the nominal thickness is measured between the inside and outside surfaces (radial thickness)

(b) *disk forgings* (axial length less than the outside diameter) - the nominal thickness is the axial length

(c) *flat ring forgings* (axial length less than the radial thickness) - for axial length ≤ 2 in. (51 mm), the axial length is the nominal thickness. For axial length > 2 in. (51 mm), the radial thickness is the nominal thickness

(d) *rectangular solid forgings* - the least rectangular dimension is the nominal thickness

(3) *castings* - thickness, t , is defined as the largest nominal thickness of the load carrying portion of the casting.

[98]

NF-2120 SUPPORT MATERIAL

NF-2121 Permitted Material Specifications

(a) Except as provided in (b) below, material for supports shall conform to the requirements of the specifications for material listed in the tables of Section II, Part D applicable to the Class of construction, as indicated in Table NF-2121(a)-1.

(b) The requirements of this Article do not apply to items such as gaskets, seals, bushings, wire rope used as a spring, springs, compression spring end plates, bearings, retaining rings, washers, wear shoes, shims, slide plates, hydraulic fluids, etc., or to material used for stops¹ for seismic and other dynamic loads that are designed primarily for compressive loading and are not connected to the support or the pressure boundary. Requirements, if any, for these materials shall be stated in the Design Specifications (NCA-3250). Such items shall be made of material that is not injuriously affected by the fluid, temperature, irradiation, or impact loading conditions to which the item will be subjected. The support manufacturer shall

provide the Owner with a list of such materials. These materials do not require Material Organizations' Certificates of Compliance (NF-2130).

(c) Welding and brazing material used in manufacture of items shall comply with an SFA Specification in Section II, Part C, except as otherwise permitted in Section IX, and shall also comply with the applicable requirements of this Article. The requirements of this Article do not apply to materials used as backing rings or backing strips in welded joints.

1 Stops do not include snubbers [NF-1130(e)].

NF-2122 Special Requirements Conflicting With Permitted Material Specifications

(a) Special requirements stipulated in this Article shall apply in lieu of the requirements of the material specifications wherever the special requirements conflict with the material specification requirements [NCA-3856.3(d)]. Where the special requirements include an examination, test, or treatment which is also required by the material specification, the examination, test, or treatment need be performed only once. Required nondestructive examinations shall be performed as specified

Page 16

for each product form in NF-2500. Any examination, repair, test, or treatment required by the material specification or by this Article may be performed by the Material Organization or the Certificate Holder, as provided in NF-4121.1. Pipe or tube material used under the rules of this Subsection need not be hydrostatically or pneumatically tested, provided these materials are not used in a pressure retaining function.

NOTES:

- (1) Table Y-2 provides permanent strain limiting factor for plate- and shell-type supports.
- (2) Tables TE and TM provide values of the coefficient of thermal expansion and modulus of elasticity, respectively.
- (3) Multiply tabulated values by 3 to arrive at S_y values. Round up to the next higher 0.5 ksi.

TABLE NF-2121(a)-1 MATERIAL TABLES REQUIRED FOR SUPPORTS^{1,2}

(b) Copper and copper based alloys shall not be used for structural members.

NF-2124 Size Ranges

Material outside the limits of size or thickness given in any specification in Section II may be used if the material is in compliance with the other requirements of the specification and no size limitation is given in the rules for construction. In those specifications in which chemical composition or mechanical properties are indicated to vary with size or thickness, any material outside the specification range shall be required to conform to the composition and mechanical properties shown for the nearest specified range [NCA-3856.3(d)].

NF-2130 CERTIFICATION OF MATERIAL

(a) Material used in the construction of supports shall be certified. Certified Material Test Reports in accordance with NCA-3862 shall be provided for material used for primary members for Class 1 Plate- and Shell-Type Supports, and Class 1 Linear-Type Supports. Material for other Classes of supports and all Classes of Standard Supports shall be provided with Certified Material Test Reports when impact testing is required (NF-231 I). Copies of these certificates shall be provided with the support.

(b) Certificates of Compliance with the material specification, grade, class, and heat treated condition, as applicable, or Certified Material Test Reports shall be provided by the Material Organization for material for all other supports, Standard Supports, and secondary members of all types and Classes of supports.

(c) When Design Documents, such as the Design Report or Load Capacity Data Sheet, permit the use of alternative materials for which certificates of compliance are permitted, the alternative materials may be documented in the Design Documents or the documentation for the support in lieu of documenting the specific material used. The requirements of NF-2150 for identification of materials shall apply.

(d) When material Certificates of Compliance are permitted, the support manufacturer or the support Material Organization who furnishes material (NCA-1221) for supports or supports as material (NF-1214), shall transmit copies of the material Certificates of Compliance applicable to each support. Alternatively, he shall execute and furnish a single document certifying a listing of all material specifications involved in the shipment. When a single document is furnished, his quality program shall provide for his retention of the material Certificates of Compliance for each of the materials incorporated into the supports.

NF-2140 WELDING MATERIAL

For the requirements governing the material to be used for welding, see NF-2400.

NF-2150 MATERIAL IDENTIFICATION

The identification of material requiring Certified Material Test Reports shall meet the requirements of NCA-3856. Material furnished with Certificates of Compliance shall be identified by a controlled system meeting the requirements of the applicable material specification, grade, and class. Identification of the material to the Material Organization's Certificate of Compliance is not required after the support manufacturer, or the Material Organization who furnishes supports as material (NF-1214), has verified that the material meets the requirements of this Section. Material for small items shall be controlled during the manufacture of the supports so that they are identifiable as acceptable material at all times. Welding material shall be controlled during the repair of material and the manufacture and installation of supports so that it is identifiable as acceptable material until the material is actually consumed in the process (NF-4122).

NF-2160 DETERIORATION OF MATERIAL IN SERVICE

Consideration of deterioration of material caused by service is generally outside the scope of this Subsection. It is the responsibility of the Owner to select material suitable for the conditions stated in the Design Specifications (NCA-3250), with specific attention being given to the effect of Service Conditions upon the properties of the material.

NF-2170 HEAT TREATMENT TO ENHANCE IMPACT PROPERTIES

Carbon steel, low alloy steels, and high alloy chromium (Series 4XX) steels may be heat treated by quenching and tempering to enhance their impact properties. Postweld heat treatment of the support at a temperature of not less than 1100°F (593°C) may be considered to be the tempering phase of the heat treatment.

NF-2180 PROCEDURES FOR HEAT TREATMENT OF MATERIAL

When heat treating temperature or time is required by the material specification and the rules of this Subsection, the heat treating shall be performed in temperature-surveyed and -calibrated furnaces or the heat treating shall be controlled by measurement of material temperature thermocouples in contact with the material or attached to blocks in contact with the material or by calibrated pyrometric instruments. Heat treating shall be performed under furnace loading conditions such that the heat treatment is in accordance with the material specification and the rules of this Subsection.

NF-2200 MATERIAL TEST COUPONS AND SPECIMENS FOR FERRITIC STEEL MATERIAL

NF-2210 HEAT TREATMENT REQUIREMENTS

2 Any postweld heat treatment time which is anticipated to be applied to the material or item after it is completed shall be specified in the Design Specifications. The Certificate Holder shall include this time in the total time at temperature specified to be applied to the test specimens.

NF-2211 Test Coupon Heat Treatment for Ferritic Material²

If ferritic steel material is subjected to heat treatment during construction of a support, the material used for the impact test specimens shall be heat treated in the same manner as the support, except that test coupons and specimens for P-No. 1 material with a nominal thickness of 2 in. (51 mm) or less are not required to be so heat treated. The support manufacturer shall provide the Material Organization with the temperature and heating and cooling rate to be used. In the case of postweld heat treatment, the total time at temperature or temperatures for the test material shall be at least 80% of the total time at temperature or temperatures during actual postweld heat treatment of the material, and the total time at temperature or temperatures for the test material, coupon, or specimen may be performed in a single cycle.

NF-2212 Test Coupon Heat Treatment for Quenched and Tempered Material

NF-2212.1 Cooling Rates.

When ferritic steel material is subjected to quenching from the austenitizing temperature, the test coupons representing those materials shall be cooled at a rate similar to and no faster than the main body of the material except in the case of certain forgings and castings (NF-2223.3 and NF-2226.4). This rule shall apply for coupons taken directly from the material as well as for separate test coupons representing the material, and one of the general procedures described in NF-2212.2 or one of the specific procedures described in NF-2220 shall be used for each product form.

NF-2212.2 General Procedures.

One of the general procedures in (a), (b), and (c) below may be applied to quenched and tempered material or test coupons representing the material, provided the specimens are taken relative to the surface of the product in accordance with NF-2220. Further specific details of the methods to be used shall be the obligation of the Material Organization and the Certificate Holder.

(a) Any procedure may be used which can be demonstrated to produce a cooling rate in the test material that matches the cooling rate of the main body of the product within 25°F (14°C) and 20 sec at all temperatures after cooling begins.

(b) If cooling rate data for the material and cooling rate control devices for the test specimens are available, the test specimens may be heat treated in the device to represent the material, provided that the provisions of (a) above are met.

(c) When any of the specific procedures described in NF-2220 are used, faster cooling rates at the edges may be compensated for by:

- (1) taking the test specimens at least t from a quenched edge, where t equals the material thickness;
 - (2) attaching a steel pad at least t wide by a partial penetration weld (which completely seals the buffered surface) to the edge where specimens are to be removed; or
 - (3) using thermal barriers or insulation at the edge where specimens are to be removed.
-

It shall be demonstrated (and this information shall be included in the Certified Material Test Report) that the cooling rates are equivalent to (a) or (b) above.

NF-2220 PROCEDURE FOR OBTAINING TEST COUPONS AND SPECIMENS FOR QUENCHED AND TEMPERED MATERIAL

NF-2221 General Requirements

The procedure for obtaining impact test specimens for quenched and tempered material is related to the product form. Coupon and specimen location shall be as required by the material specification, except as stated in the following paragraphs of this Subarticle. References to dimensions signify nominal values.

NF-2222 Plates

NF-2222.1 Number of Tension Test Coupons.

The number of tension test coupons required shall be in accordance with the material specification and with SA-20, except that from carbon steel plates weighing 42,000 lb (20,050 kg) and over and alloy steel plates weighing 40,000 lb (18,140 kg) and over, two tension test coupons shall be taken, one representing the top end of the plate and one representing the bottom end of the plate.

NF-2222.2 Orientation and Location of Coupons.

Coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from a rolled surface and with the midlength of the specimen at least t from any heat treated edge, where t is the nominal thickness of the material. The orientation of the coupons shall be as specified in the material specification.

NF-2222.3 Requirements for Separate Test Coupons.

Where a separate test coupon is used to represent the support material, it shall be of sufficient size to ensure that the cooling rate of the region from which the test coupons are removed represents the cooling rate of the material at least $\frac{1}{4}t$ deep and t from any edge of the product. Unless cooling rates applicable to the bulk pieces or product are simulated in accordance with NF-2212.2(b), the dimensions of the coupon shall not be less than $3t \times 3t \times t$, where t is the nominal material thickness.

NF-2223 Forgings

NF-2223.1 Location of Coupons.

Coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from any surface and with the midlength of the specimens at least t from any second surface, where t is the maximum heat treated thickness. A thermal buffer as described in NF-2212.2(c) may be used to achieve these conditions, unless cooling rates applicable to the bulk forgings are simulated as otherwise provided in NF-2212.2.

NF-2223.2 Very Thick and Complex Forgings.

Test coupons for forgings which are both very thick and complex, such as trunnions, support forgings, flanges, and other complex forgings that are contour shaped or machined to essentially the finished product configuration prior to heat treatment, may be removed from prolongations or other stock provided on the product. The Certificate Holder shall

specify the surfaces of the finished product subjected to high tensile stresses in service. The coupons shall be taken so that specimens shall have their longitudinal axes at a distance below the nearest heat treated surface, equivalent to at least the greatest distance that the indicated high tensile stress surface will be from the nearest surface during heat treatment, and with the midlength of the specimens a minimum of twice this distance from a second heat treated surface. In any case, the longitudinal axes of the specimens shall not be nearer than $\frac{3}{4}$ in. to any heat treated surface and the midlength of the specimens shall be at least $1\frac{1}{2}$ in. from any heat treated surface.

NF-2223.3 Coupons From Separately Produced Test Forgings.

Test coupons representing forgings from one heat and one heat treatment lot may be taken from a separately forged piece under the conditions given in (a) through (e) below.

(a) The separate test forging shall be of the same heat of material and shall be subjected to substantially the same reduction and working as the production forging it represents.

(b) The separate test forging shall be heat treated in the same furnace charge and under the same conditions as the production forging.

(c) The separate test forging shall be of the same nominal thickness as the production forging.

(d) Test coupons for simple forgings shall be taken so that specimens shall have their longitudinal axes at the region midway between midthickness and the surface and with the midlength of the specimens no nearer to any heat treated edge than a distance equal to the forging thickness, except when the thickness-length ratio of the production forging does not permit, in which case a production forging shall be used as the test forging and the midlength of the specimens shall be at the midlength of the test forgings.

Page 20

(e) Test coupons for complex forgings shall be taken in accordance with NF-2223.2.

NF-2223.4 Test Specimens for Forgings.

When test specimens for forgings are to be taken under the applicable specification, the Inspector shall have the option of witnessing the selection, placing an identifying stamping on them, and witnessing the testing of these specimens.

NF-2224 Location of Coupons

(a) *Bars.* Coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from the outside or rolled surface and with the midlength of the specimens at least t from a heat treated end, where t is either the bar diameter or thickness.

(b) *Bolting Material.* For bolting material, the coupons shall be taken in conformance with the applicable material specification and with the midlength of the specimen at least one diameter or thickness from a heat treated end. When the studs, nuts, or bolts are not of sufficient length, the midlength of the specimen shall be at the midlength of the studs, nuts, or bolts. The studs, nuts, or bolts selected to provide test coupon material shall be identical with respect to the quenched contour and size, except for length, which shall equal or exceed the length of the represented studs, nuts, or bolts.

NF-2225 Tubular Products and Fittings

NF-2225.1 Location of Coupons.

Coupons shall be taken so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ from the inside or outside surface and with the midlength of the specimens at least t from a heat treated end, where t is the nominal wall thickness of the tubular product.

NF-2225.2 Separately Produced Coupons Representing Fittings.

Separately produced test coupons representing fittings may be used. When separately produced coupons are used, the requirements of NF-2223.3 shall be met.

NF-2226 Castings

NF-2226.1 Castings With 2 in. (51 mm) Maximum Thickness and Less.

For castings with a maximum thickness of 2 in. (51 mm) and less, the specimens shall be taken from either the standard separately cast coupons or the casting, in accordance with the material specification.

NF-2226.2 Castings With Thicknesses Exceeding 2 in. (51 mm) Maximum Thickness.

For castings exceeding a thickness of 2 in. (51 mm), the coupons shall be taken from the casting (or an extension of it) so that specimens shall have their longitudinal axes at least $\frac{1}{4}t$ of the maximum heat treated thickness from any surface and with the midlength of the specimens at least t from any second surface. A thermal buffer may be used [NF-2212.2 (c)(3)].

NF-2226.3 Separately Cast Test Coupons for Castings With Thicknesses Exceeding 2 in. (51 mm).

In lieu of the requirements of NF-2226.2, separately cast test coupons may be used under the conditions of (a), (b), and (c) below.

(a) The separate test coupon representing castings from one heat and one heat treated lot shall be of the same heat of material and shall be subjected to substantially the same foundry practices as the production casting it represents.

(b) The separate test coupon shall be heat treated in the same furnace charge and under the same conditions as the production casting, unless cooling rates applicable to the bulk castings are simulated in accordance with NF-2212.2.

(c) The separate test coupon shall not be less than $3t \times 3t \times t$, where t equals the nominal thickness of the casting. Test specimens shall be taken with their longitudinal axes at the region midway between midthickness and the surface and with the midlength of the specimens no nearer any heat treated edge than a distance equal to the casting thickness.

NF-2226.4 Castings Machined or Cast to Finished Configuration Before Heat Treatment.

In lieu of the requirements of NF-2226.1, NF-2226.2, or NF-2226.3, test coupons may be removed from prolongations or other stock provided on the product. The coupons shall be taken so that specimens shall have their longitudinal axes at a distance below the nearest heat treated surface equivalent at least to the greatest distance that the indicated high tensile stress surface will be from the nearest surface during heat treatment and with the midlength of the specimens a minimum of twice this distance from a second heat treated surface. In any case, the longitudinal axes of the specimens shall be at least $\frac{3}{4}$ in. (19 mm) from any heat treated surface and the midlength of the specimens shall be at least $1\frac{1}{2}$ in. (38 mm) from any second heat treated surface. The Certificate Holder shall specify the surfaces of the finished product subjected to high tensile stresses in service.

Page 21

NF-2227 Rolled Shapes

For rolled shapes, the coupons shall be taken so that specimens shall have their longitudinal axes on a line representing the center of the thickest element of the shape and with the midlength of the specimen at least t from a heat treated end.

NF-2300 FRACTURE TOUGHNESS REQUIREMENTS FOR MATERIAL

NF-2310 MATERIAL TO BE IMPACT TESTED

NF-2311 Supports for Which Impact Testing of Material Is Required³

(a) Support materials shall be impact tested in accordance with the requirements listed below.

(1) Attachments to the component or piping shall meet the requirements for impact testing stipulated in the applicable Subsection.

(2) Class 1, 2, 3, and MC component supports shall meet the requirements of NF-2300.

(3) For Class 1, 2, and 3 piping supports, Class 1, 2, 3, and MC Standard Supports, and all other types and Classes of supports, the Design Specification (NCA-3250) shall state whether or not impact testing is required for the material of which the support is constructed. When impact testing is required, the tests shall meet the requirements of NF-2300 for Class 1, 2, 3, or MC, respectively and shall become a requirement of this Subsection.

(b) The requirements for supports shall be as specified in NF-2300, except that the materials described in (1) through (13) below are not to be impact tested as a requirement of this Subsection:

- (1) material with a nominal section thickness of $\frac{5}{8}$ in. and less;
- (2) bolting, including studs, nuts, and bolts, with a nominal size of 1 in. (25 mm) and less;
- (3) bars with a nominal cross-sectional area of 1 sq in. (645 mm²) and less;
- (4) material for fittings with all pipe connections of $\frac{5}{8}$ in. (16 mm) nominal wall thickness and less;
- (5) austenitic stainless steels;
- (6) nonferrous materials;

3 When impact testing is required, the methods of Appendix G (Section III, Division 1, Appendices) may be used as an alternative design procedure for assuring protection against nonductile fracture.

**TABLE NF-2311(b)-1
EXEMPTIONS FROM IMPACT TESTING UNDER
NF-2311(b)(9) AND (10) FOR MATERIAL
THICKNESS TO 2½ in., INCLUSIVE**

Material [Note (1)]	Material Condition [Note (1)]	T_{NDT} , °F [Notes (2), (3)]
SA-537, Class 1	N	-30
SA-516, Grade 70	Q & T	-10
SA-516, Grade 70	N	0
SA-508, Class 1	Q & T	+10
SA-533, Grade B	Q & T	+10
SA-299 [Note (4)]	N	+20
SA-216, Grades WCB, WCC	Q & T	+30
SA-36 (Plate)	HR	+40
SA-508, Class 2	Q & T	+40

NOTES:

- (1) Material Condition letters refer to:
N = Normalize
Q & T = Quench and Temper
HR = Hot Rolled
- (2) These values for T_{NDT} were established from data on heavy section steel (thickness greater than 2½ in.). Values for sections less than 2½ in. thick are held constant until additional data are obtained.
- (3) T_{NDT} = temperature at or above nil-ductility transition temperature (ASTM E 208-91); T_{NDT} is 10°F below the temperature at which at least two specimens show no-break performance.
- (4) Materials made to a fine grain melting practice.

TABLE NF-2311(b)-1 EXEMPTIONS FROM IMPACT TESTING UNDER NF-2311(b)(9) AND (10) FOR MATERIAL THICKNESS TO $2\frac{1}{2}$ in., INCLUSIVE

- (7) material for supports when the maximum stress does not exceed 6000 psi (41 MPa) tension or is compressive;
- (8) rolled structural shapes, when the thickness of a flange is $\frac{5}{8}$ in. (16 mm) or less;
- (9) materials for Class 1, 2, or MC supports, listed in Table NF-2311(b)-1, for thicknesses $2\frac{1}{2}$ in. (64 mm) and less when the Lowest Service Temperature⁴ is at least 30°F (17°C) above the tabulated temperature. This exemption from impact testing does not apply to either the weld metal (NF-2430) or the weld procedure qualification (NF-4335).

⁴ Lowest Service Temperature (LST) is the minimum temperature which will be maintained inside the containment vessel during the plant operation (for supports within containment), or alternatively, the calculated or measured minimum metal temperature of the support expected during normal operation when the pressure within the component exceeds 20% of the system hydrostatic test pressure.

- (10) materials for Class 3 supports, listed in Table NF-2311(b)-1, for thicknesses $2\frac{1}{2}$ in. (64 mm) and less, when the Lowest Service Temperature is equal to or greater than the tabulated temperature. This exemption from impact testing does not apply to either the

Page 22

weld metal (NF-2430) or the weld procedure qualification (NF-4335).

- (11) materials for Class 2 and MC supports for which the Lowest Service Temperature exceeds 150°F (66°C);
- (12) materials for Class 3 supports for which the Lowest Service Temperature exceeds 100°F (38°C);
- (13) Materials for Class 2, 3, and MC supports for which the Lowest Service Temperature (LST) is equal or above the Minimum Design Metal Temperature of Fig. NF-2311(b)-1 for the materials listed and the applicable material thicknesses.

(c) The Design Specification (NCA-3250) shall state the Lowest Service Temperature (LST) for the support and the designated impact test temperature, when required.

NF-2320 IMPACT TEST PROCEDURES

NF-2321 Charpy V-Notch Tests

The Charpy V-notch test (C_v), when required, shall be performed in accordance with SA-370. Specimens shall be in accordance with SA-370, Fig. 11, Type A. A test shall consist of a set of three full-size 10 mm × 10 mm specimens. The lateral expansion and absorbed energy, as applicable, and the test temperature, as well as the orientation and location of all tests performed to meet the requirements of NF-2330 shall be reported in the Certified Material Test Report.

NF-2322 Location and Orientation of Test Specimens

Impact test specimens for quenched and tempered material shall be removed from the locations and orientation specified for tensile test specimens in each product form in NF-2220 except that for plates the orientation of the impact test specimens shall be longitudinal. For material in other heat treated conditions, impact test specimens shall be removed from the locations and orientations specified for tensile test specimens in the material specification except that for plates the orientation of the impact specimens shall be longitudinal, and for structural shapes the location and orientation of the impact test specimens shall be as specified in ASTM Specification A 673-77. Alternatively, the orientation may be in the direction of maximum stress regardless of heat treatment. For bolting, the C_v impact test specimens shall be prepared with the longitudinal axis of the specimen located at least one-half radius or 1 in. (25 mm) below the surface plus the machining allowance per side, whichever is less. The fracture plane of the specimen shall be at least one diameter or thickness from the heat treated end. When the studs, nuts, or bolts are not of sufficient length, the midlength of the specimen shall be at the midlength of the studs, nuts, or bolts. The studs, nuts, or bolts selected to provide test coupon material shall be identical with respect to the quenched contour and size, except for length, which shall equal or exceed the length of the represented studs, nuts, or bolts. For all material, the number of tests shall be in accordance with NF-2340.

NF-2330 TEST REQUIREMENTS AND ACCEPTANCE STANDARDS

NF-2331 Material (Excluding Bolting)

When impact testing is required, material (other than bolting) shall be tested as required by (a) and (b) below.

(a) Test three C_v specimens at the designated temperature (NF-2311). All three specimens shall meet one of the acceptance standards applicable to the specific test method.

(1) *Charpy V-Notch Testing for Lateral Expansion Values.* The test results of the three specimens, collectively and singly, shall meet the respective requirements of Table NF-2331(a)-1 for Class 1, of Table NF-2331(a)-2 for Class 2 and MC, and of Table NF-2331(a)-3 for Class 3 supports.

(2) *Charpy V-Notch Testing for Absorbed Energy Values.* The test results of the three specimens, collectively and singly, shall meet the respective requirements of Table NF-2331(a)-4 for Class 1, of Fig. NF-2331(a)-1 for Class 2 and MC, and of Fig. NF-2331(a)-2 for Class 3 supports.

(b) Apply the procedures of (a) above to:

(1) base material;

(2) the base material, the heat affected zone, and weld metal from the weld procedure qualification tests of NF-4330; and

(3) the weld metal of NF-2431.

NF-2333 Bolting Material

When impact testing is required, for bolting material including studs, nuts, and bolts, test three C_v specimens at the designated temperature. All three specimens shall meet the requirements of Table NF-2333-1.

TABLE NF-2331(a)-3 REQUIRED C_v LATERAL EXPANSION VALUES FOR CLASS 3 SUPPORT MATERIAL OTHER THAN BOLTING

NF-2340 NUMBER OF IMPACT TESTS REQUIRED

NF-2341 Plates

One test shall be made from each plate as heat treated. Where plates are furnished in the unheat-treated condition and qualified by heat treated test specimens, one test shall be made for each plate as-rolled. The term *as-rolled* refers to the plate rolled from a slab or directly from an ingot, not to its heat treated condition.

NF-2342 Forgings and Castings

(a) Where the weight of an individual forging or casting is less than 1000 lb (454 kg), one test shall be made to represent each heat in each heat treatment lot.

(b) When heat treatment is performed in a continuous-type furnace with suitable temperature controls and equipped with recording pyrometers so that complete heat treatment records are available, a heat treatment lot shall be considered as the lesser of a continuous run not exceeding 8 hr duration or a total weight, so treated, not exceeding 2000 lb (907 kg).

(c) One test shall be made for each forging or casting of 1000 to 10,000 lb (454 kg to 4540 kg) in weight.

(d) As an alternative to (c), a separate test forging or casting may be used to represent forgings or castings of different sizes in one heat and heat treat lot, provided the test piece is a representation of the greatest thickness in the heat treat lot. In addition, test forgings shall have been subjected to substantially the same reduction and working as the forgings represented.

FIG. NF-2331(a)-1 REQUIRED C_v ENERGY VALUES FOR CLASS 2 AND MC SUPPORT MATERIAL OTHER THAN BOLTING

GENERAL NOTES:

- (a) Interpolation between yield strengths shown is permitted.
- (b) The lowest of three specimens tested shall not be less than 5 ft-lbf below the average value -- required.

FIG. NF-2331(a)-2 REQUIRED C_v ENERGY VALUES FOR CLASS 3 SUPPORT MATERIAL OTHER THAN BOLTING

FIG. NF-2331(a)-2 REQUIRED C_v ENERGY VALUES FOR CLASS 3 SUPPORT MATERIAL OTHER THAN BOLTING

**TABLE NF-2333-1
REQUIRED C_v VALUES
FOR BOLTING MATERIAL**

Nominal Diameter, in.	Lateral Expansion, mils
1 or less	No test required
Over 1	25

TABLE NF-2333-1 REQUIRED C_v VALUES FOR BOLTING MATERIAL

(e) Forgings or castings larger than 10,000 lb (4540 kg) shall have two tests per part for Charpy V-notch. The location of C_v impact test specimens shall be selected so that an equal number of specimens is obtained from positions in the forging or casting 180 deg. apart.

(f) As an alternative to (e) for static castings, a separately cast test coupon (NF-2226.3) may be used; one test shall be made for Charpy V-notch.

NF-2343 Bars and Rolled Shapes

(a) For bars, one test shall be made for each diameter or size greater than 1 in. in each lot, where a lot is defined as one heat of material:

- (1) as-rolled in one continuous operation; or
- (2) heat treated in one charge, or each 6000 lb (2720 kg) or less from one continuous operation.

(b) For rolled shapes, the frequency of testing shall be one test (a set of three specimens) for at least each 15 tons (13,608 kg) or each single length of 15 tons (13,608 kg) or more, of the same nominal shape size, excluding length, for each heat in the as-rolled condition. If the shapes are heat treated, one test shall be taken from each heat of each nominal shape size, excluding length, in each furnace lot. For shapes heat treated in a continuous furnace, a lot shall not exceed 15 tons (13,608 kg).

NF-2344 Tubular Products and Fittings

On products which are seamless or welded without filler metal, one test shall be made from each lot. On products which are welded with filler metal, one additional test with the specimens taken from the weld area shall also be made on each lot. A lot shall be defined as stated in the applicable material specification, but in no case shall a lot consist of products from more than one heat of material and of more than one diameter, with the nominal thickness of any product included not exceeding that to be impact tested by more than $\frac{1}{4}$ in. (6 mm); such a lot shall be in a single heat treatment load or in

the same continuous run in a continuous furnace controlled within a 50°F (28°C) range and equipped with recording pyrometers.

NF-2345 Bolting Material

One test shall be made for each lot of material where a lot is defined as one heat of material heat treated in one charge or as one continuous operation, not to exceed in weight the following:

1 ³ / ₄ in. diameter and less	1,500 lb
Over 1 ³ / ₄ in. to 2 ¹ / ₂ in. diameter	3,000 lb
Over 2 ¹ / ₂ in. to 5 in. diameter	6,000 lb
Over 5 in. diameter	10,000 lb

NF-2350 RETESTS

NF-2351 Retests for Class 1, 2, 3, and MC Material Other Than Bolting

(a) For Charpy V-notch tests required by NF-2331 to meet the acceptance standards of Tables NF-2331(a)-1, NF-2331(a)-2, and NF-2331(a)-3, respectively, one retest at the same temperature may be conducted, provided:

- (1) the average value of the test results meets the minimum requirements;
- (2) not more than one specimen per test is below the minimum requirements;
- (3) the specimens not meeting the minimum requirements are not lower than 5 mils (0.13 mm) below the specified requirements; and

(4) a retest consists of two additional specimens taken as near as practicable to the failed specimens. For acceptance of the retests, both specimens shall be meet the minimum requirements.

(b) For Charpy V-notch tests required by NF-2331 to meet the acceptance standards of Table NF-2331(a)-4, one retest at the same temperature may be conducted provided:

- (1) the average value of the test results meets the "Average of 3" requirements specified;
- (2) not more than one specimen per test is below the "Lowest 1 of 3" requirements specified;
- (3) the specimen not meeting the requirements is not lower than 5 ft-lb (6.8 J) below the "Lowest 1 of 3" requirements specified; and
- (4) a retest consists of two additional specimens taken as near as practicable to the failed specimens. For acceptance of the retests, both specimens shall be

Page 29

equal to or greater than the "Average of 3" requirements specified.

NF-2352 Retests for Bolting for Charpy V-Notch Tests

For Charpy V-notch tests of bolting required by NF-2333 to meet the acceptance standards of Table NF-2333-1, one retest at the same temperature may be conducted, provided:

- (a) the average value of the test results meets the minimum requirements;
- (b) not more than one specimen per test is below the minimum requirements;
- (c) the specimens not meeting the minimum requirements are not lower than 5 mils (0.13 mm) below the specified requirements; and
- (d) a retest consists of two additional specimens taken as near as practicable to the failed specimens. For acceptance of the retests, both specimens shall meet the minimum requirements.

NF-2360 CALIBRATION OF INSTRUMENTS AND EQUIPMENT

Calibration of temperature instruments and C_v impact test machines used in impact testing shall be performed at the frequency specified in (a) or (b) below.

(a) Temperature instruments used to control test temperature of specimens shall be calibrated and the results recorded to meet the requirements of NCA-3868 at least once in each 3 month interval.

(b) C_v impact test machines shall be calibrated and the results recorded to meet the requirements of NCA-3858.2. The calibrations shall be performed at least once in each 1 year interval using methods outlined in ASTM E 23-72 and employing standard specimens obtained from the National Institute of Standards and Technology.

NF-2400 WELDING MATERIAL

NF-2410 GENERAL REQUIREMENTS

(a) All welding material used in the construction and repair of supports or material, except welding material used for cladding or hard surfacing, shall conform to the requirements of the welding material specification or to the requirements for other welding material as permitted in Section IX. In addition, welding material shall conform to the requirements stated in this Subarticle and to the rules covering identification in NF-2150.

(b) The Certificate Holder shall provide the organization performing the testing with the information listed below, as applicable:

- (1) welding process;
- (2) SFA Specification and classification;
- (3) other identification if no SFA Specification applies;
- (4) minimum tensile strength [NF-2431.1(e)] in either the as-welded or heat treated condition, or both [NF-2431.1(c)];
- (5) Charpy V-notch test for material as-welded or heat treated, or both (NF-2331); the test temperature, and the lateral expansion or the absorbed energy, shall be provided;
- (6) the preheat and interpass temperatures to be used during welding of the test coupon [NF-2431.1(c)];
- (7) postweld heat treatment time, temperature range, and maximum cooling rate, if the production weld will be heat treated [NF-2431.1(c)];
- (8) elements for which chemical analysis is required per the SFA Specification or WPS, and NF-2432;
- (9) minimum delta ferrite (NF-2433).

NF-2420 REQUIRED TESTS

The required tests shall be conducted for each lot of covered, flux cored, or fabricated electrodes; for each heat of bare electrodes, rod, or wire for use with the OFW, GMAW, GTAW, PAW, and EGW (electro-gas welding) processes (Section IX, QW-492); for each heat of consumable inserts; for each combination of heat of bare electrodes and lot of submerged arc flux; for each combination of lot of fabricated electrodes and lot of submerged arc flux; for each combination of heat of bare electrodes or lot of fabricated electrodes and dry blend of supplementary powdered filler metal and lot of submerged arc flux; or for each combination of heat of bare electrodes and lot of electrosag flux. Tests performed on welding material in the qualification of weld procedures will satisfy the testing requirements for the lot, heat, or combination of heat and batch of welding material used, provided the tests required by NF-4000 and this Subarticle are made and the results conform to the requirements of this Article. The definitions in (a) through (h) below apply.

(a) A *dry batch of covering mixture* is defined as the quantity of dry covering ingredients mixed at one time in one mixing vessel; a dry batch may be used singly or may be subsequently subdivided into quantities

to which the liquid binders may be added to produce a number of wet mixes as in (c) below.

(b) A *dry blend* is defined as one or more dry batches mixed in a mixing vessel and combined proportionately to produce a uniformity of mixed ingredients equal to that obtained by mixing the same total amount of dry ingredients at one time in one mixing vessel.

(c) A *wet mix* is defined as the combination of a dry batch or dry blend [(a) and (b) above, respectively] and liquid binder ingredients at one time in one mixing vessel.

(d) A *lot of covered, flux-cored, or fabricated electrodes* is defined as the quantity of electrodes produced from the same combination of heat of metal and dry batch, dry blend, or chemically controlled mixes of flux or core materials. Alternatively, a lot of covered, flux-cored, or fabricated electrodes may be considered one type and size of electrode, produced in a continuous period, not to exceed 24 hr and not to exceed 100,000 lb (45,360 kg), from chemically controlled tube, wire, or strip and a dry batch, a dry blend, or chemically controlled mixes of flux, provided each container of welding materials is coded for identification and traceable to the production period, the shift, line, and analysis range of both the mix and the rod, tube, or strip used to make the electrode.

(1) *Chemically controlled tube, wire, or strip* is defined as consumable tube, wire, or strip material supplied on coils with maximum of one splice per coil that has been chemically analyzed to assure that the material conforms to the electrode manufacturer's chemical control limits for the specific type of electrode. Both ends of each coil shall be chemically analyzed except that those coils which are splice free need only be analyzed on one end of the coil.

(2) *Chemically controlled mixes of flux* are defined as flux material that has been chemically analyzed to assure that it conforms to the percent allowable variation from the electrode manufacturer's standard for each chemical element for that type electrode. A chemical analysis shall be made on each mix made in an individual mixing vessel after blending.

(e) A *heat of bare electrode, rod, wire, or consumable insert* is defined as the material produced from the same melt of metal.

(f) Alternatively, for carbon and low alloy steel bare electrode, rod, wire, or consumable inserts for use with SAW, OFW, GMAW, GTAW, PAW, and EGW processes, a *heat* may be defined as either the material produced from the same melt of metal or the material produced from one type and size of wire when produced in a continuous period, not to exceed 24 hr and not to exceed 100,000 lb (45,360 kg), from chemically controlled wire, subject to requirements of (1), (2), and (3) below.

(1) For the chemical control of the product of the rod mill, coils shall be limited to a maximum of one splice prior to processing the wire. Chemical analysis shall be made from a sample taken from both ends of each coil of mill coiled rod furnished by mills permitting spliced coil practice of one splice maximum per coil. A chemical analysis need be taken from only one end of rod coils furnished by mills prohibiting spliced coil practice.

(2) Carbon, manganese, silicon, and other intentionally added elements shall be determined to identify the material to ensure that it conforms to the SFA or user's material specification.

(3) Each container of wire shall be coded for identification and traceability to the lot, production period, shift, line, and analysis of rod used to make the wire.

(g) A *lot of submerged arc or electroslag flux* is defined as the quantity of flux produced from the same combination of raw materials under one production schedule.

(h) A *dry blend of supplementary powdered filler metal* is defined as one or more mixes of material produced in a continuous period, not to exceed 24 hr and not to exceed 20,000 lb (9070 kg) from chemically controlled mixes of powdered filler metal, provided each container of powdered metal is coded for identification and traceable to the production period, the shift, and the mixing vessel. A *chemically controlled mix of powdered filler metal* is defined as powdered filler metal material that has been chemically analyzed to assure that it conforms to the percent allowable variation from the powdered filler metal manufacturer's standard, for each chemical element, for that type of powdered filler metal. A chemical analysis shall be made on each mix made in an individual mixing vessel after blending. The chemical analysis range of the supplemental powdered filler shall be the same as that of the welding electrode, and the ratio of powder to electrode used to make the test coupon shall be the maximum permitted for production welding.

NF-2430 WELD METAL TESTS

NF-2431 Mechanical Properties Test

Tensile and impact tests shall be made, in accordance with this paragraph, of welding materials which are used to join P-Nos. 1, 3, 4, 5, 6, 7, 9, and 11 base materials in any combination, with the exceptions listed in (a) through (d) below:

Page 31

- (a) austenitic stainless steel and nonferrous welding material used to join the listed P-Numbers;
- (b) consumable inserts (backing filler material);
- (c) welding material used for GTAW root deposits with a maximum of two layers;
- (d) welding material to be used for the welding of base materials exempted from impact testing by NF-2311(b)(1) through (8) and NF-2311(b)(11) and (12) shall likewise be exempted from the impact testing required by this paragraph.

NF-2431.1 General Test Requirements.

The welding test coupon shall be made in accordance with (a) through (f) below using each process with which the weld material will be used in production welding.

- (a) Test coupons shall be of sufficient size and thickness that the test specimens required herein can be removed.
- (b) The weld metal to be tested for all processes except electroslag welding shall be deposited in such a manner as to eliminate substantially the influence of the base material on the results of the tests. Weld metal to be used with the electroslag process shall be deposited in such a manner as to conform to one of the applicable Welding Procedure Specifications (WPS) for production welding, Section IX, QW-201.1. The base material shall conform with the requirements of Section IX, QW-403.1 or QW-403.4, as applicable.

5 Any postweld heat treatment time which is anticipated to be applied to the material or item after it is completed shall be specified in the Design Specification. The Certificate Holder shall include this time in the total time at temperature specified to be applied to the test specimens.

- (c) The welding of the test coupon shall be performed within the range of preheat and interpass temperatures which will be used in production welding. Coupons shall be tested in the as-welded condition or they shall be tested in the applicable postweld heat treated condition when the production welds are to be postweld heat treated. The postweld heat treatment holding time⁵ shall be at least 80% of the maximum time to be applied to the weld metal in production application. The total time for postweld heat treatment of the test coupon may be applied in one heating cycle. The cooling rate from the postweld heat treatment temperature shall be of the same order as that applicable to the weld metal in the support. In addition, weld coupons for weld metal to be used with the electroslag process that are tested in the as-welded condition, or following a postweld heat treatment within the holding temperature ranges of Tables NF-4622.1-1 or NF-4622.4(c)-1, shall have a thickness within the range of 0.5 to 1.1 times the thickness of the welds to be made in production. Electroslag weld coupons to be tested following a postweld heat treatment, which will include heating the coupon to a temperature above the "Holding Temperature Range" of Table NF-4622.1-1 for the type of material being tested, shall have a thickness within the range of 0.9 to 1.1 times the thickness of the welds to be made in production.

- (d) Regardless of the welding process or welding material being tested, the tensile specimens, and the C_v impact specimens where required, shall be located and prepared in accordance with the requirements of SFA-5.1, Specification for Mild Steel Covered Electrodes. For impact specimen preparation and testing, the applicable parts of NF-2321 shall apply. The longitudinal axis of the specimen shall be at a minimum depth of $\frac{1}{4}t$ from a surface, where t is the thickness of the test weld.

- (e) One all weld metal tensile specimen shall be tested and shall meet the specified minimum tensile strength requirements of the base material specification. When base materials of different specifications are to be welded, the tensile strength requirements shall conform to the specified minimum tensile strength requirements of either of the base material specifications.

- (f) Impact specimens of the weld metal shall be tested where impact tests are required for either of the base materials of the production weld. The weld metal shall conform to the requirements of NF-2331(a), applicable to the base material.

Where different requirements exist for the two base materials, the weld metal may conform to either of the two requirements.

NF-2431.2 Standard Test Requirements.

In lieu of the use of the General Test Requirements specified in NF-2431.1, tensile and impact tests may be made in accordance with this subparagraph where they are required for mild and low alloy steel covered electrodes; the material combinations to require weld material testing, as listed in NF-2431, shall apply for this Standard Test Requirements option. The limitations and testing under this Standard Test option shall be in accordance with (a) through (f) below.

(a) Testing to the requirements of this subparagraph shall be limited to electrode classifications included in specifications SFA-5.1 or SFA-5.5.

(b) The test assembly required by SFA-5.1 or SFA-5.5, as applicable, shall be used for test coupon preparation, except that it shall be increased in size to obtain the number of C_v specimens required by NF-2331(a), where applicable.

(c) The welding of the test coupon shall conform to the requirements of the SFA Specification for the classification of electrode being tested. Coupons shall

Page 32

be tested in the as-welded condition and also in the postweld heat treated condition. The postweld heat treatment temperatures shall be in accordance with Table NF-4622.1-1 for the applicable P-Number equivalent. The time at postweld heat treatment temperature shall be 8 hr (this qualifies postweld heat treatments of 10 hr or less). When the postweld heat treatment of the production weld exceeds 10 hr, or the PWHT temperature is other than that required above, the general test of NF-2431.1 shall be used.

**TABLE NF-2432.1-1

A-No. 8 filler metal	Filler metal or weld deposit	Weld deposit	Weld deposit
All other filler metal	Filler metal or weld deposit	Filler metal or weld deposit	Weld deposit

TABLE NF-2432.1-1 SAMPLING OF WELDING MATERIALS FOR CHEMICAL ANALYSIS

(d) The tensile and C_v specimens shall be located and prepared in accordance with the requirements of SFA-5.1 or SFA-5.5, as applicable.

(e) One all weld metal tensile specimen shall be tested and shall meet the specified minimum tensile strength requirement of the SFA Specification for the applicable electrode classification.

(f) The requirements of NF-2431.1(f) shall be applicable to the impact testing of this option.

NF-2432 Chemical Analysis Test

Chemical analysis of filler metal or weld deposits shall be made in accordance with NF-2420 and as required by the following subparagraphs.

NF-2432.1 Test Method.

The chemical analysis test shall be performed in accordance with this Subparagraph and Table NF-2432.1-1, and the results shall conform to NF-2432.2.

(a) A-No. 8 welding material to be used with GTAW and PAW processes and any other welding material to be used with any GTAW, PAW, or GMAW process shall have chemical analysis performed either on the filler metal or on a weld deposit made with the filler metal in accordance with (c) or (d) below.

(b) A-No. 8 welding material to be used with other than the GTAW and PAW processes and other welding material to be used with other than the GTAW, PAW, or GMAW process shall have chemical analysis performed on a weld deposit of the material or combination of materials being certified in accordance with (c) or (d) below. The removal of chemical analysis samples shall be from an undiluted weld deposit made in accordance with (c) below. As an alternative, the deposit shall be made in accordance with (d) below for material that will be used for corrosion resistant overlay cladding. Where the Welding Procedure Specification or the welding material specification specifies percentage composition limits for analysis, it shall state that the specified limits apply for either the filler metal analysis or the undiluted weld deposit analysis or for *in situ* cladding deposit analysis in conformance with the above required certification testing.

(c) The preparation of samples for chemical analysis of undiluted weld deposits shall comply with the method given in the applicable SFA Specification. Where a weld deposit method is not provided by the SFA Specification, the sample shall be removed from a weld pad, groove, or other test weld⁶ made using the welding process that will be followed when the welding material or combination of welding materials being certified is consumed. The weld for A-No. 8 material to be used with the GMAW or EGW process shall be made using the shielding gas composition specified in the Welding Procedure Specification that will be followed when the material is consumed. The test sample for ESW shall be removed from the weld metal of the mechanical properties test coupon. Where a chemical analysis is required for a welding material which does not have a mechanical properties test requirement, a chemical analysis test coupon shall be prepared as required by NF-2431.1(c), except that heat treatment of the coupon is not required and the weld coupon thickness requirements of NF-2431.1(c) do not apply.

⁶ The methods given in the Appendix of SFA 5.9, Specification for Corrosion-Resisting Chromium and Chromium-Nickel Steel Welding Rods and Bare Electrodes, shall be used to establish a welding and sampling method for the pad, groove, or other test weld to ensure that the weld deposit being sampled will be substantially free of base metal dilution.

(d) The alternate method provided in (b) above for the preparation of samples for chemical analysis of welding material to be used for corrosion resistant overlay cladding shall require a test weld made in accordance with the essential variables of the Welding Procedure Specification that will be followed when the welding material is consumed. The test weld shall be made in conformance with the requirements of Section IX, QW-214.1. The removal of chemical analysis samples shall conform with QW-214.3 for the minimum

thickness for which the Welding Procedure Specification is qualified.

TABLE NF-2432.2(a)-1 WELDING MATERIAL CHEMICAL ANALYSIS

Cr–Ni stainless materials	C, Cr, Mo, Ni, Mn, Si, Cb
---------------------------	------------------------------

TABLE NF-2432.2(a)-1 WELDING MATERIAL CHEMICAL ANALYSIS

NF-2432.2 Requirements for Chemical Analysis.

The chemical elements to be determined, the composition requirements of the weld metal, and the recording of results of the chemical analysis shall be in accordance with (a), (b), and (c) below.

(a) Welding material of ferrous alloy A-No. 8 (Section IX, QW-442) shall be analyzed for the elements listed in Table NF-2432.2(a)-1 and for any other elements specified either in the welding material specification referenced by the Welding Procedure Specification or in the Welding Procedure Specification.

(b) The chemical composition of the weld metal or filler metal shall conform to the welding material specification for elements having specified percentage composition limits. Where the Welding Procedure Specification contains a modification of the composition limits of SFA or other referenced welding material specifications, or provides limits for additional elements, these composition limits of the Welding Procedure Specification shall apply for acceptability.

(c) The results of the chemical analysis shall be reported in accordance with NCA-3862.1. Elements listed in Table NF-2432.2(a)-1 but not specified in the welding material specification or Welding Procedure Specification shall be reported for information only.

NF-2433 Delta Ferrite Determination

A determination of delta ferrite shall be performed on A-No. 8 weld material (Section IX, QW-442) backing filler metal (consumable inserts); bare electrode, rod, or wire filler metal; or weld metal, except that delta ferrite determinations are not required for SFA-5.4, Type 16-8-2, or A-No. 8 weld filler metal to be used for weld metal cladding.

NF-2433.1 Method.

Delta ferrite determinations of welding material, including consumable insert material, shall be made using a magnetic measuring instrument and weld deposits made in accordance with (b) below. Alternatively, the delta ferrite determinations for welding materials may be performed by the use of chemical analysis of NF-2432 in conjunction with Fig. NF-2433.1-1.

(a) Calibration of magnetic instruments shall conform to AWS A4.2-91.

(b) The weld deposit for magnetic delta ferrite determination shall be made in accordance with NF-2432.1(c).

(c) A minimum of six ferrite readings shall be taken on the surface of the weld deposit. The readings obtained shall be averaged to a single Ferrite Number (FN).

NF-2433.2 Acceptance Standards.

The minimum acceptable delta ferrite shall be 5FN. The results of the delta ferrite determination shall be included in the Certified Material Test Report of NF-2130 or NF-4120.

NF-2440 STORAGE AND HANDLING OF WELDING MATERIAL

Suitable storage and handling of electrodes, flux, and other welding materials shall be maintained. Precautions shall be taken to minimize absorption of moisture by fluxes and cored, fabricated, and coated electrodes.

NF-2500 EXAMINATION AND REPAIR OF MATERIAL

NF-2510 EXAMINATION AND REPAIR OF MATERIAL OTHER THAN BOLTING

Material for supports shall be examined in accordance with the material specification. Defects may be repaired as permitted by the material specification.

NF-2580 EXAMINATION OF BOLTING MATERIAL AND RODS⁷

NF-2581 Required Examinations

NF-2581.1 Class 1 Supports.

All bolting material and rods shall be visually examined in accordance with NF-2582. Nominal sizes greater than 2 in. shall be examined by either the magnetic particle or liquid penetrant method (NF-2583). In addition, nominal sizes greater than 4 in. shall be ultrasonically examined as required by NF-2584.

⁷ The word rods as used in this Subarticle is intended to cover rods that are threaded. It also includes forged piston rods if they are threaded for a portion of their length. It does not apply to unthreaded bar stock.

GENERAL NOTES:

- (a) The actual nitrogen content is preferred. If this is not available, the following applicable nitrogen value shall be used:
 - (1) GMAW welds - 0.08%, except that when self shielding flux cored electrodes are used - 0.12%.
 - (2) Welds made using other processes - 0.06%.
- (b) This diagram is identical to the WRC-1992 Diagram, except that the solidification mode lines have been removed for ease of use.

FIG. NF-2433.1-1 DELTA FERRITE CONTENT

FIG. NF-2433.1-1 DELTA FERRITE CONTENT

NF-2581.2 Class 2, 3, and MC Supports.

Bolts, studs, and nuts shall be examined in accordance with the requirements of the material specification and NF-2582

NF-2582 Visual Examination

The areas of threads, shanks, and heads of final machined parts shall be visually examined. Harmful discontinuities such as laps, seams, or cracks that would be detrimental to the intended service are unacceptable.

NF-2583 Magnetic Particle or Liquid Penetrant Examination

All bolting material and rods greater than 2 in. (51 mm) nominal size for Class 1 supports shall be examined by a magnetic particle method or a liquid penetrant method. Such examination shall be performed on the finished bolting material after threading or on the material stock at approximately the finished diameter before threading and after heading (if involved). Linear nonaxial indications are unacceptable. Linear axial indications greater than 1 in. in length are unacceptable.

NF-2584 Ultrasonic Examination for Sizes Greater Than 4 in. (102 mm)

All bolting material and rods greater than 4 in. (102 mm) nominal size for Class 1 supports shall be ultrasonically examined over the entire surface prior to threading in accordance with the requirements of the following subparagraphs.

NF-2584.1 Ultrasonic Method.

Examination shall be carried out by the straight beam, radial scan method.

NF-2584.2 Examination Procedure.

Examination shall be performed at a nominal frequency of 2.25 MHz with a search unit not to exceed 1 sq in. (645 mm²) area.

NF-2584.3 Calibration of Equipment.

Calibration sensitivity shall be established by adjustment of the instrument so that the first back reflection is 75%-90% of full screen height.

NF-2584.4 Acceptance Standards.

Any discontinuity which causes an indication in excess of 20% of the height of the first back reflection or any discontinuity which prevents the production of a first back reflection of 50% of the calibration amplitude is not acceptable.

NF-2586 Repair by Welding

Weld repairs of bolting material and rods are not permitted.

NF-2600 MATERIAL MANUFACTURER'S QUALITY SYSTEM PROGRAMS

NF-2610 DOCUMENTATION AND MAINTENANCE OF QUALITY SYSTEM PROGRAMS

(a) Except as provided in (b) below, Material Organizations shall have a Quality System Program or an Identification and Verification Program, as applicable, which meets the requirements of NCA-3800.

(b) The requirements of NCA-3862 shall be met as required by NF-2130. The other requirements of NCA-3800 need not be used by Material Organizations for small products, as defined in (c) below, for brazing material, and for material which is allowed by this Subsection to be furnished with a Certificate of Compliance. For these products, the Certificate Holder's Quality Assurance Program (NCA-4000) shall include measures to provide assurance that the material is furnished in accordance with the material specification and the requirements of this Subsection.

(c) For the purpose of this paragraph, small products are defined as given in (1) through (3) below:

- (1) pipe, tube, pipe fittings, and flanges of 2 in. (51 mm) nominal size and less;
- (2) bolting material, including studs, nuts, and bolts of 2 in. (51 mm) nominal diameter and less;
- (3) structural material with a nominal cross-sectional area of 2 sq in. (1290 mm²) and less.
- (d) When impact testing is required in accordance with NF-2300, the material not exempted by NF-2311 shall be furnished with Certified Material Test Reports in accordance with NCA-3862.
- (e) Structural materials, which are permitted by this Section to be furnished with a Certificate of Compliance, may be repaired by welding using welders, documentation, and examination requirements specified in SA-6 and need not meet the requirements of NCA-3857.3.
- (f) Materials manufactured to a Material Specification prohibiting weld repair without user approval do not require documentation to indicate that weld repairs have not been performed.

SEC III D1 NF-3000

ARTICLE NF-3000 DESIGN

Page 37

NF-3100 GENERAL DESIGN REQUIREMENTS

NF-3110 LOADING CRITERIA

NF-3111 Loading Conditions

The loadings that shall be taken into account in designing a support include, but are not limited to, those in (a) through (h) below:

- (a) weight of the piping or component and normal contents under plant and system operating and test conditions, including loads due to static and dynamic head and fluid flow effects;
- (b) weight of the support;
- (c) superimposed static and thermal loads and reactions induced by the supported system components;
- (d) dynamic loads, including loads caused by earthquake and vibration;
- (e) effects from piping thermal expansion;
- (f) anchor and support movement effects;
- (g) environmental loads such as wind and snow loads;
- (h) expansion or contraction of a component produced by internal or external pressure.

Guidelines for classification of these loadings into primary, secondary, or peak are listed in NF-3120 and NF-3220.

NF-3112 Design Loadings

The Design Loadings shall be established in accordance with NCA-2142.1 and the following subparagraphs.

[98]

NF-3112.1 Design Temperature.

The specified Design Temperature shall be established in accordance with NCA-2142.1(b). The metal temperature shall be determined by computation using accepted heat transfer procedures or by measurement from equipment in service under plant and system equivalent operating conditions. In lieu of heat transfer analysis or measurements, the component or piping Design Temperature may be used. In no case shall the temperature at the surface of the metal exceed the maximum temperature listed in Tables 1A, 1B, 2A, 2B, 3, 4, and Y-1 of Section II, Part D, Subpart 1, or exceed the maximum temperature limitations specified elsewhere in this Subsection.

[98]

NF-3112.2 Design Mechanical Loads.

The specified Design Mechanical Loads shall be established in accordance with NCA-2142.1(c), and shall include all loads from the component or piping acting on the support.

NF-3112.3 Design Stress Intensity and Allowable Stress Values.

When the procedures of design by analysis (NF-3220) are employed, the applicable design stress intensity values S_m listed in Tables 2A, 2B, and 4 of Section II, Part D, Subpart 1 shall be used. When the procedures of linear elastic analysis (NF-3320) are employed, the allowable stress values shall be the applicable yield strength values S_y listed in Table Y-1, Section II, Part D, Subpart 1 as modified by the design factors given in NF-3322.

NF-3113 Service Conditions

Each Service Condition to which the piping or component may be subjected shall be categorized in accordance with NCA-2142.2, and Service Limits [NCA-2142.4(b)] shall be designated in the Design Specification in such detail as will provide a complete basis for design in accordance with this Article.

NF-3114 Test Conditions

The component and piping support loadings resulting from test conditions shall be identified (NCA-2142).

NF-3120 DESIGN CONSIDERATIONS

NF-3121 Terms Relating to Design by Analysis

NF-3121.1 General Considerations

(a) Terms that are common to the design by stress analysis of Plate- and Shell-Type, Linear-Type, and

Page 44

Standard Supports are defined in NF-3121.2 through NF-3121.16 below.

(b) Terms unique to the design by stress analysis of Plate- and Shell-Type Supports are defined in NF-3212.

(c) Terms unique to the design by stress analysis of Linear-Type Supports are defined in NF-3313.

NF-3121.2 Primary Stress.

Primary stress is any normal stress or shear stress developed by an imposed loading which is necessary to satisfy the laws of equilibrium of external and internal forces and moments. The basic characteristic of a primary stress is that it is not self-limiting. Primary stresses which considerably exceed the yield strength S_y will result in failure or, at least, in gross distortion. A thermal stress is not classified as a primary stress. A general primary membrane stress is one which is so distributed in the support that no redistribution of load occurs in the support as a result of yielding. Examples of primary stress are general membrane stress in a circular cylindrical shell due to a uniformly distributed axial load, and bending stress in a cantilever beam due to a normal end load. In addition to the above, for supports, stresses induced in the support by restraint of free end displacement [NF-3111(e)] and anchor motion [NF-3111(f)] of piping are considered primary stresses.

NF-3121.3 Secondary Stress.

Secondary stress is a normal stress or a shear stress developed by the constraint of adjacent material or by self-constraint of the structure. The basic characteristic of a secondary stress is that it is self-limiting. Local yielding and minor distortions can satisfy the conditions which cause the stress to occur, and failure from one application of the stress is not to be expected. An example of secondary stress is bending stress at a gross structural discontinuity.

NF-3121.4 Peak Stress.

Peak stress is that increment of stress which is additive to the primary plus secondary stresses by reason of local discontinuities or local thermal stress, including the effects, if any, of stress concentrations. The basic characteristic of a peak stress is that it does not cause any noticeable distortion and is objectionable only as a possible source of a fatigue crack or brittle fracture. A stress which is not highly localized falls into this category if it is of a type which cannot cause noticeable distortion. Evaluation of peak stresses in the support is not required by this Subsection.

NF-3121.5 Normal Stress.

Normal stress is the component of stress normal to the plane of reference. This is also referred to as direct stress. Usually the distribution of normal stress is not uniform through the thickness of a part, so this stress is considered to be made up in turn of two components, one uniformly distributed and equal to the average value of stress across the thickness under consideration, and the other varying from this average value with the location across the thickness.

NF-3121.6 Shear Stress.

Shear stress is the component of stress tangent to the plane of reference.

NF-3121.7 Membrane Stress.

Membrane stress is the component of normal stress which is uniformly distributed and equal to the average of stress across the thickness of the section under consideration.

NF-3121.8 Bending Stress.

Bending stress is the variable component of normal stress. The variation may or may not be linear across the thickness.

NF-3121.9 Total Stress.

Total stress is the sum of the primary and secondary stress contributions. Recognition of each of the individual contributions is essential to establishment of appropriate stress limitations.

NF-3121.10 Critical Buckling.

Critical buckling occurs when a support is loaded to a state at which an infinitesimal additional load or disturbance causes the support to change from an equilibrium condition to one of instability.

NF-3121.11 Thermal Stress.

Thermal stress is a self-equilibrating stress produced by a nonuniform distribution of temperature or by differing thermal coefficients of expansion. Thermal stress is developed in a solid body whenever a volume of material is prevented from assuming the size and shape that it normally would under a change in temperature. Evaluation of thermal stresses in the support is not required by this Subsection.

NF-3121.12 Free End Displacement.

Free end displacement consists of the relative motions that would occur between an attachment and connected structure or equipment if the two members were separated and permitted to move.

NF-3121.13 Anchor Point Motion Stress.

Anchor point motion stresses are those stresses resulting from the differential motion of support points. An example is differential building settlement.

NF-3121.14 Gross Structural Discontinuity.

Gross structural discontinuity is a geometric or material discontinuity which affects the stress or strain distribution through the entire thickness of the member. Gross discontinuity-type stresses are those portions of the actual stress distributions that produce net bending and membrane force resultants when integrated through the thickness. Examples of gross structural discontinuities

Page 45

are junctions between parts of different diameters or thicknesses and flange-to-shell junctions.

NF-3121.15 Limit Analysis - Collapse Load.

The methods of limit analysis are used to compute the maximum load or combination of loads a structure made of ideally plastic (nonstrain-hardening) material can carry. The deformations of an ideally plastic structure increase without bound at this load, which is termed the collapse load.

NF-3121.16 Collapse Load - Lower Bound.

If, for a given load, any system of stresses can be found which everywhere satisfies equilibrium and nowhere exceeds the material yield strength, using shape factors associated with the cross section under consideration, the load is at or below the collapse load. This is the lower bound theorem of limit analysis which permits calculations of a lower bound to the collapse load.

NF-3122 Piping or Component Deformation Limits

Deformation limits for the supported piping or component shall be stipulated in the Design Specifications, if required.

NF-3123 Functional Requirements

When a support is to be designed to perform a specific function during any Service Condition, the functional requirements shall be designated in the Design Specifications.

NF-3124 Rolling and Sliding Supports

(a) Rolling and sliding supports shall permit free movement of the piping or component, or the piping or component shall be designed to include the imposed load and frictional resistance of these types of supports; their dimensions shall provide for the designed movement of the supported piping or component.

(b) Sliding supports (or shoes) and brackets shall be designed to accommodate the forces caused by friction in addition to the loads imposed by bearing. The dimensions of the support shall provide for the design movement of the supported piping or component. Material and lubricants used in sliding supports shall be suitable for the environment of the metal at the point of sliding contact and shall be specified in the Design Documents.

NF-3125 Sway Braces and Vibration Dampeners

Sway braces and vibration dampeners may be used to limit the effects of vibration and may be of the rigid strut (linear type) tension-compression type. If employed in the design or added as a result of observation under startup or initial operating conditions, the effect of sway braces shall be included in the stress analysis of the piping or component for all of the specified conditions.

NF-3127 Provisions for Movement of Supported Piping or Component

Consideration shall be given to the relative motion of the supported piping or component and the support. When clearances or travel ranges or both are required to accommodate piping or component movements, sufficient design margins shall be introduced to allow for variations due to fabrication and installation. Care shall be taken to ensure that design clearances and travel ranges are based on the maximum range that might occur between two operating conditions

and not necessarily on the maximum cold to hot range. All parts of the support shall be fabricated and assembled so that they will not be disengaged by movement of the supported piping or component. Supports needed only to provide stability during Level C or Level D Service Conditions shall be designed and installed so as not to overstress the piping or component during Level A or Level B Service Conditions.

NF-3128 Snubbers

The end connection of the snubber shall be designed to accommodate vertical and horizontal movement of the piping or component, as required.

NF-3130 GENERAL DESIGN REQUIREMENTS

NF-3131 Requirements for Acceptability

The requirements for acceptability of support design are given in (a) through (e) below.

(a) The design shall be such that the stress intensity values or the stress values (whichever are applicable) will not exceed the limits given in this Subarticle. Table NF-3131(a)-1 indicates the rules and limits to be used for the various classes and types of design procedures. The applicable tables of allowable stress

Page 46

values for materials to be used with a specific design procedure are referenced in Table NF-2121(a)-1.

TABLE NF-3131(a)-1 REFERENCE PARAGRAPHS FOR PROCEDURES FOR DESIGN OF COMPONENT SUPPORTS, PIPING SUPPORTS, AND STANDARD SUPPORTS

- (b) The design procedure shall be one of those given in Table NF-3131(a)-1 as being applicable to supports.
- (c) The design details shall conform to the rules of this Subarticle or to those referenced herein.
- (d) For configurations where compressive stresses occur, the critical buckling stress shall be taken into account in addition to the requirements of (a), (b), and (c) above.
- (e) For Class 1 supports, protection against nonductile fracture shall be provided. An acceptable procedure for nonductile failure prevention is given in Appendix G of Section III, Division 1, Appendices.

[98]

NF-3132 Dimensional Standards

Dimensions of component and piping supports may comply with the standards and specifications listed in Table NF-3132-1 but are not mandatory. Compliance

Page 47

with these standards does not replace or eliminate the requirements for stress analysis or load rating. Guidance on tolerances for supports is provided in Appendix K of Section III, Division 1, Appendices.

TABLE NF-3132-1 DIMENSIONAL STANDARDS

NF-3133 Stress Analysis

A detailed stress analysis or Design Report, as required by NCA-3550 for all supports, shall be prepared in sufficient detail to show that each of the stress limits of NF-3200 or NF-3300 is satisfied when the piping or component support is subjected to the loadings of NF-3110.

NF-3140 GENERAL DESIGN PROCEDURES

NF-3141 Types of Procedures

(a) The design procedure which may be used is dependent on the type of support being designed and the Class of construction involved. Three design procedures are recognized, namely:

(1) design by analysis:

(a) maximum shear stress theory

(b) maximum stress theory

(2) experimental stress analysis (Section III, Division 1, Appendices, Appendix II)

(3) load rating

(b) Unless either the experimental stress analysis procedure or the load rating procedure is used, the requirements of the following paragraphs apply.

NF-3142 Plate- and Shell-Type Supports - Analysis Procedure

(a) Elastic analysis based on maximum shear stress theory in accordance with the rules of NF-3200 shall be used in the design of Plate- and Shell-Type Supports of Class 1 construction.

(b) Elastic analysis based on maximum stress theory shall be used in the design of Plate- and Shell-Type Supports of Class 2, 3, and MC construction. Supports for Class 2 vessels designed to NC-3200 shall be designed in accordance with Class 1 requirements.

NF-3143 Linear-Type Supports - Analysis Procedure

(a) The analysis procedure shall comply with (1) or (2) below.

(1) Elastic analysis based on maximum stress theory in accordance with the rules of NF-3300 shall be used for the design of Linear-Type Supports for Class 1, 2, 3, and MC construction.

(2) Limit analysis in accordance with the procedures of NF-3340 shall be used in the design of Linear-Type

Page 48

Supports for Class 1, 2, 3, and MC construction when members and their connections are subject to high cycle fatigue as defined in NF-3331.

(b) High cycle fatigue analysis in accordance with procedures of NF-3330 shall be used in the design of Linear-Type Supports for Class 1 construction.

NF-3144 Standard Supports - Analysis Procedure

Standard Supports designed by analysis shall be designed to either the requirements of NF-3142 or NF-3143, according to whether they are Plate- and Shell-Type or Linear-Type Standard Supports.

NF-3200 DESIGN RULES FOR PLATE- AND SHELL-TYPE SUPPORTS

NF-3210 GENERAL REQUIREMENTS

NF-3211 Basis for Determining Stresses in Design by Analysis

The theory of failure used in the rules of this Subsection for combining stresses for the design of Class 1 Plate- and Shell-Type Supports is the maximum shear stress theory; for Class 2, 3, and MC Plate- and Shell-Type Supports, it is the maximum stress theory.

NF-3212 Definitions

Terms used in the design of Plate- and Shell-Type Supports by stress analysis are defined in NF-3121 and in NF-3212.1 below.

NF-3212.1 Stress Intensity.¹

Stress intensity is defined as twice the maximum shear stress. The stress intensity is the difference between the algebraically largest principal stress and the algebraically smallest principal stress at a given point. Tensile stresses are considered positive and compressive stresses are considered negative.

NF-3220 DESIGN BY ANALYSIS FOR CLASS 1

¹ This definition of stress intensity is not related to the definition of stress intensity applied in the field of fracture mechanics.

NF-3221 Stress Limits

Stress limits for elements of Class 1 supports are given in this paragraph. Stress limits for bolts and welds are given in NF-3225 and NF-3226. General requirements concerning stress determinations, definitions, derivations of stress intensities, and classification of stresses are given in NF-3210.

Plate- and Shell-Type Supports may be designed by either elastic or limit analysis, stress intensity limits for which are given in the following subparagraphs.

NF-3221.1 Design Limits.

The stress intensity limits which must be satisfied for the Design Loadings stated in the Design Specification are the two limits of this paragraph and the Special Stress Limits of NF-3223. The design stress intensity values S_m are given in NF-3224.

(a) General primary membrane stress intensity P_m is derived from the average value across the thickness of a section of the general primary stresses produced by specified Design Mechanical Loads, but excluding all secondary stresses. Averaging is to be applied to the stress components prior to determination of the stress intensity values. The allowable value of this stress intensity is S_m at the Design Temperature.

(b) Primary membrane plus primary bending stress intensity $P_m + P_b$ is derived from the highest value across the thickness of a section of the general membrane stresses plus primary bending stresses produced by the specified Design Mechanical Loads, but excluding all secondary stresses. The allowable value of this stress intensity is $1.5S_m$.

NF-3221.2 Service Level A Through D Service Limits.

The rules and stress limits which must be satisfied in an elastic analysis for any Level A through D Service Loadings stated in the Design Specification are those given in NF-3221.1 and NF-3223 multiplied by the appropriate stress intensity limit factor from Tables NF-3522(b)-1 and NF-3622(b)-1 for the particular loading and stress categories.

NF-3221.3 Test Limits.

The rules and stress limits which must be satisfied for any Test Loadings stated in the Design Specification are those given in NF-3221.1 and NF-3223 multiplied by the appropriate stress intensity limit factor in Tables NF-3522(b)-1 and NF-3622(b)-1 under Test Loadings.

NF-3221.4 Limit Analysis.

The limits on primary membrane plus primary bending stress intensity [NF-3221.1(b)] need not be satisfied at a specific location if it can be shown by means of limit analysis or by tests that the specified loadings do not exceed two-thirds of the lower bound collapse load for Design Loadings and Service Level A and B Loadings, and do not exceed 0.8 times the lower bound collapse load for Service Level C Loadings. The rules of Appendix F (Section III, Division 1, Appendices) shall apply for

Service Level D Loadings. For materials in Section II, Part D, Subpart 1 for which allowable stresses, or stress intensities, may reach 90% of the yield strength S_y at temperature, the specified loading shall not exceed the product of the applicable permanent strain limiting factor of Table Y-2, Section II, Part D, Subpart 1 times the lower bound collapse load.

NF-3222 Derivation of Stress Intensities

One requirement for the acceptability of a design (NF-3130) is that the calculated stress intensities shall not exceed specified allowable limits. These limits differ depending on the stress category (primary, secondary, etc.) from which the stress intensity is derived. This paragraph describes the procedure for the calculation of the stress intensities which are subject to the specified limits. The steps in the procedure are stipulated in (a) through (e) below.

(a) At the point on the support which is being investigated, choose an orthogonal set of coordinates, such as tangential, longitudinal, and radial, and designate them by the subscripts t , l , and r . The stress components in these directions are then designated σ_t , σ_l , and σ_r for direct stresses and T_{lt} , T_{lr} , and T_{rt} for shear stresses.

(b) Calculate the stress components for each type of loading to which the item will be subjected and assign each set of stress values to one or a group of the following categories:

(1) general primary membrane stress P_m (NF-3121.7)

(2) primary bending stress P_b (NF-3121.8)

(3) secondary stress Q (NF-3121.3)

(c) For each category, calculate the algebraic sum of the values of σ_t which result from the different types of loadings, and similarly for the other five stress components. Certain combinations of the categories must also be considered.

(d) Translate the stress components for the t , l , and r directions into principal stresses σ_1 , σ_2 , and σ_3 .

(e) Calculate the stress differences S_{12} , S_{23} , and S_{31} from the relations:

$$S_{12} = \sigma_1 - \sigma_2$$

$$S_{23} = \sigma_2 - \sigma_3$$

$$S_{31} = \sigma_3 - \sigma_1$$

The stress intensity S is the largest absolute value of S_{12} , S_{23} , and S_{31} .

NOTE: Membrane stress intensity is derived from the stress components averaged across the thickness of the section. The averaging shall be performed at the component stress level in step (b) or (c) above.

NF-3223 Special Stress Limits

The following deviations from the basic stress limits are provided to cover special Service Loadings or configurations. Some of these deviations are more restrictive and some are less restrictive than the basic stress limits. In cases of conflict between these requirements and the basic stress limits, the rules of this paragraph take precedence for the particular situations to which they apply.

NF-3223.1 Bearing Loads

(a) The average bearing stress for resistance to crushing under the maximum load, experienced as a result of Design Loadings, Test Loadings, or any Service Loadings, except those for which Level D Limits are designated, shall be limited to S_y at temperature, except that when the distance to a free edge is larger than the distance over which the bearing load is applied, a stress of $1.5S_y$ at temperature is permitted.

(b) When bearing loads are applied near free edges, such as at a protruding ledge, the possibility of a shear failure shall be considered. The average shear stress shall be limited to $0.6S_m$ in the case of primary stress (NF-3121.2) and $0.5S_y$ in the case of primary stress plus secondary stress (NF-3121.9).

(c) When considering bearing stresses in pins and similar members, the S_y at temperature is applicable, except that a value of $1.5S_y$ may be used if no credit is given to the bearing area within one pin diameter from a plate edge.

NF-3223.2 Pure Shear

(a) The average primary shear stress across a section loaded in pure shear, experienced as a result of Design Loadings, Test Loadings, or any Service Loadings, except those for which Level D Limits are designated, shall be limited to $0.6S_m$.

(b) The maximum primary shear, experienced as a result of Design Loadings, Test Loadings, or any Service Loadings except those for which Level D Limits are designated, exclusive of stress concentration at the periphery of a solid circular section in torsion, shall be limited to $0.8S_m$. Primary plus secondary shear stresses shall be converted to stress intensities (equal to two times pure shear stress) and as such shall not exceed the basic stress limits of Tables NF-3522(b)-1 and NF-3622(b)-1.

Page 50

NF-3223.3 Triaxial Stresses.

The algebraic sum of the three primary principal stresses ($\sigma_1 + \sigma_2 + \sigma_3$) shall not exceed four times the tabulated value of S_m .

NF-3223.4 Applications of Elastic Analysis for Stresses Beyond the Yield Strength.

Certain of the allowable stresses permitted in the design criteria are such that the maximum stress calculated on an elastic basis may exceed the yield strength of the material.

NF-3224 Design Stress Values

The design stress intensity values S_m are given in Tables 2A, 2B, and 4, Section II, Part D, Subpart 1 for support material. Values for intermediate temperatures may be found by interpolation. These form the basis for the various stress limits. Values of yield strength are given in Table Y-1, Section II, Part D, Subpart 1. S_m values for bolting materials listed in Table 4, Section II, Part D, Subpart 1 are based on $(1/3)S_y$. Multiply S_m by three to arrive at S_y values for the material (Round up to next higher 0.5 ksi). Values of the coefficient of thermal expansion and of the modulus of elasticity are given in Tables TE and TM, Section II, Part D, Subpart 2. The basis for establishing stress values is given in Appendix III (Section III, Division 1, Appendices).

NF-3225 Design of Bolting

NF-3225.1 Design Limits.

The rules and stress limits which must be satisfied for any Design Loading stated in the Design Specification are those given in NF-3324.6.

NF-3225.2 Service Limits, Level A Through D.

The rules and stress limits which must be satisfied for any Level A through D Service Loading stated in the Design Specification are those given in NF-3324.6 multiplied by the appropriate stress limit factor for the particular service loading level and stress category specified in Table NF-3225.2-1. This product shall not exceed the yield strength of the material at temperature.

NF-3225.3 Test Limits.

The rules and stress limits which must be satisfied for any Test Loadings stated in the Design Specification are those given in NF-3324.6 multiplied by the appropriate stress limit factor for the particular Service Loading Level and stress category specified in Table NF-3225.2-1.

NF-3225.4 Friction-Type Joints.

Multiplying factors normally used to increase the allowable limits for Service Level B, C, and D are not applicable to friction-type joints [see NF-3324.6(a)(4)].

NF-3226 Design of Welded Joints

NF-3226.1 Permissible Types of Welded Joints in Plate- and Shell-Type Supports.

All welded joints in Plate- and Shell-Type Supports shall be continuous and shall be of one of the types listed in (a) through (c) below. Typical examples of those permitted types are shown in Fig. NF-3226.1-1. Fillet and partial penetration welds shall meet the requirements of NF-3324.5(d), except that NF-3324.5(d)(7) does not apply.

(a) *Butt Joints.* Butt joints shall be one of the following:

- (1) full penetration, single or double welded [Fig. NF-3226.1-1, sketches (a-1) and (a-2)];
- (2) partial penetration, double welded [Fig. NF-3226.1-1, sketch (b)];
- (3) the applicable welds may be either square groove, V groove, bevel groove, J groove, U groove, flare V groove, or flare bevel groove [see Fig. NF-3226.1(a)-1];
- (4) when angle joints are used for connecting a transition in diameter to a cylinder, the angle α of Fig. NF-3226.1-1, sketch (f) shall not exceed 30 deg.
- (5) A tapered transition having a length not less than three times the offset between the adjacent surfaces of abutting sections, as shown in Fig. NF-3226.1(a)-2, shall be provided at joints between sections that differ in thickness by more than one-fourth of the thickness of the thinner section or by more than $\frac{1}{8}$ in. (3.2 mm), whichever is less. The transition may be formed by any process that will provide a uniform taper. The weld may be partly or entirely in the tapered section, or adjacent to it. This paragraph also applies when there is a reduction in thickness within a spherical shell, or cylindrical course or plate.
- (6) When the use of backing rings will result in undesirable conditions such as severe stress or corrosion, the requirements of NF-4240 shall be met.

(b) *Corner Joints.* Corner joints shall be one of the following:

- (1) full penetration, as shown in Fig. NF-3226.1-1, sketch (d-1);
- (2) partial penetration with a fillet weld as shown in Fig. NF-3226.1-1, sketches (d-2) and (d-3);
- (3) the applicable welds are fillet, square groove, V groove, bevel groove, U groove, J groove, flare V groove and flare bevel groove.

(c) *Tee Joints.* Tee joints shall be one of the following:

- (1) full penetration, Fig. NF-3226.1-1, sketches (c) and (g);
- (2) partial penetration, double welded with or without additional fillet welds, Fig. NF-3226.1-1, sketch (e);

**TABLE NF-3225.2-1
STRESS LIMIT FACTORS
FOR CLASS 1, 2, 3, AND MC BOLT DESIGN BY ANALYSIS**

Stress Category	Stress Limit Factors for Loading Levels Stated in Design Specification [Note (1)]					
	Design	Service Level A	Service Level B	Service Level C	Service Level D	Test Loading
Tension and shear	$K_{bo} = 1.0$	$K_{bo} = 1.0$	$K_{bo} = 1.15$	$K_{bo} = 1.25$	[Note (2)]	$K_{bo} = 1.25$

GENERAL NOTE:

K_{bo} = stress limit factor applicable to the Design allowable tensile and shear stresses

NOTES:

- (1) Not to be used for friction type connections.
(2) Use Appendix F.

TABLE NF-3225.2-1 STRESS LIMIT FACTORS FOR CLASS 1, 2, 3, AND MC BOLT DESIGN BY ANALYSIS

(3) partial penetration, single welded between the end surface of a closed tubular section or a closed formed section, Fig. NF-3226.1-1, sketch (h);

(4) the applicable welds may be square groove, bevel groove, J groove, flare V groove or flare bevel groove.

NF-3226.2 Stress Intensities and Stress Limits for Welded Joints in Plate- and Shell-Type Supports

(a) *Design Limits.* The stress intensity and allowable stress limits which must be satisfied for welds for the Design Loadings stated in the Design Specification shall be the following.

(1) *Full Penetration Groove Welds.* The stress intensity limits for full penetration groove welds shall not exceed the applicable stress intensity value for the base metal being joined, as specified in NF-3221.1 and Table NF-3324.5(a)-1. See NF-3111.

(2) *Partial Penetration Groove Welds*

(a) *Compression Normal to Effective Throat or Shear on Effective Throat.* The stress intensity and stress limits shall be the same as those for the base metal as required in NF-3221.1.

(b) *Tension Normal to the Axis on the Effective Throat.* The stress limits shall be as specified in Table NF-3324.5(a)-1.

(3) *Fillet Welds.* The allowable stress limits for fillet welds shall be as specified in Table NF-3324.5(a)-1.

(b) *Service Limits, Level A Through D, and Test.* The rules and stress limits which must be satisfied for welds for any Level A through D Service and Test Loadings stated in the Design Specification are those given in NF-3226.2(a) multiplied by the appropriate base material stress limit factor given in Table NF-3622(b)-1 for Piping Supports and Table NF-3522(b)-1 for Component Supports.

(c) The effective sizes of welds shall be as given in NF-3324.5(d) and NF-3324.5(f).

NF-3250 DESIGN BY ANALYSIS FOR CLASS 2 AND MC

Plate- and Shell-Type Supports may be designed by either elastic or limit analysis, limits for which are given in the following subparagraphs. Limits for bolts and welds are given in NF-3255 and NF-3256. For general requirements and definitions, see NF-3100 and NF-3210.

NF-3251 Stress Limits

NF-3251.1 Design Loadings.

The stress² limits are satisfied for the Design Loadings (NCA-2142.1) stated in the Design Specifications if the requirements of Eqs. (1) and (2) are met.

$$(1) \sigma_1 \leq 1.0S$$

$$(2) \sigma_1 + \sigma_2 \leq 1.5S$$

² Stress means the maximum normal stress (principal stress).

where

σ_1

= membrane stress, ksi, which is the average stress across the solid section under consideration. It includes the effects of discontinuities, but not local stress concentrations.

σ_2

= bending stress, ksi, which is the linear varying portion of the stress across the solid section under consideration. It excludes the effects of discontinuities and concentrations.

FIG. NF-3226.1(a)-1 TYPICAL WELD DETAILS REFERENCED

S

= allowable stress value, ksi, from the applicable table of Section II, Part D, Subpart 1, as referenced in Table NF-2121(a)-1

GENERAL NOTES:

- (a) $l \geq 3y$, where l is required length of taper and y is the offset between the adjacent surfaces of abutting sections.
- (b) Length of required taper l may include the width of the weld.
- (c) In all cases l shall not be less than $3y$.

FIG. NF-3226.1(a)-2 BUTT WELDING OF PLATES OF UNEQUAL THICKNESS

FIG. NF-3226.1(a)-2 BUTT WELDING OF PLATES OF UNEQUAL THICKNESS

NF-3251.2 Service Loadings - Service Level A Through D.

The rules and stress limits which must be satisfied in an elastic analysis for any Level A through D Service Loading stated in the Design Specification are those given for Design Loadings in NF-3251.1 multiplied by the appropriate stress limit factor specified in Tables NF-3552(b)-1 and NF-3652(b)-1.

NF-3251.3 Test Loadings.

The rules and stress limits which must be satisfied for any Test Loadings stated in the Design Specification are those given for Design Loadings in NF-3251.1 multiplied by the appropriate stress limit factor specified in Tables NF-3552(b)-1 and NF-3652(b)-1.

NF-3251.4 Limit Analysis.

The limits for Class 1 Plate- and Shell-Type Supports designed by limit analysis apply.

NF-3252 Special Stress Limits

The following deviations from the basic stress limits are provided to cover special Service Loadings or configurations. Some of these deviations are more restrictive and some are less restrictive than the basic stress limits. In cases of conflict between these requirements and the basic stress limits, the rules of this paragraph take precedence for the particular situations to which they apply.

NF-3252.1 Bearing Loads

(a) The average bearing stress for resistance to crushing under the maximum load, experienced as a result of Design Loadings, Test Loadings, or any Service Loadings, shall be limited to S_y at temperature, except that when the distance to a free edge is larger than the distance over which the bearing load is applied, a stress of $1.5S_y$ at temperature is permitted.

(b) When bearing loads are applied near free edges, such as at a protruding ledge, the possibility of a shear failure shall be considered. In the case of load controlled stress only, the average shear stress shall be limited to $0.6S$ in the case of primary stress (NF-3121.2).

Page 55

(c) When considering bearing stresses in pins and similar members, the S_y at temperature value is applicable, except that a value of $1.5S_y$ may be used if no credit is given to the bearing area within one pin diameter from a plate edge.

NF-3252.2 Pure Shear

(a) The average primary shear stress across a section loaded in pure shear, experienced as a result of Design Loadings, Test Loadings, or any Service Loadings, shall be limited to $0.6S$.

(b) The maximum primary shear, experienced as a result of Design Loadings, Test Loadings, or any Service Loadings exclusive of stress concentration at the periphery of a solid circular section in torsion, shall be limited to $0.8S$.

NF-3255 Design of Bolting

The provisions of NF-3225 apply.

NF-3256 Design of Welded Joints

NF-3256.1 Permissible Types of Welded Joints in Plate- and Shell-Type Supports.

All welded joints in Plate- and Shell-Type Supports shall be continuous and shall be of one of the types listed in (a) through (d) below. Typical examples of those permitted types are shown in Fig. NF-3256.1-1. Fillet and partial penetration welds shall meet the requirements of NF-3324.5(d), except that NF-3324.5(d)(7) does not apply. Plug and slot welds shall meet the requirements of NF-3324.5(e). Lap joints shall meet the requirements of NF-3324.3.

(a) *Butt Joints.* Butt joints shall be one of the following:

(1) full penetration, single and double welded, Fig. NF-3256.1-1, sketches (a-1) and (a-2);

(2) partial penetration, double welded, Fig. NF-3256.1-1, sketch (b);

(3) when angle joints are used for connecting a transition in diameter to a cylinder, the angle α of Fig. NF-3256.1-1, sketch (n) shall not exceed 30 deg.

(4) A tapered transition having a length not less than three times the offset between the adjacent surfaces of abutting sections, as shown in Fig. NF-3226.1(a)-2, shall be provided at joints between sections that differ in thickness by more than one-fourth of the thickness of the thinner section or by more than $\frac{1}{8}$ in. (3.2 mm), whichever is less. The transition may be formed by any process that will provide a uniform taper. The weld may be partly or entirely in the tapered section or adjacent to it.

(5) When the use of backing rings will result in undesirable conditions such as severe stress or corrosion, the requirements of NF-4240 shall be met.

(b) *Corner Joints.* Corner joints shall be one of the following:

- (1) full penetration, as shown in Fig. NF-3256.1-1, sketch (c);
- (2) partial penetration with a fillet weld as shown in Fig. NF-3256.1-1, sketches (d) and (e).
- (c) *Tee Joints.* Tee joints shall be one of the following:
 - (1) full penetration, single or double welded, Fig. NF-3256.1-1, sketches (f-1), (f-2), and (h);
 - (2) partial penetration, with or without additional fillet welds, Fig. NF-3256.1-1, sketch (g);
 - (3) partial penetration, single welded between a plate and the end surface of a closed tubular section or a closed formed section, Fig. NF-3256.1-1, sketch (j);
 - (4) fillet, double welded, Fig. NF-3256.1-1, sketch (k-1); single welded when double members are used, Fig. NF-3256.1-1, sketch (k-2);
 - (5) fillet, single welded between a flat surface and the end surface of a closed tubular section or a closed formed section, Fig. NF-3256.1-1, sketch (l);
- (d) *Lap Joints.* Lap joints shall be fillet, double welded, Fig. NF-3256.1-1, sketch (m).
- (e) The applicable welds for the joints permitted in (a) through (d) above are:
 - (1) square groove, bevel groove, J groove, flare bevel groove, U groove and V groove.
 - (2) plug and slot welds are permitted in (c) and (d) only.
 - (3) Fillet welds are permitted in (c)(4), (c)(5), and (d) only.

NF-3256.2 Allowable Stress Limits

- (a) *Design Limits.* The allowable stress limits which must be satisfied for the Design Loadings stated in the Design Specification shall be the following.
 - (1) *Full Penetration Groove Welds.* The allowable stress limits for full penetration groove welds shall not exceed the applicable allowable stress value for the base metal being jointed, as specified in NF-3251.1 and Table NF-3324.5(a)-1.
 - (2) *Partial Penetration Groove Welds*
 - (a) *Compression Normal to Effective Throat or Shear on Effective Throat.* The allowable stress limits shall be as specified in Table NF-3324.5(a)-1.
 - (b) *Tension Normal to the Axis on the Effective Throat.* The stress limits shall be as specified in Table NF-3324.5(a)-1.

GENERAL NOTE:

For weld sketches (c), (d), (e), (f-1), (f-2), (g), (k-1), and (k-2), the welds may be intermittent for class 3 only.

FIG. NF-3256.1-1 PERMISSIBLE WELDED JOINTS FOR CLASS 2, 3, AND MC PLATE- AND SHELL-TYPE SUPPORTS

FIG. NF-3256.1-1 PERMISSIBLE WELDED JOINTS FOR CLASS 2, 3, AND MC PLATE- AND SHELL-TYPE SUPPORTS

(3) *Fillet Welds.* The allowable stress limit for fillet welds shall be as specified in Table NF-3324.5(a)-1.

(b) Service Limits. Level A Through D, and Test. The rules and stress limits which must be satisfied for welds for any Level A through D Service and Test Loading stated in the Design Specification are those given in NF-3356.2(a) multiplied by the appropriate base material stress limit factor given in Table NF-3652(b)-1 for Piping Supports and Table NF-3562(b)-1 for Component Supports.

NF-3256.3 Effective Size.

The effective sizes of welds shall be as given in NF-3324.5(d), (e), and (f).

NF-3260 DESIGN BY ANALYSIS FOR CLASS 3

NF-3261 Stress Limits

The design of Class 3 supports shall be in accordance with the requirements of NF-3250 using one of the design procedures indicated in Table NF-3131(a)-1 for Class 3 construction.

NF-3265 Design of Bolting

The provisions of NF-3225 apply.

NF-3266 Design of Welded Joints

The types of welded joints shall be as stipulated in NF-3256 for Class 2 and MC supports, except that for groove welded T-joints, groove welded corner joints, and fillet welded T-joints, as listed in NF-3256.1(a)(2) and (3), the welds may be intermittent instead of continuous. Intermittent fillet welds shall meet the requirements of NF-3324.5(d)(7). The allowable stress limits shall be as stipulated in NF-3256.2.

NF-3270 EXPERIMENTAL STRESS ANALYSIS

Supports may be designed by experimental stress analysis in accordance with Appendix II (Section III, Division 1, Appendices).

NF-3280 DESIGN BY LOAD RATING

NF-3281 Procedure for Load Rating

The procedure for load rating shall consist of imposing a total load on one or more duplicate full-size samples of a support equal to or less than the load under which the support fails to perform its required function. Full-size samples composed of various parts may have each part or a number of parts load rated, provided that all parts in the load path are either load rated or otherwise qualified per NF-3200, or by experimental stress analysis. When parts are connected by bolting or welding, the connection shall be either load rated or qualified per NF-3225 or NF-3226. Should more than one part be load rated in a single load test, then the load rating equations of NF-3280 shall be evaluated for each part using the part's $S_{y(alt)}$ and $S_{u(alt)}$ values. The part having the lowest load rating shall establish the load rating for the combination of parts. A single test sample is permitted but, in that case, the load ratings shall be reduced by 10%. Otherwise, tests shall be run on a statistically significant number of samples. The permissible types of welded joints shall be as permitted for the specific class of construction in NF-3226.1, NF-3256.1, and NF-3266. The full-size sample shall be fabricated for testing using welds not exceeding weld sizes stipulated in the Design Drawings. Bolted joints in the test sample shall be made up using the lowest strength bolt material and minimum edge distance allowed by the specification.

NF-3282 Load Ratings in Relation to Design Service and Test Loadings

The load rating for Design Loadings shall be determined in accordance with the requirements for Service Level A limits. The load ratings for Service Loadings for which Level A, Level B, or Level C Limits have been designated shall be determined by means of the equations in the following subparagraphs. For Level D Limits, see Appendix F of Section III, Division 1, Appendices. The load rating for Test Loadings shall be determined in accordance with the requirements for Service Level B limits.

NF-3282.1 Nomenclature.

The symbols used in this paragraph are defined as follows:

TL_y	= support test load at or below yield
TL_u	= support test load at which a substantial increase in load displacement results in zero or negative increase in actual support load
S	= allowable stress value at the Design Temperature (NF-3112.1) from the applicable tables of Section II, Part D, Subpart 1, ksi
S_u	= specified minimum tensile strength of the material used in the support as given in the applicable tables of Section II, Part D, Subpart 1, ksi
$S_{u(act)}$	= actual tensile strength of the material used in
	the part or support which had reached ultimate capacity during the test
$S_{y(act)}$	= actual yield strength of the material used in the part or support which yielded during the test
KI	= load rating coefficient for support in compression

Page 58

NF-3282.2 Plate- and Shell-Type Supports.

The load ratings for Plate- and Shell-Type Supports for the Service Loadings shall be determined by the following equations:

Design and Level A Limits (lower of the two values)

$$\text{load rating}_{(yield)} = TL_y \times 1.0 \frac{S}{S_{y(act)}} \quad (5)$$

$$\text{load rating}_{(ult.)} = TL_u \times 1.0 \frac{S}{S_{u(act)}}$$

(5)

Test and Level B Limits (lower of the two values)

$$\text{load rating}_{(\text{yield})} = TL_y \times 1.33 \frac{S}{S_{y(\text{act})}} \quad (6)$$

$$\text{load rating}_{(\text{ult.})} = TL_u \times 1.33 \frac{S}{S_{u(\text{act})}}$$

(6)

Level C Limits (lower of the two values)

$$\text{load rating}_{(\text{yield})} = TL_y \times 1.5 \frac{S}{S_{y(\text{act})}} \quad (7)$$

$$\text{load rating}_{(\text{ult.})} = TL_u \times 1.5 \frac{S}{S_{u(\text{act})}}$$

(7)

NF-3282.3 Supports Loaded in Compression.

The load rating for supports loaded in compression shall be determined for Service Level A, B, and C by the methods of NF-3282.2. In addition, for cases where buckling governs, TL_u shall be corrected for the ratio of Young's Modulus at the Design Temperature to Young's Modulus at the test temperature. The load rating shall be determined by the following equations:

Design and Level A Limits

$$\text{load rating} = 0.50 Kl \times TL_u$$

Test and Level B Limits

$$\text{load rating} = 0.50 Kl \times TL_u$$

Level C Limits

$$\text{Load rating} = 0.50 Kl \times TL_u$$

Kl

= 1.0 for elastic buckling

$$Kl = \frac{S_y}{S_{y(\text{act})}} \text{ for inelastic buckling}$$

NF-3282.4 Alternative Load Rating Method Using TL_y or TL_u Test Results Only.

Either TL_y or TL_u test results may be used to establish a support load rating, provided the load rating as determined by the method of NF-3282.2 or NF-3282.3 is modified as follows.

(a) For load rating based on TL_y test results only:

(1) for supports constructed of materials having definitely determinable yield points and specified minimum S_y/S_u ratios not greater than 0.625, the load rating shall be multiplied by 0.83. If $S_{y(\text{act})}$ of the material is not known, 150% of the material specified minimum yield strength shall be assumed as the $S_y/S_{y(\text{act})}$ in place of multiplier 0.83;

(2) for supports constructed of carbon steel with specified minimum tensile strengths of not over 70,000 psi (480 MPa), $S_{y(\text{act})}$ shall be increased by 5,000 psi (34 MPa) prior to determining the load rating;

(3) for all other materials the determined load rating shall be multiplied by 0.67.

For supports loaded in compression, a TL_u test shall be performed with the compressive load rating determined in accordance with NF-3282.3.

(b) For load rating based on TL_u test results, the determined load rating shall be multiplied by 0.50.

NF-3300 DESIGN RULES FOR LINEAR-TYPE SUPPORTS

NF-3310 GENERAL REQUIREMENTS

This Subarticle provides rules for the design of Linear-Type Supports by either linear elastic analysis (NF-3320) or plastic (limit) analysis (NF-3340). Linear elastic analytical procedures are also provided (NF-3330) for the design of members and connections which will be subjected to high cycle fatigue conditions in service.

Page 59

NF-3311 Design Considerations

NF-3311.1 Linear Elastic Analysis.

The rules for linear elastic analysis are based on the yield strength values at temperature of the materials used in constructing linear type supports which are set forth in Tables 4 and Y-1 of Section II, Part D, Subpart 1. The allowable stresses are determined in NF-3320 by applying factors of safety dependent on the structural member involved to these specified yield strength values.

S_m values for bolting materials listed in Table 4, Section II, Part D, Subpart 1 are based on $(1/3)S_y$. Multiply S_m by three to arrive at S_y values for the material (round up to next higher 0.5 ksi) if an S_y value for the material is needed.

NF-3311.2 High Cycle Fatigue Analysis.

The rules for designing Linear-Type Supports given in NF-3330 are essentially the same as those given in NF-3320 for linear elastic analysis, except that the maximum range of stress, namely, the difference between the minimum and maximum value of the stress throughout each cycle and the frequency with which the support will be subjected to this range of stress, shall be taken into consideration when so stipulated by the Design Specification (NCA-3250).

NF-3311.3 Limit Analysis.

The rules for limit (plastic) analysis given in NF-3340 may be used as an alternative to the linear elastic analysis method. These rules permit proportioning Linear-Type Supports on the basis of limit design by determining their lower bound collapse loads. The requirements set forth in NF-3320 governing allowable stresses to be used in designing Linear-Type Supports are waived when the limit design procedure is employed, but all other pertinent provisions of NF-3320 shall apply.

NF-3311.4 Basis for Determining Stress in Design by Analysis.

The theory of failure used in the rules for the design of Linear-Type Supports is the maximum stress theory. In the maximum stress theory, the controlling stress is the maximum principal stress.

NF-3311.5 Terms Relating to Design by Analysis.

Terms used in the design of Linear-Type Supports by stress analysis are defined in NF-3313.

NF-3312 Analysis Methods

Linear-Type Supports may be designed by either elastic or limit analysis, limits for which are given in the following subparagraphs.

NF-3312.1 Elastic Analysis.

In elastic analysis it is assumed that all component and support stiffnesses remain constant.

(a) *Design Limits.* The rules and stress limits which must be satisfied in an elastic analysis for any Design Loading shall be stated in the Design Specification.

(b) *Service Limits, Level A Through D.* The rules and stress limits which must be satisfied in an elastic analysis for any Level A through D Service Loading stated in the Design Specification are those given in NF-3321 multiplied by the appropriate stress limit factor from Tables NF-3523(b)-1 and NF-3623(b)-1 for the particular loading and stress category.

(c) *Test Limits.* The rules and stress limits which must be satisfied for any Test Loadings stated in the Design Specification are those given in NF-3321 multiplied by the appropriate stress limit factor in Tables NF-3523(b)-1 and NF-3623(b)-1 under Test Loadings.

NF-3313 Nomenclature and Numbering of Equations

NF-3313.1 Nomenclature.

Except where symbols are used in the text of the paragraphs which follow to represent the value of complex algebraic expressions, the nomenclature adopted in NF-3300 is defined as follows:

A	= gross area of an axially loaded compression member, sq in.
A_b	= nominal body area of a fastener, sq in.; area of an upset rod based upon the major diameter of its threads, i.e., the diameter

of a coaxial cylinder which would bound the crests of the upset threads, sq in.

A_e	= effective net area of an axially loaded tension member, sq in.
A_f	= area of compression flange, sq in.
A_n	= net area of an axially loaded tension member, sq in.
A_{st}	= cross-sectional area of stiffener or pair of stiffeners, sq in.
A_w	= area of girder web, sq in.
C	= ratio of bolt tensile strength to tensile strength of connected part
C_b	= bending coefficient dependent upon moment gradient
C_c	= slenderness ratio separating elastic and inelastic buckling
C'_c	= effective column slenderness ratio
C_m	= coefficient applied to bending term in interaction equation and dependent upon column curvature caused by applied moments

Page 60

C_t	= reduction coefficient in computing effective net area of an axially loaded tension member
C_v	= ratio of critical web stress, according to the linear buckling theory, to the shear yield stress of web material
C_1	= increment used in computing minimum spacing of oversized and slotted holes
C_2	= increment used in computing minimum edge distance for oversized and slotted holes
D	= factor dependent upon type of transverse stiffeners = outside diameter of tubular members, in.
E	= modulus of elasticity of steel, ksi
F_a	= axial compressive stress permitted in the absence of bending moment, ksi
F_{as}	= axial compressive stress permitted in the absence of bending moment, for bracing and other secondary members, ksi
F_b	= bending stress permitted in the absence of axial force, ksi
F'_b	= allowable bending stress in compression flange of plate girders as reduced for hybrid girders or because of large web depth-thickness ratio, ksi
F'_e	= Euler stress divided by factor of safety, ksi
F_p	= allowable bearing stress on the projected area of bolts or pins, or on contact area of milled surfaces and ends of rollers, rockers, or fitted bearing stiffeners at temperature, ksi

F_{sr}	= stress range, ksi
F_t	= allowable tensile stress, ksi
F_{tb}	= allowable tensile stress at temperature, ksi
F_v	= allowable shear stress, ksi
F_{vb}	= allowable shear stress at temperature, ksi
F_{yc}	= column yield stress, ksi
F_{yst}	= stiffener yield stress, ksi
K	= effective length factor
L	= span length = distance from center of bolt hole to edge of connected part, in.
M	= moment, in.-kip (NF-3320); factored bending moment, in.-kip (NF-3340)
M'	= lesser of the factored moments at the ends of unbraced segment, in.-kip
M_1	= smaller moment at end of unbraced length of beam column, in.-kip
M_2	= larger moment at end of unbraced length of beam column, in.-kip
M_m	= critical moment that can be resisted by a plastically designed member in the absence of axial load, in.-kip
M_p	= plastic moment, in.-kip
N	= length of bearing of applied load, in.
P	= force transmitted by a fastener, kips (NF-3320); factored axial load, kips (NF-3340) axial load, kips (NF-3340)
P_{bf}	= factored beam flange or connection plate force in a restrained connection = the computed force delivered by the flange or moment connection plate, multiplied by five-thirds when the computed force is due to live and dead loads only, or by four-thirds when the computed force is due to live and dead loads in conjunction with wind or earthquake forces, kips
P_{cr}	= maximum strength of axially loaded compression member or beam, kips
P_e	= Euler buckling load, kips
P_s	= maximum slip resistance of the joint, lb
P_y	= axial plastic load, equal to member area times specified minimum yield stress, kips
Q_a	= ratio of effective area of an axially loaded member to its total area

Q_s	= axial stress reduction factor
R	= reaction or concentrated transverse load applied to beam or girder, kips; radius, in.
S_u	= tabulated values of ultimate tensile strength of material at temperature (Table U, Section II, Part D, Subpart 1), ksi
S_y	= yield strength at temperature (Table Y-1, Section II, Part D, Subpart 1), ksi
T_b	= specific pretension of a high strength bolt, kips
T_i	= initial clamping force per bolt, lb
V_u	= shear produced by required factored loading, ultimate load, kips
Y	= ratio of yield stress of web steel to yield stress of stiffener steel
Z_x	= plastic section modulus for axis of bending, in. ³
a	= clear distance between transverse stiffeners; dimension parallel to the direction of stress, Table NF-3332.3-1, in.
d	= distance required at ends of welded partial length cover plate to develop stress, in.
b	= actual width of stiffened and unstiffened compression elements
	= dimensions normal to the direction of stress, Table NF-3332.3-1, in.
b_e	= effective width of stiffened compression element, in.
b_f	= flange width of rolled beam or plate girder, in.
d	= depth of beam or girder
	= diameter of roller or rocker bearing
	= nominal diameter of fastener, in.
d_c	= column web depth clear of fillets, in.
e	= horizontal displacement, in the direction of the span, between top and bottom of simply supported beam at its ends, in.

f	= axial compression stress on member based on effective area, ksi
f_a	= computed axial stress, ksi
f_b	= computed bending stress, ksi
f_c	= specified compression strength of concrete, ksi
f_p	= computed bearing stress, ksi

f_t	= computed tensile stress, ksi
f_v	= computed shear stress, ksi
f_{vs}	= shear between girder web and transverse stiffeners, kips/linear in. of single stiffener or pair of stiffeners
g	= transverse spacing (gage) between successive holes in line of stress, in.
h	= clear distance between flanges of a beam or girder at the section under investigation, in.
k	= coefficient relating linear buckling strength of a plate to its dimensions and condition of edge support = also distance between outer face of column flange and web toe of its fillet if column is a rolled shape, or equivalent distance if column is a welded shape, in.
k_s	= slip coefficient for the particular surface condition taken from Table NF-3324.6(a)(4)-1
l	= for beams, distance between cross section braced against twist or lateral displacement of the compression flange, in. = for columns, actual unbraced length of member, in., unsupported length of lacing bar, in.
l_b	= actual unbraced length in plane of bending, in.
l_{cr}	= critical unbraced length adjacent to plastic hinge, in.
m	= number of shear planes per bolt
n	= number of bolts in the joint
r	= governing radius of gyration, in.
r_b	= radius of gyration about axis of concurrent bending, in.
r_c	= radius of gyration of a section comprising the compression flange plus one-third of the compression web area, taken about an axis in the plane of the web, in.
r_y	= radius of gyration of a member about its weak axis, in.
s	= longitudinal center-to-center spacing (pitch) of any two consecutive holes, in.
t	= girder, beam, or column web thickness, in.; thickness of a connected part, in. = wall thickness of a tubular member, in.
t_b	= thickness of beam flange or moment connection plate at rigid beam to column connection, in.
t_f	= flange thickness, in.
t_l	= thickness of thinner part joined by partial penetration groove weld, in.
x	= subscript relating to bending about the strong principal axis

y	= subscript relating to bending about the weak principal axis
α	= ratio of hybrid girder web yield stress to flange yield stress
Δ	= displacement of the neutral axis of a loaded member from its position when the member is not loaded, in.

NF-3313.2 Numbering of Equations.

A separate series of equation numbers is used for each paragraph and each series, beginning with Eq. (1).

NF-3320 DESIGN BY LINEAR ELASTIC ANALYSIS FOR CLASS 1

NF-3321 General Design Requirements

NF-3321.1 Design and Service Conditions

(a) Except as otherwise provided in this Subarticle, all items of the structure shall be so proportioned that the stress, ksi, for Design and Level A Service Limits, shall not exceed the values of NF-3322. For Level B, C, and D Service Limits, allowable stresses may be increased by the factors shown in Tables NF-3523(b)-1 and NF-3623(b)-1. Bearing-type stress limits are excluded from rules for Level D Service Limits.

(b) To avoid column buckling in compression members, local instability associated with compression flange buckling in flexural members, and web buckling in plate girders, the allowable stress shall be limited to two-thirds of the critical buckling stress.

NF-3321.2 Design for High Cycle Fatigue Conditions.

Design for high cycle fatigue conditions shall be in accordance with the requirements of NF-3330, using the allowable stresses of NF-3322 as modified by NF-3332.4.

NF-3322 Design Requirements for Structural Steel Members

NF-3322.1 Allowable Stresses - Design and Level A Service Conditions

(a) *Stress in Tension.* The allowable stress in tension shall be as given in (a)(1), (2), and (3) below:

(1) Except for pin-connected and threaded members, F_t shall be:

$$(1) F_t = 0.60S_y$$

but not more than 0.5 times S_u on the effective net area.³

(2) For pin-connected members, using the net area.³

$$(2) F_t = 0.45S_y$$

(3) For threaded parts in tension, see NF-3324.6(a)(1).

(b) *Stress in Shear*

(1) Except as provided in (b)(2) below and NF-3324.6(a)(2), on the cross-sectional area effective in resisting shear:

$$(3a) F_v = 0.40S_y$$

The effective area in resisting shear of rolled and fabricated shapes may be taken as the overall depth times the web thickness.

(2) At the beam end connections where the top flange is coped, and in similar situations where failure might occur by shear along a plane through the fasteners, or by a combination of shear along a plane through the fasteners plus tension

along a perpendicular plane, on the effective area in resisting tearing failure shall be:

$$(3b) F_v = 0.30 S_u$$

The effective area is the minimum net failure surface, bounded by the bolt holes.

(c) *Stress in Compression.* The allowable stress in compression shall be as required by (c)(1) through (3) below. The allowable compressive stress for columns, except those fabricated from austenitic stainless steel, shall be as required by (c)(1). The allowable compressive stress for columns fabricated from austenitic stainless steel shall be as required by (c)(2). The allowable compressive stress for member elements other than columns constructed of any material, including austenitic stainless steel, shall be as required by (c)(3).

(1) *Gross Sections of Columns, Except Those Fabricated of Austenitic Stainless Steel*

(a) *Where Kl/r Is Less Than C_c .* On the gross section of axially loaded compression members whose cross sections meet the provisions of NF-3322.2(d), when Kl/r (the largest effective slenderness ratio of any unbraced segment as defined in NF-3322.2) is less than C_c , the allowable stress in compression shall be:

3 For determination of effective net area, see NF-3322.8.

$$F_a = \frac{[1 - (Kl/r)^2 / 2C_c^2] S_y}{5/3 + [3(Kl/r) / 8C_c] - [(Kl/r)^3 / 8C_c^3]} \quad (4)$$

(4)

where

$$C_c = \sqrt{2\pi^2 E / S_y}$$

(b) *Where Kl/r Is Greater Than C_c .* On the gross section of axially loaded compression members when Kl/r exceeds C_c , the allowable stress in compression shall be:

$$F_a = \frac{12\pi^2 E}{23 (Kl/r)^2} \quad (5)$$

(5)

(c) *Where the Slenderness Ratio Exceeds 120.* On the gross section⁴ of axially loaded bracing and secondary members, when l/r exceeds 120 the allowable stress in compression shall be:

$$F_{as} = \frac{F_a [\text{Eq. (4) or (5)}]}{1.6 - \left(\frac{1}{200r} \right)} \quad (6)$$

(6)

(2) *Gross Sections of Columns Fabricated From Austenitic Stainless Steel.* On the gross section of axially loaded compression members whose cross sections meet the provisions of NF-3322.2(d) the allowable stress in compression shall be as required by (c)(2)(a) and (b) below.

(a) *Where Kl/r Is Less Than or Equal to 120.*

$$F_a = S_y \left(0.47 - \frac{Kl/r}{444} \right) \quad (6a)$$

(6a)

(b) *Where Kl/r Is Greater Than 120.* The following compressive stress limit applies to bracing and secondary members as well as main members.

$$F_a = S_y \left(0.40 - \frac{Kl/r}{600} \right) \quad (6b)$$

(6b)

(3) *Member Elements Other Than Columns*

(a) *Plate Girder Stiffeners.* On the gross area of plate girder stiffeners, the allowable stress in compression shall be:

4 For this case, K is taken as unity.

$$(7) F_a = 0.60 S_y$$

(b) *Webs of Rolled Shapes.* On the web of rolled shapes at the toe of the fillet, the allowable stress in compression shall be:

$$(8) F_a = 0.75 S_y$$

For the use of stiffeners to avoid web crippling, see NF-3322.6(a).

(d) *Stress in Bending.* The allowable bending stress resulting from tension and compression in structural members shall be as required by (d)(1) through (6) below.

(1) *Compact Sections*

(a) Tension and compression on extreme fibers of compact hot rolled or built-up members (except hybrid beams and members made from 65 ksi or greater S_y material) symmetrical about and loaded in the plane of their minor axes and meeting the requirements of Subsection NF shall result in a maximum bending stress:

$$(9) F_b = 0.66 S_y$$

In order to qualify, a member shall meet the requirements of (d)(1)(a)(1) through (7) below.

(1) The flanges shall be continuously connected to the web or webs.

(2) The width-thickness ratio of unstiffened projecting elements of the compression flange [as defined in NF-3322.2(d)] shall not exceed $65/\sqrt{S_y}$.

(3) The width-thickness ratio of stiffened elements of the compression flange [as defined in NF-3322.2(d)] shall not exceed $190/\sqrt{S_y}$.

(4) The depth-thickness ratio of the web or webs shall not exceed the value given by Eq. (10) or (11), as applicable:

$$(10) d/t = (640/\sqrt{S_y}) [1 - 3.74 (f_d/S_y)]$$

when $f_d/S_y \leq 0.16$;

$$(11) d/t = 257/\sqrt{S_y}$$

when $f_d/S_y > 0.16$.

(5) The laterally unsupported length of the compression flange of members other than box-shaped members shall not exceed the value $76b/\sqrt{S_y}$ nor $20,000/[(d/A_f) S_y]$.

(6) The laterally unsupported length of the compression flange of a box-shaped member of rectangular cross section, whose depth is not more than six times the width and whose flange thickness is not more than two times the web thickness, shall not exceed the value:

$$(12) [1950 + 1200 (M_1/M_2)] (b/S_y)$$

except that it need not be less than $1200(b/S_y)$.

(7) The diameter-thickness ratio of hollow circular sections shall not exceed $3300/S_y$.

(b) Beams and girders (except for hybrid girders and members made from 65 ksi or greater S_y material) which meet the requirements of (d)(1)(a)(1) through (7) above and are continuous over supports or are rigidly framed to columns by means of high strength bolts or welds may be proportioned for nine-tenths of the negative moments produced by gravity loading which are maximum at points of support, provided that for such members the maximum positive moment shall be increased by one-tenth of the average negative moments. This reduction shall not apply to moments produced by loading on cantilevers. If the negative moment is resisted by a column rigidly framed to the beam or girder, the one-tenth reduction may be used in proportioning the column for the combined axial and bending loading, provided that the stress f_a due to any concurrent axial load on the member does not exceed $0.15 F_a$

(2) *Members With High Flange Width-Thickness Ratio.* Members which meet the requirements of (d)(1) above,

except that $b_f/2t_f$ exceeds $65/\sqrt{S_y}$ but is less than $95/\sqrt{S_y}$, may be designed on the basis of an allowable bending stress:

$$(13) F_b = S_y [0.79 - 0.002 (b_f/2t_f)\sqrt{S_y}]$$

(3) *Doubly Symmetrical Members With Bending About the Minor Axis.* Tension and compression on extreme fibers of doubly symmetrical I and H shaped members (except for hybrid girders and members made from 65 ksi or greater S_y material) which are bent about their minor axis, meeting the requirements of (d)(1)(a) and (b) above; solid round and square bars; and solid rectangular sections bent about their weaker axis shall not exceed a bending stress of:

$$(14) F_b = 0.75S_y$$

Doubly symmetrical I and H shaped members bent about their minor axis (except for hybrid girders and members made from 65 ksi or greater S_y material), meeting the requirements of (d)(1)(a) above, except

Page 64

where $b_f/2t_f$ exceeds $65/\sqrt{S_y}$ but is less than $95/\sqrt{S_y}$, may be designed on the basis of an allowable bending stress:

$$(15a) F_b = S_y [1.075 - 0.005 (b_f/2t_f)\sqrt{S_y}]$$

Rectangular tubular sections meeting the requirements of (d)(1)(a)(1), (3), and (4) above, and bent about their minor axis, may be designed on the basis of an allowable bending stress:

$$(15b) F_b = 0.66S_y$$

(4) *Box-Type Flexural Members.* Tension and compression on extreme fibers of box-type flexural members whose compression flange or web width-thickness ratio does not meet the requirements of (d)(1) above, but does conform to the requirements of NF-3322.2(d), shall not exceed a bending stress of:

$$(16) F_b = 0.60S_y$$

Lateral torsional buckling need not be investigated for a box section whose depth is less than six times its width. Lateral support requirements for box sections of larger depth-width ratios must be determined by special analysis.

(5) *Miscellaneous Members*

(a) Tension on extreme fibers of flexural members not covered in (d)(1) through (4) above, shall not exceed a bending stress as determined by using Eq. (16).

(b) Compression on extreme fibers of flexural members included in (d)(5)(a) above, meeting the requirements of NF-3322.2(d)(1)(b), and having an axis of symmetry in and loaded in the plane of their web and compression on extreme fibers of channels⁵ bent about their major axis, shall have the larger value of bending stress computed by Eqs. (17), (18), and (19), as applicable, but not more than $0.60S_y$.⁶

When

$$[(102 \times 10^3 C_b) / S_y]^{1/2} \leq l / r_c \leq [(510 \times 10^3 C_b) / S_y]^{1/2}$$

then

$$F_b = \{2/3 - [S_y (l/r_c)^2 / (1530 \times 10^3 C_b)]\} S_y \quad (17)$$

(17)

5 Only Eq. (19) is applicable to channels.

6 See NF-3322.3 for further limitations in plate girder flange stress.

When

$$l/r_c \geq \sqrt{(510 \times 10^3 C_b) / S_y}$$

then

$$(18) F_b = (170 \times 10^3 C_b) / (l/R)^2$$

When the compression flange is solid and approximately rectangular in cross section and its area is not less than that of the tension flange,

$$(19) F_b = (12 \times 10^3 C_b) / (l d / A_f)$$

where

C_b

$= 1.75 + 1.05(M_1/M_2) + 0.3 (M_1/M_2)^2 \leq 2.3$, where M_1 is the smaller and M_2 is the larger bending moment at the ends of the unbraced length taken about the strong axis of the member, and where M_1/M_2 (the ratio of end moments) is positive when M_1 and M_2 have the same sign (reverse curvature bending) and is negative when they are of opposite signs (single curvature bending). When the bending moment at any point within an unbraced length is larger than that at both ends of this length, the value of C_b shall be taken as 1. When computing F_{bx} and F_{by} to be used in Eq. (20), C_b may be computed by the equation given above for frames subject to joint translation. C_b may conservatively be taken as 1 for cantilever beams.⁷

For cantilevers braced against twist only at the support, l may be conservatively taken as the actual length.

(c) For hybrid plate girders, S_y for Eqs. (17) and (18) is the yield stress of the compression flange. Equation (19) shall not apply to hybrid girders.

(6) *Miscellaneous Members Braced Laterally*. Compression in extreme fibers of flexural members meeting the requirements of NF-3322.2(d)(1)(b), but not included in (d)(5)(b) above, shall result in a maximum bending stress as determined by using Eq. (16), provided that sections bent about their major axis are braced laterally in the region of compression stress at intervals not exceeding $76b_f \sqrt{S_y}$.

⁷ For the use of larger C_b values, see: The Structural Stability Research Council, *Guide to Stability Design Criteria for Metal Structures*, 3rd edition, p. 135.

(e) *Combined Stresses*

(1) *Axial Compression and Bending*. For members subjected to both axial compression and bending, including bending moment resulting in secondary stress,

stresses shall be proportioned to satisfy the requirements of Eqs. (20), (21), and (22):

$$\frac{f_a}{F_a} + \frac{C_{mx} f_{bx}}{(1 - f_a / F'_{ex}) F_{bx}} + \frac{C_{my} f_{by}}{(1 - f_a / F'_{ey}) F_{by}} \leq 1.0 \quad (20)$$

$$\frac{f_a}{0.60 S_y} + \frac{f_{bx}}{F_{bx}} + \frac{f_{by}}{F_{by}} \leq 1.0 \quad (21)$$

(20 - 21)

After evaluating primary stresses, the right-hand side of Eq. (22) may be replaced by 1.5 when both primary and secondary bending stresses are considered. When $f_a / F_a \leq 0.15$, Eq. (22) may be used in lieu of Eqs. (20) and (21):

$$\frac{f_a}{F_a} + \frac{f_{bx}}{F_{bx}} + \frac{f_{by}}{F_{by}} \leq 1.0 \quad (22)$$

(22)

In Eqs. (20), (21), and (22), the subscripts x and y indicate the axis of bending about which a particular stress or design property applies, and:

$$F'_e = \frac{12\pi^2 E}{23(Kl_b / r_b)^2}$$

for all members except those fabricated of austenitic stainless steel, or

$$F'_e = \frac{\pi^2 E}{2.15(Kl_b / r_b)^2}$$

for members fabricated of austenitic stainless steel (in the expression for F'_e , as in the case of F_a , F_b , and $0.60S_y$, F'_e may be multiplied by the appropriate stress limit factor from the Tables NF-3523(b)-1 and NF-3623(b)-1 for the particular stress category), where C_m is a coefficient whose value shall be as given in (e)(1)(a) through (c) below:

(a) For compression members in frames subject to joint translation (sidesway), $C_m = 0.85$.

(b) For (rotationally) restrained compression members in frames braced against joint translation and not subject to transverse loading between their supports in the plane of bending,

$$C_m = 0.6 - 0.4 (M_1/M_2)$$

where

$$M_1/M_2$$

= the ratio of the smaller to larger moments at the ends of that portion of the member unbraced in the plane of bending under consideration. M_1/M_2 is positive when the member is bent in reverse curvature and negative when it is bent in single

curvature.

(c) For compression members in frames braced against joint translation in the plane of loading and subjected to transverse loading between their supports, the value of C_m may be determined by rational analysis; however, in lieu of such analysis, the following values may be used:

(1) for members whose ends are restrained (against rotation in the plane of bending):

$$C_m = 0.85$$

(2) for members whose ends are unrestrained (against rotation in the plane of bending):

$$C_m = 1.0$$

(2) *Axial Tension and Bending.* Members subject to both axial tension and bending stresses shall be proportioned at all points along their length to satisfy the requirements of Eq. (21), where f_b is the computed bending tensile stress. However, the computed bending compressive stress, taken alone, shall not exceed the applicable value according to NF-3322.1(d), "Stress in Bending."

(3) *Shear and Tension.* Bolts subject to combined shear and tension shall be proportioned in accordance with the requirements of NF-3324.

(f) *Bearing on Contact Area*

(1) *Milled Surfaces.* On contact area of milled surfaces and ends of fitted bearing stiffness⁸ on projected area of pins in reamed, drilled, or bored holes, the maximum bearing stress shall be:

$$(23) F_p = 0.90S_y$$

(2) *Rollers and Rockers.* The maximum bearing load, kips/linear in., shall be:

$$F_p = \left(\frac{S_y - 13}{20} \right) 0.66d \quad (24a)$$

(24a)

(3) *Bolts.* The maximum bearing load on projected area of bolts in bearing connections shall be:

8 When parts in contact have different yield stresses, S_y shall be the smaller value.

$$(24b) F_p = 1.5S_u$$

(4) *Concrete Bearing.* In the absence of any other Code rules governing bearing stresses on concrete, the maximum bearing stress values shall be as given in (f)(4)(a) and (b) below:

(a) on the full area of a concrete support:

$$(25) F_p = 0.35f_c$$

(b) on less than the full area of a concrete support:

$$(26) F_p = 0.35F_c' \sqrt{A_2/A_1} \leq 0.7f_c$$

where

- A_1 = bearing area, sq in.
 A_2 = full cross-sectional area of concrete support, sq in.

(g) *Single Angle Members.* Single angle members shall be designed in accordance with Appendix NF-II.

NF-3322.2 Stability and Slenderness and Width-Thickness Ratios

(a) General Requirements

(1) General stability shall be provided for the structure as a whole and for each compression element. Design consideration shall be given to significant load effects resulting from the deflected shape of the structure or of individual elements of the lateral load resisting system, including the effects on beams, columns, bracing, connections, and shear walls.

(2) In determining the slenderness ratio of an axially loaded compression member, except as provided in NF-3322.1 (c)(3), the length shall be taken as its effective length Kl , and r shall be taken as the corresponding radius of gyration.

(b) Lateral Stability

(1) *Braced Frames.* In frames [where lateral stability is provided by adequate attachment to diagonal bracing (to shear walls), to an adjacent structure having adequate lateral stability, or to floor slabs (or roofdecks) secured horizontally by walls or bracing systems parallel to the plane of the frame] and in trusses, the effective length factor K for the compression members shall be taken as 1.0, unless analysis shows that a smaller value may be used.

(2) *Unbraced Frames.* In frames where lateral stability is dependent upon the bending stiffness of rigidly connected beams and columns, the effective length Kl of compression members shall be determined by a rational method and shall not be less than the actual unbraced length.

(c) Maximum Slenderness Ratios

(1) The slenderness ratio Kl/r of compression members shall not exceed 200.

(2) The slenderness ratio l/r of tension members, other than rods, preferably should not exceed 240 for main members, and 300 for lateral bracing members and other secondary members.

(d) Width Ratios

(1) Unstiffened Elements Under Compression

(a) *Effective Width.* Unstiffened (projecting) compression elements are those having one free edge parallel to the direction of compression stress. The width of unstiffened plates shall be taken from the free edge to the first row of fasteners or welds; the width of legs of angles, channel and zee flanges, and stems of tees shall be taken as the full nominal dimension; the width of flanges of I and H shaped members and tees shall be taken as one-half of the full nominal width. The thickness of a sloping flange shall be measured at a section halfway between a free edge and the corresponding face of the web.

(b) *Determination of Effective Width.* Unstiffened elements subject to axial compression or compression due to bending shall be considered as fully effective when the width-thickness ratio is not greater than the following:

(1) for single angle struts and double angle struts with separators, $76/\sqrt{F_y}$;

(2) for struts comprising double angles in contact; angles or plates projecting from girders, columns, or other compression members; compression flanges of beams; and stiffeners on plate girders, $95/\sqrt{F_y}$;

(3) for stems of tees, $127/\sqrt{F_y}$.

When the actual width-thickness ratio exceeds these values, the design stress shall be governed by the provisions of (e) below.

(2) Stiffened Elements Under Compression

(a) *Effective Width.* Stiffened compression elements are those having lateral support along both edges which are parallel to the direction of the compression stress. The width of such elements shall be taken as follows:

(1) For webs of rolled, built-up, or formed sections, h is the clear distance between flanges.

(2) For webs of rolled, built-up, or formed sections, d is the full nominal depth.

(3) For flange or diaphragm plates in built-up sections, the width b is the distance between adjacent lines of fasteners or lines of welds.

(4) For flanges of rectangular hollow structural sections, the width b is the clear distance between

webs less the inside corner radius on each side. If the corner radius is not known, the flat width may be taken as the total section width minus three times the thickness.

(b) *Determination of Effective Width.* Stiffened elements subject to axial compression or to uniform compression due to bending, as in the case of the flange of a flexural⁹ member, shall be considered as fully effective when the width-thickness ratio is not greater than the following:

(1) for flanges of square and rectangular box sections of uniform thickness, $238/\sqrt{S_y}$;

(2) for unsupported width of cover plates perforated with a succession of access holes,¹⁰ $317/\sqrt{S_y}$;

(3) for all other uniformly compressed stiffened elements, $253/\sqrt{S_y}$.

Except in the case of perforated cover plates, when the actual width-thickness ratio exceeds these values, the design stress shall be governed by the provisions of (e) below.

(c) *Circular Tubular Elements.* Circular tubular elements subject to axial compression shall be considered as fully effective when the ratio of the outside diameter to the wall thickness is not greater than $3300/S_y$. For diameter to thickness ratios greater than $3300/S_y$ but less than $13,000/S_y$, the calculated stress shall be governed by the provisions of (e) below.

(e) *Slender Compression Elements*

(1) *General Requirements.* Axially loaded members and flexural members, containing elements subject to compression and having a width-thickness ratio in excess of the applicable limit given in (d)(1) and (d)(2) above, shall be proportioned to meet the requirements of the following subparagraphs.

⁹ Webs of flexural members are covered by the provisions of NF-3322.6(a) and NF-3322.6(e)(2) and are not subject to the provisions of this paragraph.

¹⁰ Assumes net area of plate at widest hole as basis for computing compression stresses.

(2) *Unstiffened Compression Elements.* Except as provided herein, stress on unstiffened compression elements, the width-thickness ratio of which exceeds the applicable limit given in (d)(1) above, shall be subject to a reduction of factor Q_s . The value of Q_s shall be determined by Eqs. (27) to (32), as applicable, where b is the width of the unstiffened element as defined in (d)(1) above. When such elements comprise the compression flange of a flexural member, the maximum allowable bending stress shall not exceed $0.6S_y Q_s$, nor the applicable value as provided in (d)(5) or (6) above. The allowable stress of axially loaded compression members shall be modified by the appropriate reduction factor Q_s as provided in (e)(5) below.

(a) For single angles, when

$$76/\sqrt{S_y} < b/t < 155/\sqrt{S_y}$$

then

$$(27) Q_s = 1.340 - 0.00447 (b/t) \sqrt{S_y}$$

when

$$b/t \geq 155/\sqrt{S_y}$$

then

$$(28) Q_s = 15,500/[S_y(b/t)]$$

(b) For angles or plates projecting from columns or other compression members and for projecting elements of compression flanges of girders, when

$$95/\sqrt{S_y/k_c} < b/t < 195/\sqrt{S_y/k_c}$$

then

$$(29) Q_s = 1.293 - 0.00309 (b/t)\sqrt{S_y/k_c}$$

when

$$b/t > 195/\sqrt{S_y/k_c}$$

then

$$(30) Q_s = 26,200 k_c/[S_y(b/t)^2]$$

$$k_c = \frac{4.05}{(h/t)^{0.46}} \text{ if } \frac{h}{t} > 70, \text{ otherwise } k_c = 1.0.$$

(c) For stems of tees, when

$$127/\sqrt{S_y} < b/t < 176/\sqrt{S_y}$$

then

$$(31) Q_s = 1.908 - 0.00715 (b/t) \sqrt{S_y}$$

**TABLE NF-3322.2(e)(2)-1
LIMITING PROPORTIONS FOR CHANNELS AND TEES**

Shape	Ratio of Flange Width to Profile Depth	Ratio of Flange Thickness to Web or Stem Thickness
Built-up or	≤ 0.25	≤ 3.0
rolled channels } Built-up tees	≤ 0.50	≤ 2.0
	≥ 0.50	≥ 1.25
Rolled tees	≥ 0.50	≥ 1.10

TABLE NF-3322.2(e)(2)-1 LIMITING PROPORTIONS FOR CHANNELS AND TEES

when

$$b/t \geq 176/\sqrt{S_y}$$

then

$$(32) Q_s = 20,000/[S_y(b/t)^2]$$

(d) However, unstiffened elements of channels and tees whose proportions exceed the limits of (d)(1) above shall conform to the limits given in Table NF-3322.2(e)(2)-1.

(3) Stiffened Compression Elements

(a) When the width-thickness ratio of uniformly compressed stiffened elements, except for perforated cover plates, exceeds the applicable limit given in (d)(2) above, a reduced effective width b_e shall be used in computing the flexural design properties of the section containing the element and the permissible axial stress, except that the ratio b/t need not be taken as less than the applicable value permitted in (d)(2) above.

(1) For the flanges of square and rectangular sections of uniform thickness:

$$b_e = \frac{253t}{\sqrt{f}} \left[1 - \left(\frac{50.3}{(b/t) \sqrt{f}} \right) \right] \leq b \quad (33)$$

(33)

(2) For other uniformly compressed elements:

$$b_e = \frac{253t}{\sqrt{f}} \left[1 - \left(\frac{44.3}{(b/t) \sqrt{f}} \right) \right] \leq b \quad (34)$$

(34)

where

b

= the actual width, in., of a stiffened compression element as defined in (d)(2) above

f

= computed compressive stress, ksi, in the stiffened elements based on the design properties as specified in (e)(4) below. If unstiffened elements are included in the total cross section for the stiffened element, f must be such that the maximum compressive stress in the unstiffened element does not exceed $F_a Q_s$ or $F_b Q_s$, as applicable.

(b) The allowable stress for axially loaded circular tubular members not meeting the requirements of NF-3322.1(e) above, but having a diameter-to-thickness ratio of less than $13,000/S_y$, shall not exceed either the smaller value determined by NF-3322.1(e) above or:

$$F_a = \left[\frac{662}{D/t} + 0.4S_y \right]$$

(c) When the allowable stresses are increased for Level C Conditions, the effective width b_e shall be determined on the basis of 0.75 times the stress caused by Level C Conditions.

(4) *Design Properties.* Properties of sections shall be determined in accordance with conventional methods, using the full cross section of the member, except as required in (e)(4)(a) and (b) below.

(a) In computing the moment of inertia and section modulus of flexural members with respect to the axis of bending under consideration, the effective width of stiffened compression elements parallel to the axis of bending and having a width-thickness ratio in excess of the applicable limit given in (d)(2) above, rather than the actual width, shall be used, and the axis of bending shall be located accordingly, except that for sections otherwise symmetrical, the properties may conservatively and more easily be computed using a corresponding effective area on the tension side

of the neutral axis as well. That portion of the area which is neglected in arriving at the effective area shall be located at and symmetrical about the center line of the stiffened element to which it applies.

(b) The stress f_a due to axial loading, and the radius of gyration r , shall be computed on the basis of actual cross-sectional area. However, the allowable axial stress F_a as provided in (e)(5) below shall be subject to the form factor:

$$Q_a = \frac{\text{effective area}}{\text{actual area}}$$

where the effective area is equal to the actual area less $\Sigma (b-b_e) t$.

(5) *Axially Loaded Compression Members.* The allowable stress for axially loaded compression members containing unstiffened or stiffened elements shall not exceed:

Page 69

$$F_a = \frac{Q_s Q_a \left[1 - \frac{(Kl/r)^2}{2(C'_c)^2} \right] S_y}{\frac{5}{3} + \frac{3(Kl/r)}{8C'_c} - \frac{(Kl/r)^3}{8(C'_c)^3}} \quad (35)$$

(35)

where

$$C'_c = \sqrt{\frac{2\pi^2 E}{Q_s Q_a S_y}}$$

and

$$Q = Q_s Q_a$$

(a) Cross sections composed entirely of unstiffened elements,

$$Q = Q_s \text{ (i.e., } Q_a = 1.0\text{)}$$

(b) Cross sections composed entirely of stiffened elements,

$$Q = Q_a \text{ (i.e., } Q_s = 1.0\text{)}$$

(c) Cross sections composed of both stiffened and unstiffened elements,

$$Q = Q_s Q_a$$

when the largest effective slenderness ratio of any unbraced segment of the member is neither less than C'_c nor the value given by Eq. (5) when Kl/r exceeds C'_c .

(6) *Combined Axial and Flexural Stress.* In applying the provisions of NF-3322.1(e) to members subject to combined axial and flexural stress and containing stiffened elements whose width-thickness ratio exceeds the applicable limit given in (d)(2) above, the stresses F_a , f_{bx} , and f_{by} shall be calculated on the basis of the section properties as provided in (e)(4) and (5) above, as applicable. The allowable bending stress F_b for members containing unstiffened elements whose width-thickness ratio exceeds the applicable limit given in (d)(1) above shall be the smaller value $0.6S_y Q_s$ or that provided in NF-3322.1(d)(5).

NF-3322.3 Plate Girders, Rolled Beams, and Built-Up Members

(a) *Girders and Rolled Beams.* Rolled or welded shapes, plate girders, and cover-plated beams shall, in general, be proportioned by the moment of inertia of the gross section. No deduction shall be made for shop or field bolt or rivet holes in either flange provided that

$$(35a) 0.5S_u A_{fn} \geq 0.6S_y A_{fg}$$

where A_{fg} is the gross flange area and A_{fn} is the net flange area, calculated in accordance with the provisions of NF-3322.8.

If

$$(35b) \ 0.5S_u A_{fn} < 0.6S_y A_{fg}$$

the member flexural properties shall be based on an effective tension flange area A_{fe}

$$A_{fe} = \frac{5}{6} \frac{S_u}{S_y} A_{fn} \quad (35c)$$

(35c)

(b) *Hybrid Girders.* Hybrid girders may be proportioned by the moment of inertia of their gross section, provided that they are not required to resist an axial force greater than $0.15S_y$ times the area of the gross section, where S_y is the yield stress of the flange material. To qualify as hybrid girders, the flanges at any given section shall have the same cross-sectional area and be made of the same grade of steel.

(c) *Open Box-Type Beams and Grillages.* When two or more rolled beams or channels are used side by side to form a flexural member, they shall be connected together at intervals of not more than 5 ft. Through-bolts and separators may be used, provided that in beams having a depth of 12 in. or more, no fewer than two bolts shall be used at each separator location. When concentrated loads are carried from one beam to the other or distributed between the beams, diaphragms having sufficient stiffness to distribute the load shall be bolted or welded between the beams.

NF-3322.4 Compression Members

(a) Requirements for Fasteners

(1) *Transverse Spacing of Fasteners.* All parts of built-up compression members and the transverse spacing of their lines of fasteners shall meet the requirements of NF-3322.2.

(2) *End Fasteners.* At the ends of built-up compression members bearing on base plates or milled surfaces, all components in contact with one another shall be connected by bolts, spaced longitudinally not more than four diameters apart for a distance equal to $1\frac{1}{2}$ times the maximum width of the member, or by continuous welds having a length not less than the maximum width of the member.

(3) *Intermediate Fasteners.* The longitudinal spacing for intermediate bolts or intermittent welds in built-up members shall be adequate to provide for the transfer

Page 70

of calculated stress. The maximum longitudinal spacing of bolts or intermittent welds connecting two rolled shapes in contact with one another shall not exceed 24 in. In addition, for painted members and unpainted members not subject to corrosion where the outside component consists of a plate, the maximum longitudinal spacing shall not exceed:

(a) $127/\sqrt{S_y}$ times the thickness of the outside plate nor 12 in. when fasteners are not staggered along adjacent gage lines;

(b) $190/\sqrt{S_y}$ times the thickness of the outside plate nor 18 in. when fasteners are staggered along adjacent gage lines.

(b) *Local Slenderness Ratio.* Compression members composed of two or more rolled shapes separated by intermittent fillers shall be connected at these fillers at intervals such that the slenderness ratio Kl/r of either shape, between the

fasteners, does not exceed $\frac{3}{4}$ times the governing slenderness ratio of the built-up member. The least radius of gyration r shall be used in computing the slenderness ratio of each component part. At least two intermediate connectors shall be used along the length of the built-up member.

(c) *Tie Plates.* Open sides of compression members built up from plates or shapes shall be provided with lacing having tie plates at each end and at intermediate points if the lacing is interrupted. Tie plates shall be as near to the ends as practicable. In main members carrying calculated stress, the end tie plates shall have a length of not less than the distance between the lines of bolts or welds connecting them to the elements of the member. Intermediate tie plates shall have a length not less than one-half of this distance. The thickness of tie plates shall be not less than one-fiftieth of the distance between the lines of bolts or welds connecting them to the segments of the members. In bolted construction, the spacing in the direction of stress in tie plates shall be not more than six diameters and the tie plates shall be connected to each segment by at least three fasteners. In welded construction, the welding on each line connecting a tie plate shall aggregate not less than one-third of the length of the plate.

(d) *Lacing.* Lacing, including flat bars, angles, channels, or other shapes employed as lacing, shall be so spaced that the ratio l/r of the flange included between their connections shall not exceed $\frac{3}{4}$ times the governing ratio for the member as a whole. Lacing shall be proportioned to resist a shearing stress normal to the axis of the member equal to 2% of the total compressive stress in the member. The ratio l/r for lacing bars arranged in single systems shall not exceed 140. For double lacing this ratio shall not exceed 200. Double lacing bars shall be joined at their intersections. For lacing bars in compression, the unsupported length of the lacing bar shall be taken as the distance between fasteners or welds connecting it to the components of the built-up member for single lacing, and 70% of that distance for double lacing. The inclination of lacing bars to the axis of the member shall preferably be not less than 60 deg. for single lacing and 45 deg. for double lacing. When the distance between the lines of fasteners or welds in the flanges is more than 15 in. (381 mm), the lacing preferably shall be double or be made of angles.

(e) *Perforated Cover Plates.* The function of tie plates and lacing may be performed by continuous cover plates perforated with a succession of access holes. The unsupported width of such plates at access holes, as defined in NF-3322.2(d)(2), is assumed to be available to resist axial stress, provided that:

- (1) the width-thickness ratio conforms to the limitations of NF-3322.2(d)(2);
- (2) the ratio of length in direction of stress to width of hole shall not exceed 2;
- (3) the clear distance between holes in the direction of stress shall be not less than the transverse distance between nearest lines of connection bolts or welds; and
- (4) the periphery of the holes at all points connecting shall have a minimum radius of $1\frac{1}{2}$ in. (38 mm).

NF-3322.5 Tension Members

(a) *Longitudinal Spacing of Connectors.* The longitudinal spacing of connectors between elements in continuous contact consisting of a plate and a shape or two plates shall not exceed:

- (1) 24 times the thickness of the thinner plate, or 12 in. for painted members or unpainted members not subject to corrosion;
- (2) 14 times the thickness of the thinner plate, or 7 in. for unpainted members of weathering steel subject to atmospheric corrosion.

In a tension member the longitudinal spacing of fasteners and intermittent welds connecting two or more shapes in contact shall not exceed 24 in. (610 mm). Tension members composed of two or more shapes or plates separated by intermittent fillers shall be connected to one another at these fillers at intervals such that the slenderness ratio of either component between the fasteners does not exceed 300.

(b) *Perforated Cover and Tie Plates.* Either perforated cover plates or tie plates without lacing may be used on the open sides of built-up tension members. Tie plates shall have a length not less than two-thirds the distance between the lines of bolts or welds connecting them to the elements of the member. The

thickness of such tie plates shall not be less than one-fiftieth of the distance between these lines. The longitudinal spacing of bolts or intermittent welds at tie plates shall not exceed 6 in. (152 mm). The spacing of tie plates shall be such that the slenderness ratio of any component in the length between tie plates shall not exceed 240.

NF-3322.6 Webs, Flanges, and Stiffeners

(a) *Webs*. The ratio of the clear distance between flanges to the web thickness shall not exceed:

$$(36) \ 14,000/\sqrt{S_y(S_y + 16.5)}$$

except that when transverse stiffeners are provided, spaced not more than $1\frac{1}{2}$ times the girder depth, the limiting ratio may be $2000/\sqrt{S_y}$, where S_y is the yield stress of the compression flange.

(1) *Combined Shear and Tension Stress*. Plate girder webs which depend upon tension field action, as provided in Eq. (45), shall be so proportioned that bending tensile stress due to moment in the plane of the girder web shall not exceed $0.6S_y$, or

$$\left(0.825 - 0.375 \frac{f_v}{F_v}\right) S_y \quad (37)$$

(37)

where

F_v = allowable web shear stress, ksi, according to Eq. (45)

The allowable shear stress in the webs of girders having flanges and webs with yield values greater than 68 ksi shall not exceed the values given by Eq. (44) if the flexural stress in the flange f_b exceeds $0.75F_b$

(2) *Web Crippling*

(a) *Local Web Yielding*. Webs of beams and welded plate girders shall be so proportioned that the compressive stress at the web toe of the fillets, resulting from concentrated loads not supported by bearing stiffeners, shall not exceed the value of $0.75S_y$; otherwise, bearing stiffeners shall be provided. The governing equations shall be:

(1) for interior loads:

$$\frac{R}{t(N + 5k)} \leq 0.66S_y \quad (38)$$

(38)

(2) for end reactions:

$$\frac{R}{t(N + 2.5k)} \leq 0.66S_y \quad (39)$$

(39)

where N is greater than or equal to k for end reactions.

(b) *Stress on Compression Edge of Web Plate.* Bearing stiffeners shall be provided in the webs of members under concentrated loads, when the compressive force exceeds the following limits:

when the concentrated load is applied at a distance not less than $d/2$ from the end of the member:

$$R = 67.5t_w^2 \left[1 + 3 \left(\frac{N}{d} \right) \left(\frac{t_w}{t_f} \right)^{1.5} \right] \sqrt{S_y t_f / t_w} \quad (40)$$

(40)

when the concentrated load is applied less than a distance $d/2$ from the end of the member:

$$R = 34 t_w^2 \left[1 + 3 \left(\frac{N}{d} \right) \left(\frac{t_w}{t_f} \right)^{1.5} \right] \sqrt{S_y t_f / t_w} \quad (41)$$

(41)

where

S_y	= specified minimum yield stress of beam web, ksi
d	= overall depth of the member, in.
t_f	= flange thickness, in.

If stiffeners are provided and extend at least one-half the web depth, Eqs. (40) and (41) need not be checked.

Bearing stiffeners shall be provided in the webs of members with flanges not restrained against relative movement by stiffeners or lateral bracing and subject to concentrated compressive loads, when the compressive force exceeds the following limits:

If the loaded flange is restrained against rotation and $(d_c/t_w)/(l/b_f)$ is less than 2.3:

$$R = \frac{6,800 t_w^3}{h} \left[1 + 0.4 \left(\frac{d_c/t_w}{l/b_f} \right)^3 \right] \quad (41a)$$

(41a)

If the loaded flange is not restrained against rotation and $(d_c/t_w)/(l/b_f)$ is less than 1.7:

$$R = \frac{6,800 t_w^3}{h} \left[0.4 \left(\frac{d_c/t_w}{l/b_f} \right)^3 \right] \quad (41b)$$

(41b)

where

l	= largest laterally unbraced length along either flange at the point of load, in.
b_f	= flange width, in.
d_c	= $d - 2k$ = web depth clear of fillets, in.

Page 72

Equations (41a) and (41b) need not be checked providing $(d_c/t_w)/(l/b_f)$ exceeds 2.3 or 1.7, respectively, or for webs subject to uniformly distributed load.

These stresses shall be computed as required by (a)(2)(b)(1) and (2) below.

(1) Concentrated loads shall be divided by the product of the web thickness and the girder depth or the length of panel in which the load is placed, whichever is the lesser panel dimension.

(2) Distributed loads, kips/linear in. of length, shall be divided by the web thickness.

(b) Flanges

(1) The thickness of outstanding parts of flanges shall conform to the requirements of NF-3322.2(d)(1).

(2) Flanges of welded plate girders may be varied in thickness or width by splicing a series of plates or by the use of cover plates.

(3) The total cross-sectional area of cover plates of bolted girders shall not exceed 70% of the total flange area.

(c) Flange Development

(1) High strength bolts or welds connecting flange to web or cover plate to flange shall be proportioned to resist the total horizontal shear resulting from the bending forces on the girder. The longitudinal distribution of these bolts or intermittent welds shall be in proportion to the intensity of the shear, but the longitudinal spacing shall not exceed the maximum permitted, respectively, for compression or tension members in NF-3322.4(a)(3) or NF-3322.5(a). Additionally, bolts or welds connecting flange to web shall be proportioned so as to transmit to the web any loads applied directly to the flange unless provision is made to transmit such loads by direct bearing.

(2) Partial length cover plates shall be extended beyond the theoretical cut-off point and the extended portion shall be attached to the beam or girder by high strength bolts for friction-type joints or fillet welds adequate at the applicable stresses allowed in NF-3324.6(a), NF-3324.5(d), or NF-3324.4, to develop the cover plate portion of the flexural stresses in the beam or girder at the theoretical cut-off point. In addition, for welded cover plates, the welds connecting

the cover plate termination to the beam or girder in the length d' , defined in (c)(1)(a) through (c) below, shall be adequate at the allowed stresses to develop the cover plate portion of the flexural stresses in the beam or girder at the distance d' from the end of the cover plate. The length d' measured from the end of the cover plate, shall be:

(a) a distance equal to the width of the cover plate when there is a continuous weld equal to or larger than three-fourths of the plate thickness across the end of the plate and continuous welds along both edges of the cover plate in the length d' ;

(b) a distance equal to $1\frac{1}{2}$ times the width of the cover plate when there is a continuous weld smaller than three-fourths of the plate thickness across the end of the plate and continuous welds along both edges of the cover plate in the length d' ;

(c) a distance equal to two times the width of the cover plate when there is no weld across the end of the plate, but continuous welds along both edges of the cover plate in the length d' ;

(d) *Reduction in Flange Stress.* When the web depth-thickness ratio exceeds $760/\sqrt{F_b}$, the maximum stress in the compression flange shall not exceed:

$$F'_b \leq F_b \left[1.0 - 0.0005 \frac{A_w}{A_f} \left(\frac{h}{t} - \frac{760}{\sqrt{F_b}} \right) \right] \quad (42)$$

(42)

where F_b is the applicable bending stress, ksi, given in NF-3322.1(d). The maximum stress in either flange of a hybrid girder shall not exceed the value given in Eq. (42) or:

$$F'_b \leq F_b \left[\frac{12 + (A_w/A_f)(3\alpha - \alpha^3)}{12 + 2(A_w/A_f)} \right] \quad (43)$$

(43)

(e) *Stiffeners*

(1) *Bearing.* Bearing stiffeners shall be placed in pairs at unframed ends on the webs of plate girders and, where required by (a)(2) above, at points of concentrated loads. Such stiffeners, when the load normal to the flange is tensile, shall be welded to the loaded flange and when the load normal to the flange is compressive may be welded or bear on the loaded flange. They shall be designed as columns subject to the provisions of NF-3322.1, assuming the column section to comprise the pair of stiffeners and a centrally located strip of the web whose width is equal to not more than 25 times its thickness at interior stiffeners, or a width equal to not more than 12 times its thickness when the stiffeners are located at the end of the web. The effective length shall be taken as not less than three-fourths of the length of the stiffeners in computing the ratio l/r . Only that portion of the stiffener outside of the flange angle fillet or the flange to

web welds shall be considered effective in bearing.

(2) *Average Web Shear.* Except as provided herein, the largest average web shear f_v , ksi, computed for any condition of complete or partial loading, shall not exceed the value given by Eq. (44):

Page 73

$$F_v = (S_y / 2.89) C_v \leq 0.4 S_y \quad (44)$$

(44)

where

$$\begin{aligned} C_v &= (45,000k) / [S_y(h/t)^2], \text{ when } C_v \text{ is less than } 0.8 \\ &= [190/(h/t)] \sqrt{k/S_y}, \text{ when } C_v \text{ is more than } 0.8 \\ k &= 4.00 + [5.34/(a/h)^2], \text{ when } a/h \text{ is less than } 1.0 \\ &= 5.34 + [4.00/(a/h)^2], \text{ when } a/h \text{ is more than } 1.0 \end{aligned}$$

Alternatively, for girders other than hybrid girders and tapered members, if intermediate stiffeners are provided and spaced to satisfy the provisions of (e)(3) below and if $C_v \leq 1$, the allowable shear given by Eq. (45)¹¹ may be used in lieu of the value given in Eq. (44):

$$F_v = \frac{S_y}{2.89} \left[C_v + \frac{1 - C_v}{1.15 \sqrt{1 + (a/h)^2}} \right] \leq 0.4 S_y \quad (45)$$

(45)

(3) Intermediate Stiffeners

(a) Subject to the limitations of NF-3322.6(a), intermediate stiffeners are not required when the ratio h/t is less than 260 and the maximum web shear stress f_v is less than that permitted for F_v by Eq. (44).

(b) The spacing of intermediate stiffeners, when stiffeners are required, shall be such that the web shear stress will not exceed the value for F_v given by Eq. (44) or (45), as applicable, and the ratio a/h shall not exceed $[260/(h/t)]^2$ or 3.0.

(c) In girders designed on the basis of tension field action, the spacing between stiffeners at end panels, at panels containing large holes, and at panels adjacent to panels containing large holes shall be such that f_v does not exceed the

value for F_v given by Eq. (44).

(4) *Moment of Inertia and Gross Area*

(a) The moment of inertia, in.⁴, of a pair of intermediate stiffeners or a single intermediate stiffener, with reference to an axis in the plane of the web, shall not be less than $(h/50)^4$.

(b) The gross area, sq in., of intermediate stiffeners spaced as required for Eq. (45) (total area, when stiffeners are furnished in pairs), shall be not less than that computed by Eq. (46):

$$A_{st} = \frac{1 - C_v}{2} \left[\frac{a}{h} - \frac{(a/h)^2}{\sqrt{1 + (a/h)^2}} \right] Y D h t \quad (46)$$

(46)

where

D	$= 1.0$ for stiffeners furnished in pairs $= 1.8$ for single angle stiffeners $= 2.4$ for single plate stiffeners
-----	---

11 Equation (45) recognizes the contribution of tension field action.

(c) When the greatest shear stress f_v in a panel is less than that permitted by Eq. (45), this gross area requirement may be reduced proportionately.

(d) Intermediate stiffeners required by Eq. (45) shall be connected for a total shear transfer, kips/linear in. of single stiffener or pair of stiffeners, not less than that computed by Eq. (47):

$$f_{vs} = h \left(\frac{S_y}{340} \right)^{2/3} \quad (47)$$

(47)

This shear transfer may be reduced in the same proportion that the largest computed shear stress f_v in the adjacent panels is less than that permitted by Eq. (45). However, bolts and welds in intermediate stiffeners which are required to transmit to the web an applied concentrated load or reaction shall be proportioned for not less than the applied load or reaction.

(e) Intermediate stiffness may be stopped short of the tension flange, provided bracing is not needed to transmit a concentrated load or reaction; the weld by which intermediate stiffeners are attached to the web shall be terminated not closer than four times nor more than six times the web thickness from the near toe of the web to flange welds. When single stiffeners are used, they shall be attached to the compression flange, if it consists of a rectangular plate, to resist any uplift tendency due to torsion in the plate. When lateral bracing is attached to a stiffener or a pair of stiffeners, these, in turn, shall be connected to the compression flange to transmit 1% of the total flange stress, unless the flange is composed only of angles.

(f) Bolts connecting stiffeners to the girder web shall be spaced not more than 12 in. (305 mm) on center. If intermittent fillet welds are used, the clear distance between welds shall not be more than 16 times the web thickness, or more than 10 in. (254 mm).

(f) *Splices.* Groove welded splices in the plate girders and beams shall develop the full strength of the smaller spliced section; other types of splices in cross sections of plate girders and in beams shall develop the strength required by the stresses at the point of splice.

(g) *Rotational Restraint at Points of Support.* Beams, girders, and trusses shall be restrained against rotation about their longitudinal axis at points of support.

NF-3322.7 Simple and Continuous Spans, and Provision for Expansion

(a) Design Requirements for Spans

(1) *Simple Spans.* Beams, girders, and trusses shall ordinarily be designed on the basis of simple spans whose effective length is equal to the distance between

Page 74

centers of gravity of the members to which they deliver their end reactions.

(2) *Continuous Spans.* When designed on the assumption of full or partial end restraint, due to continuous, semi-continuous, or cantilever action, the beams, girders, and trusses, as well as the sections of the members to which they connect, shall be designed to carry the shears and moments so introduced, as well as all other forces, without exceeding at any point the unit stresses prescribed in NF-3321.1, except that some nonelastic but self-limiting deformation of a part of the connection may be permitted when this is essential to the avoidance of overstressing of fasteners.

(3) *Provision for Expansion.* Adequate provision shall be made for expansion and contraction appropriate to the function of the support structure.

NF-3322.8 Gross and Net Areas

(a) *Determination of Gross and Net Areas.* The gross area of a member at any point shall be determined by summing the products of the thickness and the gross width of each element as measured normal to the axis of the member. The net area shall be determined by substituting the net width, computed in accordance with (c) below, for the gross width.

(b) *Net Area and Effective Net Area.* Unless otherwise specified, tension members shall be designed on the basis of net area. Compression members shall be designed on the basis of gross area. Beams and girders shall be designed in accordance with NF-3322.3(a).

(c) Calculation of Net Area

(1) Parts With Holes

(a) In the case of a chain of holes extending across a part in any diagonal or zigzag line, the net width of the part shall be obtained by deducting from the gross width the sum of the diameters of all the holes in the chain and adding, for each gage space in the chain, the quantity $s^2/4g$.

(b) The critical net area A_n of the part is obtained from that chain which gives the least net width.

(c) In determining the net area across plug or slot welds, the weld metal shall not be considered as adding to the net

area.

(d) The effective net area A_e of axially loaded tension members, where the load is transmitted by bolts through some but not all of the cross-sectional elements of the member, shall be computed from the formula:

$$A_e = C_t A_n$$

Unless a larger coefficient can be justified by tests or other recognized criteria, the following values of C_t shall be used in computations:

When the load is transmitted by welds through some but not all of the cross-sectional elements of the member, the effective net area A_e shall be computed as:

$$A_e = U A_g$$

where

$$A_g = \text{gross area of member, in.}^2$$

When load is transmitted by transverse welds to some but not all of the cross-sectional elements of W, M, or S shapes and structural tees cut from these shapes, A_e shall be taken as the area of the directly connected elements.

When the load is transmitted to a plate by longitudinal welds along both edges at the end of the plate, the length of the welds shall not be less than the width of the plate. The effective net area A_e shall be computed as above.

Unless a larger coefficient can be justified by tests or other criteria, the following values of U shall be used: when $l > 2w$, $U = 1.0$; when $2w > l > 1.5w$, $U = 0.87$; when $1.5w > l > w$, $U = 0.75$

where

$$l = \text{weld length, in.}$$

$$w = \text{plate width (distance between welds), in.}$$

(1) W, M, or S shapes with flange widths not less than two-thirds of the depth, and structural tees cut from these shapes, provided the connection is to the flanges and has no fewer than three fasteners per line in the direction of applied stress:

$$C_t = 0.90$$

(2) W, M, or S shapes not meeting the conditions of (c)(1)(d)(1) above, structural tees cut from these shapes, and all other shapes, including built-up cross sections, provided the connection has not less than three fasteners per line in the direction of applied stress:

$$C_t = 0.85$$

(3) all members whose connections have only two fasteners per line in the direction of applied stress:

$$C_t = 0.75$$

(e) Bolted splice and gusset plates, and other connection fittings subject to tensile force shall be designed in accordance with the provisions of NF-3322.1(a) where the effective net area shall be taken

Page 75

as the actual net area, except that for the purpose of design calculations it shall not be taken as greater than 85% of the gross area.

(2) *Size of Bolt Holes.* In computing net area, the diameter of a bolt hole shall be taken as $1/16$ in. greater than the nominal dimension of the hole normal to the direction of applied stress.

(3) *Angles.* For angles, the gross width shall be the sum of the widths of the legs less the thickness. The gage for holes in opposite legs shall be the sum of the gages from the back of angles less the thickness.

(4) *Pin-Connected Members*

(a) Eyebars shall be of uniform thickness without reinforcement at the pinholes.¹² They shall have circular heads in

which the periphery of the head beyond the pinhole is concentric with the pinhole. The radius of transition between the circular head and the body of the eyebar shall be equal to or greater than the diameter of the head. The width of the body of the eyebar shall not exceed eight times its thickness and the thickness shall not be less than $\frac{1}{2}$ in. (13 mm). The minimum net area beyond the pin hole, parallel to the axis of the member, shall not be less than $\frac{2}{3}$ of the net area across the pin hole. The thickness may be less than $\frac{1}{2}$ in. (13 mm) only if external nuts are provided to tighten pin plates and filler plates into snug contact. The diameter of the pin shall not be less than seven-eighths of the width of the body of the eyebar. The diameter of the pinhole shall not be more than $\frac{1}{32}$ in. (0.8 mm) greater than the diameter of the pin. For steels having a yield stress greater than 70.0 ksi (480 MPa), the diameter of the pinhole shall not exceed five times the plate thickness.

(b) In pin-connected plates other than eyebars, the tensile stress on the net area transverse to the axis of the member shall not exceed the stress allowed in NF-3322.1(a), and the bearing stress on the projected area of the pin shall not exceed the stress allowed in NF-3322.1(f)(1). The minimum net area beyond the pinhole, parallel to the axis of the member, shall not be less than two-thirds of the net area across the pinhole.

12 Members having a different thickness at the pinhole location are termed built-up.

(c) The distance used in calculations, transverse to the axis of pin-connected plates or any individual element of a built-up member, from the edge of the pinhole to the edge of the member or element shall not exceed 4 times the thickness at the pinhole. For calculation purposes, the distance from the edge of the pinhole to the edge of the plate or to the edge of a separated element of a built-up member at the pinhole, shall not be assumed to be more than 0.8 times the diameter of the pinhole.

(d) The corners beyond the pinhole may be cut at 45 deg. to the axis of the member, provided the net area beyond the pinhole, on a plane perpendicular to the cut, is not less than that required beyond the pinhole parallel to the axis of the member.

(e) Thickness limitations on both eyebars and pin-connected plates may be waived whenever external nuts are provided so as to tighten pin plates and filler plates into snug contact. When the plates are thus contained, the allowable stress in bearing shall be no greater than as specified in NF-3322.1(f)(1).

NF-3323 Design Requirements for Steel Castings and Forgings

NF-3323.1 Allowable Stresses.

Allowable stresses for steel castings and forgings shall be the same as those provided in NF-3322 with the applicable values for yield strength of Table Y-1, Section II, Part D, Subpart 1.

NF-3324 Design Requirements for Connections and Joints

NF-3324.1 General Requirements

(a) *Types of Connections Permitted.* Structural Connections of a welded, bolted, or welded and bolted type shall be used.

Types of bolted connections include:

(1) Friction-type connections that are mechanically fastened structural connections that use high strength bolts (such as SA-325 and SA-490) and are sufficiently tightened to reliably produce a high clamping force that prevents slip between faying surfaces. Load is transferred at the faying surfaces by friction [Fig. NF-3324.1(a)(1)].

(2) Bearing-type connections that are mechanically fastened structural connections that depend on direct shear of the fastener to transfer the load from one connected part to another.

(3) Other connections that are not covered by (1) and (2) above, such as clamps and U-bolts shown in Fig. NF-1214-1, are not friction-type connections and shall meet the requirements of NF-3380, unless otherwise indicated in the design documents.

(b) *Provision for Eccentric Connections.* Axially stressed members meeting at a point shall have their gravity axes

GENERAL NOTES:

T = clamping force

P = applied load

F = friction force

FIG. NF-3324.1(a)(1) TYPICAL FRICTION-TYPE CONNECTIONS USING HIGH STRENGTH BOLTS

FIG. NF-3324.1(a)(1) TYPICAL FRICTION-TYPE CONNECTIONS USING HIGH STRENGTH BOLTS

(c) *Placement of Bolts and Welds.* Except as otherwise provided, groups of bolts or welds at the ends of any member transmitting axial stress into that member shall have their centers of gravity on the gravity axis of the member, unless provision is made for the effect of the resulting eccentricity. Except in members subject to repeated variation in stress, as stipulated in NF-3330, disposition of fillet welds to balance the forces about the neutral axes for end connections of single angle, double angle, and similar type members is not required. Eccentricity between the gravity axes of such members and the gage lines for their bolted end connections may be neglected in statically loaded members, but should be considered in members subjected to fatigue loading.

NF-3324.2 Connection Design

(a) *Connections for Unrestrained Members*

(1) Except as otherwise indicated by the Designer, connections of beams, girders, or trusses shall be designed as flexible and may ordinarily be proportioned for the reaction shears only.

(2) Flexible beam connections shall accommodate end rotations of unrestrained (simple) beams. To accomplish this, inelastic action in the connection is permitted.

(b) *Connections for Restrained Members*

(1) Fasteners or welds for end connections of beams, girders, and trusses shall be designed for the combined effect of forces resulting from moment and shear induced by the rigidity of the connections.

(2) When flanges or moment connection plates for end connections of beams and girders are welded to the flange of an I or H shaped column, a pair of column web stiffeners having a combined cross-sectional area A_{st} not less than that computed from Eq. (48) shall be provided whenever the calculated value of A_{st} is positive:

$$A_{st} = \frac{P_{bf} - F_{yc}t(t_b + 5k)}{F_{yst}} \quad (48)$$

(48)

(3) Notwithstanding the requirements of (b)(2) above, a stiffener or a pair of stiffeners shall be provided opposite the compression flange when the column web depth clear of fillets d_c is greater than:

$$\frac{4100t^3 \times \sqrt{F_{yc}}}{P_{bf}}$$

and a pair of stiffeners shall be provided opposite the tension flange when the thickness of the column flange t_f is less than:

$$0.4 \sqrt{(P_{bf}/F_{yc})}$$

(4) Stiffeners required by the provisions of (b)(2) and (3) above shall comply with the following criteria:

(a) The width of each stiffener plus one-half the thickness of the column web shall not be less than one-third the width of the flange or moment connection plate delivering the concentrated force.

(b) The thickness of stiffeners shall not be less than $t_b/2$.

(c) When the concentrated force delivered occurs on only one column flange, the stiffener length need not exceed one-half the column depth.

(d) The weld joining stiffeners to the column web shall be sized to carry the force in the stiffener caused by unbalanced moments on opposite sides of the column.

(5) The thickness of column webs within the boundaries of rigid connections of two or more members whose webs lie in a common plane shall not be less than

$$t_{\min} = \frac{32M}{d_b \cdot d_c \cdot S_y}$$

where

M	= the algebraic sum of clockwise and counter-clockwise moments, kip-ft, applied on opposite sides of the connection boundary
d_b	= the beam depth, in.
d_c	= the column depth, in.
$t_{\min}$	= the web thickness, in.

When the web thickness is less than $t_{\min}$ doubler plates or longitudinal stiffeners may be provided to reinforce the column web.

(c) Connections of Tension and Compression Members in Trusses. The connections at ends of the tension or compression member in trusses shall develop the force due to the Design Load but not less than 50% of the effective strength of the member, based upon the kind of stress that governs the selection of the member.

(d) Connections for Compression Members With Bearing Joints

(1) For members subjected to compression forces only, which bear on bearing plates, sufficient bolts or welds shall be provided to hold all parts securely in place.

(2) For members subjected to compression forces only, which are finished to bear at splices, the splice material and its bolting or welding shall be arranged to hold all parts in line and shall be proportioned for 50% of the computed stress.

(3) All of the foregoing joints shall be proportioned to resist any tension that would be developed by design moments acting in conjunction with 75% of the axial compression forces.

NF-3324.3 Design of Lap Joints and Fillers

(a) Lap Joint Design. The minimum amount of lap on lap joints shall be five times the thickness of the thinner part joined but not less than 1 in. (25 mm). Lap joints subjected to axial stress shall be fillet welded along the end of both lapped parts, except where the deflection of the lapped parts is sufficiently restrained to prevent opening of the joint under maximum loading.

(b) Filler Design

(1) Bolted Construction. When bolts carrying computed stress pass through fillers thicker than $\frac{1}{4}$ in., except in friction-type connections assembled with high strength bolts, the fillers shall be extended beyond the splice material and the filler extension shall be secured by enough bolts to distribute the total stress in the member uniformly over the combined section of the member and the filler or an equivalent number of fasteners shall be included in the connection. Fillers between $\frac{1}{4}$ in. (6 mm) and $\frac{3}{4}$ in. (19 mm) thick, inclusive, need not be extended and developed, provided the allowable shear stress in the bolts is reduced by the factor, $0.4(t - 0.25)$, where t is the total thickness of the fillers, up to $\frac{3}{4}$ in. (19 mm).

(2) Welded Construction. In welded construction, any filler $\frac{1}{4}$ in. (6 mm) or more in thickness shall extend beyond the edges of the splice plate and shall be welded to the part on which it is fitted with sufficient weld to transmit the splice plate stress, applied at the surface of the filler as an eccentric load. The welds joining the splice plate to the filler shall be sufficient to transmit the splice plate stress and shall be long enough to avoid overstressing the filler along the toe of the weld. Any filler less than $\frac{1}{4}$ in. (6 mm) thick shall have its edges made flush with the edges of the splice plate, and the weld size shall be the sum of the size necessary to carry the splice plate stress plus the thickness of the filler plate.

NF-3324.4 Joint Combinations

(a) Combinations of Welds. If two or more of the general types of weld (groove, fillet, plug, or slot) are combined in a single joint, the effective capacity of each shall be separately computed with reference to the axis of the group, in order to determine the allowable capacity of the combination.

(b) Bolts in Combination With Welds. SA-307 bolts or high strength bolts used in bearing-type connections shall not be considered as sharing the stress in combination with welds. Welds, if used, shall be provided to carry the entire stress in the connection. High strength bolts installed as a friction-type connection prior to welding may be considered as sharing the stress with the welds.

NF-3324.5 Design of Welded Joints

(a) Permissible Types of Welded Joints in Linear Supports. All welded joints in Linear Supports shall be as described in NF-3256.1 except that intermittent or lap joints using fillet welds may not be used for the support of Class 1 Components or Class 2 vessels designed to NC-3200. The allowable stress limits shall be as defined in (b) and (c) below.

(b) Design Limits. The allowable stress limits which must be satisfied for welds for Design Loadings stated in the Design Specification shall be as follows.

(1) Full Penetration Groove Welds. The stress limits for full penetration groove welds shall not exceed the applicable stress value for the base metal being joined, as specified in NF-3321.1 and Table NF-3324.5(a)-1.

(2) Partial Penetration Groove Welds

**TABLE NF-3324.5(a)-1
ALLOWABLE STRESS LIMITS FOR CLASS 1 LINEAR-TYPE SUPPORT WELDS**

Kind of Stress	Base Metal TS Range, ksi	Weld Metal Min. TS, ksi [Note (1)]	Stress Limits, ksi
Tension and compression parallel to axis of any full penetration groove weld	...	...	Same as for base metal
Tension normal to effective throat of full penetration groove weld	...	...	Same as allowable tensile stress for base metal
Compression normal to effective throat of full penetration groove weld and partial penetration groove weld	...	...	Same as allowable compressive stress for base metal
Shear stress on effective throat of fillet weld, regardless of direction of application of load; tension normal to the axis on the effective throat of a partial penetration groove weld and shear stress on effective area of a plug or slot weld. The given stresses shall also apply to such welds made with the specified electrode on steel having a yield stress greater than that of the matching base metal.	45–60	60	0.30 × minimum tensile strength of weld metal (ksi), except shear stress on base metal shall not exceed 0.40 × yield stress of base metal
	61–70	70	
	71–80	80	
	81–90	90	
	91–100	100	
	101–120	120	

NOTE:

(1) Weld metal one nominal strength level stronger than shown will be permitted (e.g., E70xx for E60xx applications).

TABLE NF-3324.5(a)-1 ALLOWABLE STRESS LIMITS FOR CLASS 1 LINEAR-TYPE SUPPORT WELDS

(a) *Compression Normal to Effective Throat or Shear on Effective Throat.* The stress limits shall be the same as those for the base metal, as required by NF-3321.1.

(b) *Tension Normal to the Axis on the Effective Throat.* The stress limits shall be as specified in Table NF-3324.5(a)-1.

(3) *Fillet Welds.* The allowable stress limits for fillet welds shall be as specified in Table NF-3324.5(a)-1.

(c) *Service Limits, Level A Through D, and Test.* The rules and stress limits which must be satisfied for welds for any Level A through D Service and Test Loading stated in the Design Specification are those given in NF-3324.5(b) multiplied by the appropriate base material stress limit factor given in Table NF-3623(b)-1 for piping supports and Table NF-3523(b)-1 for component supports.

(d) *Fillet Welds*

(1) *Minimum Size of Fillet Welds and Partial Penetration Welds.* Fillet and partial penetration welds shall not be specified less than $\frac{1}{8}$ in. (3.2 mm) (NF-4427). When fillet or partial penetration welds less than $\frac{1}{4}$ in. (6 mm) are used to join heavy section members, the designer shall consider specifying preheat and special requirements for fit-up of members to ensure adequate weld deposition.

(2) *Maximum Effective Size of Fillet Welds.* The maximum size of a fillet weld that may be assumed in the design of a connection shall be such that the stresses in the adjacent base material do not exceed the values allowed in Table NF-3324.5(a)-1 and NF.3321.1. The maximum size that may be used along edges of connected parts shall be as stipulated in (d)(2)(a) and (b) below:

(a) along edges of material less than $\frac{1}{4}$ in. (6 mm) thick, the maximum size may be equal to the thickness of the material;

(b) along edges of material $\frac{1}{4}$ in. (6 mm) or more in thickness, the maximum size shall be $\frac{1}{16}$ in. (1.6 mm) less than the thickness of the material, unless the weld is especially designated on the drawings to be built up to obtain full throat thickness.

(3) Length of Fillet Welds

Page 79

(a) The effective length of a fillet weld shall be the overall length of a full-size fillet, including returns.

(b) The minimum effective length of a strength fillet weld shall be not less than four times the nominal size, or else the size of the weld shall be considered not to exceed one-fourth of its effective length.

(c) If longitudinal fillet welds are used alone in end connections of tension members, the length of each fillet weld shall be not less than the perpendicular distance between them. The transverse spacing of longitudinal fillet welds used in end connections shall not exceed 8 in., unless the design otherwise prevents excessive transverse bending in the connection.

(4) *Effective Throat Thickness of Fillet Welds.* The effective throat thickness of a fillet weld joining members at angles between 60 deg. and 135 deg., inclusive (Fig. NF-4427-1), shall be the shortest distance from the root to the face of the diagrammatic weld, except that for fillet welds made by the submerged arc process the effective throat thickness shall be taken equal to the leg size for $\frac{3}{8}$ in. (10 mm) and smaller fillet welds, and equal to the theoretical throat plus 0.11 in. for fillet welds over $\frac{3}{8}$ in. (10 mm). For fillet welds joining members at angles less than 60 deg. use the rules for partial penetration groove welds, NF-3324.5(f)(3).

(5) *Effective Area of Fillet Welds.* The effective area of fillet welds shall be considered as the effective length of the weld times the effective throat thickness.

(6) *Effective Area of Fillet Welds in Holes and Slots.* The effective area of fillet welds in holes and slots shall be computed as specified in (d)(5) above for fillet welds using for effective length the length of center line of the weld through the center of the plane through the throat. However, in the case of overlapping fillets the effective area shall not exceed the nominal cross-sectional area of the hole or slot in the plane of the faying surface.

(7) *Intermittent Fillet Welds.* Intermittent fillet welds may be used to transfer calculated stresses across a joint or faying surface, when the strength required is less than that developed by a continuous fillet weld of the smallest permitted size, and to join elements of built-up members. The effective length of any segment of intermittent fillet welding shall not be less than four times the weld size with a minimum of $1\frac{1}{2}$ in. (38 mm).

(8) *End Returns to Fillet Welds.* Side or end fillet welds terminating at ends or sides, respectively, of parts or members shall, when required by the designer, be returned continuously around the corners for a distance not less than twice the nominal size of the weld. This provision shall apply to side and top fillet welds connecting brackets, beam seats, and similar connections, on the plane about which bending moments are computed. For framing angles and simple end-plate connections which depend upon flexibility of the outstanding legs for connection flexibility, end returns shall not exceed four times the nominal size of the weld. Fillet welds which occur on opposite sides of a common plane shall be interrupted at the corner common to both welds. End returns, when required by the designer, shall be indicated on the drawings.

(9) *Fillet Welds in Holes and Slots.* Fillet welds in holes or slots may be used to transmit shear in lap joints or to prevent the buckling or separation of lapped parts and to join elements of built-up members. Such fillet welds may overlap, subject to the provisions of (d)(6) above. Fillet welds in holes or slots are not to be considered plug or slot welds.

(e) Plug and Slot Welds

(1) *Use of Plug and Slot Welds.* Plug and slot welds may be used to transmit shear in a lap joint or to prevent buckling of lapped parts and to join component parts of built-up members.

(2) *Diameter of Holes for Plug Welds.* The diameter of the holes for a plug weld shall be not less than the thickness of the part containing it plus $\frac{5}{16}$ in. (8 mm), rounded to the next greater odd $\frac{1}{16}$ in. (1.6 mm), nor greater than the minimum diameter plus $\frac{1}{8}$ in. (3.2 mm) or $2\frac{1}{4}$ times the thickness of the weld metal.

(3) *Spacing of Plug Welds.* The minimum center-to-center spacing of plug welds shall be four times the diameter of the hole.

(4) *Length of Slot Welds.* The length of slot for a slot weld shall not exceed 10 times the thickness of the weld. The width of the slot shall be not less than the thickness of the part containing it plus $\frac{5}{16}$ in. (8 mm), rounded to the next greater odd $\frac{1}{16}$ in. (1.6 mm), nor shall it be greater than $2\frac{1}{4}$ times the thickness of the weld. The ends of the slot shall be semicircular or shall have the corners rounded to a radius not less than the thickness of the part containing it, except for those ends which extend to the edge of the part.

(5) *Spacing of Slot Welds.* The minimum spacing of lines of slot welds in a direction transverse to their length shall be four times the width of the slot. The minimum center to center spacing in a longitudinal direction on any line shall be two times the length of the slot.

(6) *Thickness of Plug and Slot Welds.* The thickness of plug and slot welds in material $\frac{5}{8}$ in. (16 mm) or less in thickness shall be equal to the thickness of the material. In material over $\frac{5}{8}$ in. (16 mm) in thickness, it shall be at least one-half the thickness of the material but not less than $\frac{5}{8}$ in. (16 mm).

Page 80

(7) *Effective Shearing Area of Plug and Slot Welds.* The effective shearing area of plug and slot welds shall be considered as the nominal cross-sectional area of the hole or slot in the plane of the faying surface.

(f) *Full Penetration and Partial Penetration Joints.* The effective area shall be the effective weld length multiplied by the effective throat thickness.

(1) The effective weld length for any groove weld, square or skewed, shall be the length of weld throughout which the correct proportioned cross section exists. In a curved weld it shall be its true length measured along its curvature.

(2) The effective throat thickness of a full penetration groove weld which shall conform to the requirements of NF-4000 shall be the thickness of the thinner part joined. No increase is permitted for weld reinforcement.

(3) The effective throat of partial penetration groove welds is dependent upon the type of groove.

(a) For square, U, and J groove welds, the effective throat is equal to the depth of preparations.

(b) For V and bevel groove welds with an included angle at the root equal to or greater than 60 deg., the effective throat shall be the minimum distance from the root to the face of the weld.

(c) For V and bevel groove welds with an included angle at the root less than 60 deg. but equal to or greater than 45 deg., the effective throat shall be the minimum distance from the root to the face of the weld less $\frac{1}{8}$ in. (3.2 mm).

(d) For V and bevel groove welds, with an included angle at the root less than 45 deg. but equal to or greater than 30 deg., the effective throat shall be the minimum distance from the root to the face of the weld less $\frac{1}{8}$ in. (3.2 mm) and multiplied by 0.75. The required effective throat must be specified on the drawing.

(e) For V and bevel groove welds, angles less than 30 deg. at the root are not allowed.

(f) For flare bevel groove welds, when filled flush to the surface, the effective throat shall be 0.31 times the outside radius of the curved section forming the groove. For formed rectangular tubing, the outside radius may be considered as two times the wall thickness.

(g) For flare V groove welds, when filled flush to the surface, the effective throat shall be 0.5 (except use 0.375 for GMAW when $R \geq \frac{1}{2}$ in. (13 mm) times the outside radius when the outside radius is less than 1 in. For flare bevel groove welds, the effective throat shall be 0.312 times the outside radius.

NF-3324.6 Design Requirements for Bolted Joints.

The rules and stress limits for bolting shall be as given in this paragraph. The stress limits which must be satisfied for

any Design, Level A through D, and Test Loadings, shall be those given in this paragraph, multiplied by the appropriate stress limit factors given in Table NF-3225.2-1 for the particular Loading specified in the Design Specification (NCA-3250). This product shall not exceed the yield strength of the material at temperature.

(a) *Allowable Stresses.* Allowable tensile, shearing, and bearing stresses in bolts and threaded parts shall be as given in the paragraphs below. All allowables are expressed in ksi acting on the actual bolt area available in the shear planes of the connected parts. All are expressed in terms of the ultimate tensile strength at temperature (Table Y-1, Section II, Part D, Subpart 2). The shear capacity of bolts is directly proportional to the shear area available in the shear planes. Shear strength is unaffected by shear plane location.

(1) *Tensile Stress Only.* Bolts loaded in direct tension shall be so proportioned that their average tensile stress F_{tb} , computed on the basis of the actual tensile stress area available (independent of any initial tightening force), shall not exceed:

For ferritic steels:

$$F_{tb} = \frac{S_u}{2}$$

For austenitic steels:

$$F_{tb} = \frac{S_u}{3.33}$$

The applied load shall be the sum of the external load and any tension resulting from prying action produced by

deformation of the connected parts.

(2) *Shearing Stress Only*

(a) *Bearing-Type Joints*

(1) *Threads Excluded From Shear Planes.* The allowable shear F_{vb} in bolts and threaded parts loaded in direct shear, expressed in ksi of actual shear stress area available (applicable to the total nominal bolt area in the shear planes in this case), shall not exceed:

Page 81

For ferritic steels:

$$F_{vb} = \frac{0.62S_u}{3}$$

For austenitic steels:

$$F_{vb} = \frac{0.62S_u}{5}$$

(2) *Threads Not Excluded From Shear Planes.* The allowable shear stress F_{vb} in bolts and threaded parts loaded in direct shear, expressed in ksi of actual shear stress area available (applicable to the total bolt root area in the shear planes in this case), shall not exceed:

For ferritic steels:

$$F_{vb} = \frac{0.62S_u}{3}$$

For austenitic steels:

$$F_{vb} = \frac{0.62S_u}{5}$$

(3) Combined Tensile and Shear Stresses

(a) Bearing-Type Joints. Bolts subjected to combined shear and tension shall be so proportioned that either the shear or the tensile stress, kips/sq in. of actual cross-sectional area, shall not exceed the value derived from the ellipse equation below when the corresponding computed tensile or shearing stress is substituted:

$$\frac{f_i^2}{F_{ib}^2} + \frac{f_v^2}{F_{vb}^2} = 1$$

The allowable tensile and shear stress values shall be those derived from the equations given in (a)(1) and (2) above.

(b) *Friction-Type Joints.* A bolt in a connection designed as a friction-type joint is not subjected to shear (provided the joint does not slip into bearing); it experiences tension only. Friction-type joints shall be designed as given in (a)(4) below.

(4) *Slip Resistance - Friction-Type Joints.* The maximum slip resistance to which a friction-type joint may be designed shall not exceed the value of P_s , calculated in the following equation [see Table NF-3324.6(a)(4)-1]:

$$P_s = mnT_i k_s$$

**TABLE NF-3324.6(a)(4)-1
EFFECTIVE SLIP COEFFICIENT VS
SURFACE CONDITION**

Surface Condition	Slip Coefficient, k_s
Clean mill scale	0.25
Grit-blasted carbon and low alloy high strength steel	0.41
Grit-blasted heat treated steel	0.25
Hot dip galvanized wire, brushed, scored, or blasted	0.31
Blast cleaned, zinc rich paint	0.31
Blast cleaned, zinc silicate paint	0.45

TABLE NF-3324.6(a)(4)-1 EFFECTIVE SLIP COEFFICIENT VS SURFACE CONDITION

If the joint clamping force will be reduced by any direct tension load on the joint, the T_i value shall be reduced by an equivalent amount before substituting in the above equation. SA-307 and austenitic steel bolting shall not be used for friction-type joints.

(5) *Bearing Stress.* Allowable bearing stress on the projected area of bolts in bearing type connections shall be:

$$F_p = \frac{LS_u}{2d} \leq 1.5S_u$$

(b) Minimum Edge Distance

(1) Minimum Edge Distance in Line of Load. In both bearing- and friction-type joints the minimum distance from the center of the end bolt in a connection to that edge of the connected part toward which the load is directed shall be determined in accordance with either (b)(1)(a) or (b) below.

(a) The edge distance shall satisfy all of the following:

(1) $L/d \geq 0.5 + 1.43 (f_p/S_u)$

(2) $L/d \geq 1.2$

(3) $f_p/S_u \leq 1.5$

where

$$f_p = P/dt$$

(b) The edge distance shall be as shown in Table NF-3324.6(b)(1)-1.

(c) Maximum Edge Distance. The maximum distance from the center of any rivet or bolt to the nearest edge of parts in contact shall be 12 times the thickness of the connected part under consideration, but shall not exceed 6 in. Bolted joints in unpainted steel exposed

to atmospheric corrosion require special limitations on pitch and edge distance.

**TABLE NF-3324.6(b)(1)-1
MINIMUM EDGE DISTANCES**

Minimum Edge Distance for Punched, Reamed, or Drilled Holes, in.		
Bolt Diameter, in.	At Sheared Edges	At Rolled Edges of Plates, Shapes, or Bars, or Gas Cut Edges [Note (1)]
$\frac{1}{2}$	$\frac{7}{8}$	$\frac{3}{4}$
$\frac{5}{8}$	$1\frac{1}{8}$	$\frac{7}{8}$
$\frac{3}{4}$	$1\frac{1}{4}$	1
$\frac{7}{8}$	$1\frac{1}{2}$ [Note (2)]	$1\frac{1}{8}$
1	$1\frac{3}{4}$ [Note (2)]	$1\frac{1}{4}$
$1\frac{1}{8}$	2	$1\frac{1}{2}$
$1\frac{1}{4}$	$2\frac{1}{4}$	$1\frac{5}{8}$
$>1\frac{1}{4}$	$1\frac{3}{4} \times \text{diam.}$	$1\frac{1}{4} \times \text{diam.}$

NOTES:

- (1) All edge distances in this column may be reduced $\frac{1}{8}$ in. when the hole is at the point where stress does not exceed 25% of the maximum allowed stress in the element.
- (2) These may be $1\frac{1}{4}$ in. at the ends of beam connection angles.

TABLE NF-3324.6(b)(1)-1 MINIMUM EDGE DISTANCES

For unpainted, built-up members made of weathering steel which will be exposed to atmospheric corrosion, the spacing of fasteners connecting a plate and a shape or two-plate components in contact shall not exceed 14 times the thickness of the thinnest part nor 7 in. (178 mm), and the maximum edge distance shall not exceed eight times the thickness of the thinnest part, or 5 in. (127 mm).

(d) *Minimum Spacing.* The distance between centers of standard, oversized, or slotted fastener holes shall be not less than three times the nominal diameter of the bolt. Along a line of transmitted force, the distance between centers of holes shall be not less than the following:

$$\text{Standard Holes: } 2P/S_u t + d/2$$

(e) *Effective Bearing Area.* The effective bearing area of bolts shall be the diameter multiplied by the length in bearing,

except that for countersunk bolts one-half the depth of the countersink shall be deducted.

(f) *Long Grips.* SA-307 bolts, which carry calculated stress and the grip of which exceeds five diameters, shall have their number increased 1% for each additional $\frac{1}{16}$ in. (1.6 mm) in the grip.

(g) *Anchor Bolts.* Anchor bolts shall be designed to provide resistance to all conditions of tension and shear at the bases of columns, including the net tensile components of any bending moments which may result from fixation or partial fixation of columns.

NF-3324.7 Design Requirements for Column Bases.

Proper provision shall be made to transfer the column loads and moments, if any, to the footings and foundations.

NF-3330 HIGH CYCLE FATIGUE DESIGN FOR CLASS 1

NF-3331 Introduction

NF-3331.1 Scope.

Members and their connections, subject to a number of cycles (>20,000) of fatigue loading resulting in damage as defined in NF-3331.2, shall be proportioned to satisfy the stress range limitations provided therein.

NF-3331.2 Definitions.

High cycle fatigue, as used in this Subsubarticle, is defined as the damage that may result in fracture after a sufficient number of fluctuations of stress. *Stress range* is defined as the numerical sum of maximum repeated tensile and compressive stresses or the sum of maximum shearing stresses of opposite direction at a given point, resulting from differing arrangements of live load.

NF-3332 Design Requirements

NF-3332.1 Design Considerations.

In the design of members and connections subject to repeated variation of live load stress, consideration shall be given to the number of stress cycles, the expected range of stress, and the type and location of member or detail.

NF-3332.2 Classification of Loading Conditions.

Loading conditions shall be classified as shown in Table NF-3332.2-1.

NF-3332.3 Stress Categories.

Stress categories for use in establishing the maximum range of stress in relation to the type of member or part, material, and location shall be as stipulated in Table NF-3332.3-1. For illustrations of the members and parts, see Fig. NF-3332.3-1.

NF-3332.4 Allowable Stresses.

The maximum stress shall not exceed the basic allowable stress permitted by NF-3322 and the maximum range of stress shall not exceed that given in Table NF-3332.4-1.

NF-3332.5 Provisions for Mechanical Fasteners.

Range in tensile stress in properly tightened ASTM A325 or ASTM A490 bolts need not be considered, but the maximum computed stress, including prying action, shall not exceed the values given in NF-3332.4 subject to the following stipulations.

TABLE NF-3332.2-1
CLASSIFICATION OF LOADING CONDITIONS

Loading Condition	Number of Loading Cycles	
	From	To
1	20,000 [Note (1)]	100,000 [Note (2)]
2	100,000	500,000 [Note (3)]
3	500,000	2,000,000 [Note (4)]
4	> 2,000,000	

NOTES:

- (1) Approximately equivalent to 2 applications every day for 25 years.
- (2) Approximately equivalent to 10 applications every day for 25 years.
- (3) Approximately equivalent to 50 applications every day for 25 years.
- (4) Approximately equivalent to 200 applications every day for 25 years.

TABLE NF-3332.2-1 CLASSIFICATION OF LOADING CONDITIONS

(a) Connections subject to more than 20,000 cycles, but not more than 500,000 cycles of direct tension may be designed for the stress produced by the sum of applied and prying loads if the prying load does not exceed 10% of the externally applied load. If the prying force exceeds 10%, the allowable tensile stress given in NF-3324.6(a)(1) shall be reduced 40%, applicable to the external load alone.

(b) Connections subject to more than 500,000 cycles of direct tension may be designed for the stress produced by the sum of applied and prying loads if the prying load does not exceed 5% of the externally applied load. If the prying force exceeds 5%, the allowable tensile stress given in NF-3324.6(a)(1) shall be reduced 50%, applicable to the external load alone. The use of other bolts and threaded parts subject to tensile fatigue loading is not recommended. Bolts and threaded parts subjected to cyclic loading in shear may be designed for the bearing-type shear stresses given in NF-3324.6(a)(2) insofar as the fatigue strength of the fasteners is concerned.

NF-3340 LIMIT ANALYSIS DESIGN FOR CLASS 1

NF-3341 Introduction

NF-3341.1 Scope

(a) Subject to the limitation of this Subsubarticle, simple or continuous beams, rigid frames, and similar portions of structures rigidly constructed so as to be continuous over at least one interior support¹³ may be proportioned on the basis of plastic design, namely, on the basis of low bound collapse load. This strength, as determined by rational analysis, shall not be less than that required to support a factored load equal to 1.7 times those of the level A and Level B Service Limits or 1.3 times that of the Level C Service Limits.

(b) Connections joining a portion of a structure designed on the basis of plastic behavior with a portion not so designed need be no more rigid than ordinary seat and cap angle or ordinary web connections.

(c) When plastic design is used as the basis for proportioning continuous beams and structural frames, the provisions relating to allowable working stress contained in NF-3320 are waived. Except as modified by these rules, all other provisions of NF-3320 shall govern.

NF-3342 Design Requirements

NF-3342.1 General Design Requirements

(a) *Shear.* Unless reinforced by diagonal stiffeners or a doubler plate, the webs of column, beams, and girders, including areas within the boundaries of the connections, shall be so proportioned that:

$$(1) V_u \leq 0.555 S_y t d$$

where V_u is the shear, kips, that would be produced by the required factored loading.

(b) *Combined Loads.* When the interaction method of calculation (Section III, Division 1, Appendices, A-9000) is used, members shall be so proportioned that the interaction of factored loads at a section shall satisfy the interaction equations of Table A-9210(d)-1 (Section III, Division 1, Appendices), except that columns subjected to combined bending and compression shall be governed by the requirements of NF-3342.2(b)(3).

(c) *Depth-Thickness Ratio of Webs.* The depth-thickness ratio of webs of members subjected to plastic bending shall not exceed the value given by Eqs. (2) and (3), as applicable:

¹³ As used here, interior support may be taken to include a rigid frame knee formed by the junction of a column and a sloping or horizontal beam or girder.

**TABLE NF-3332.3-1
STRESS CATEGORIES**

General Condition	Situation	Kind of Stress [Note (1)]	Stress Category (See Table NF-3332.4-1)	Illustrative Example [Note (2)] Sketch Nos. (See Fig. NF-3332.3-1)
Plain material	Base metal with rolled or cleaned surfaces	T or Rev.	A	(1), (2)
Built-up members	Base metal and weld metal in members, without attachments, built up plates or shapes connected by continuous full or partial penetration groove welds, or continuous fillet welds parallel to the direction of applied stress	T or Rev.	B	(3), (4), (5), (6)
	Base metal in members without attachments, built-up plates or shapes connected by continuous full-penetration groove welds or by continuous fillet welds parallel to the direction of applied stress	T or Rev.	B	(3), (4), (5), (6)
	Calculated flexural stress f_b in base metal at toe of welds on girder webs or flanges adjacent to welded transverse stiffeners	T or Rev.	C	(7)
	Base metal at ends of partial length welded cover plates narrower than the flange having square or tapered ends, with or without welds across the ends or wider than flange with welds across the ends Flange thickness ≤ 0.8 in. Flange thickness > 0.8 in.	T or Rev. T or Rev.	E E'	(5) (5)
	Base metal at end of partial length welded cover plates wider than the flange without welds across the ends		E'	(5)
Mechanically fastened connections	Base metal at gross section of high-strength bolted slip-critical connections, except axially loaded joints which induce out-of-plane bending in connected material	T or Rev.	B	(8)
	Base metal at net section of other mechanically fastened joints [Note (3)]	T or Rev.	D	(8), (9)
	Base metal at net section of fully tensioned high-strength, bolted-bearing connections	T or Rev.	B	(8), (9)
Fillet welded connections	Base metal at intermittent fillet welds	T or Rev.	E	
	Base metal at junction of axially loaded members with fillet-welded end connections. Welds shall be disposed about the axis of the member so as to balance weld stresses $b \leq 1$ in. $b > 1$ in.	T or Rev. T or Rev.	E E'	(17), (18) (17), (18)

Attachments (cont'd)	Base metal at detail attached by fillet welds or partial-penetration groove welds subject to longitudinal loading $a \leq 2$ in. $2 \text{ in.} < a \leq 12b \text{ or } 4 \text{ in.}$ $a > 12b \text{ or } 4 \text{ in. when } b \leq 1 \text{ in.}$ $a > 12b \text{ or } 4 \text{ in. when } b > 1 \text{ in.}$	T or Rev. T or Rev. T or Rev. T or Rev.	C D E E'	(15), (23), (24), (25), (26) (15), (23), (24), (26) (15), (23), (24), (26) (15), (23), (24), (26)
	Base metal attached by fillet welds or partial-penetration groove welds subjected to longitudinal loading when the weld termination embodies a transition radius with the weld termination ground smooth: $R > 2$ in. $R \leq 2$ in.	T or Rev. T or Rev.	D E	(19) (19)
	Fillet-welded attachments where the weld termination embodies a transition radius, weld termination ground smooth, and main material subject to longitudinal loading: Detail base metal for transverse loading: $R > 2$ in. $R \leq 2$ in.	T or Rev. T or Rev.	D E	(19) (19)
	Base metal at stud-type shear connector attached by fillet weld or automatic end weld	T or Rev.	C	(22)
	Shear stress on nominal area of stud-type shear connectors	S	F	

NOTES:

- (1) T signifies range in tensile stress only; Rev. signifies a range involving reversal of tensile or compressive stress; S signifies range in shear, including shear stress reversal.
- (2) These examples are provided as guidelines and are not intended to exclude other reasonably similar situations.
- (3) When stress reversal is involved, use of SA-307 bolts is not recommended.
- (4) Allowable fatigue stress range for transverse partial penetration and transverse fillet welds is a function of the effective throat, depth of penetration and plate thickness. See Frank and Fisher, "Fatigue Strength of Fillet Welded Cruciform Joints," Journal of the Structural Division, ASCE, Vol. 105, No. 519, 1979.

TABLE NF-3332.4-1
ALLOWABLE STRESS RANGES

Stress Category Used in Table NF-3332.3-1	Allowable Range of Stress F_{sr} , ksi			
	Loading Condition 1 F_{sr1}	Loading Condition 2 F_{sr2}	Loading Condition 3 F_{sr3}	Loading Condition 4 F_{sr4}
A	63	37	24	24
B	49	29	18	16
B'	39	23	15	12
C	35	21	13	10 ¹
D	28	16	10	7
E	22	13	8	5
E'	16	9	6	3
F	15	12	9	8

NOTE:

(1) Flexural stress range of 12 ksi permitted at toe of stiffener welds on webs or flanges.

TABLE NF-3332.4-1 ALLOWABLE STRESS RANGES

(d) *Web Crippling.* Web stiffeners are required on a member at a point of load application where a plastic hinge would form. At points on a member where the concentrated load delivered by the flanges of a member framing into it would produce web crippling opposite the compression flange or high tensile stress in the tension flange, web stiffeners are required in accordance with the provisions of NF-3324.2(b).

(e) *Width-Thickness Ratios of Flanges*

(1) The width-thickness ratio for flanges of rolled W shapes and similar built-up single web shapes that would be subjected to compression involving hinge rotation under ultimate loading shall not exceed the following values:

$$S_y \quad b_f / 2t_f$$

	8.5
42	8.0
45	7.4
50	7.0
55	6.6
60	6.3
65	6.0

The thickness of sloping flanges may be taken as their average thickness.

(2) The width-thickness ratio of similarly compressed flange plates in box sections and cover plates shall not exceed $190/\sqrt{S_y}$. For this purpose the width of a cover plate shall be taken as the distance between longitudinal lines of connecting high strength bolts or welds.

NF-3342.2 Specific Design Requirements

(a) *Beams*. The maximum bending strength of a flexural member shall be:

$$(4) M_p = S_y Z_x$$

(b) *Columns*

(1) In the plane of bending of columns which would develop a plastic hinge at ultimate loading, the slenderness ratio l/r shall not exceed C_c defined in NF-3322.1(c).

(2) The maximum strength of an axially loaded compression member shall be taken as:

$$(5) P_{cr} = 1.7AF_a$$

where A is the gross area of the member, and F_a as defined by Eq. (4) in NF-3322.1(c)(1), is based upon the applicable slenderness ratio.

(3) Members subject to combined axial load and bending moment, including moment resulting in secondary stress, shall be proportioned so as to satisfy the following interaction formulas:

Page 91

$$\frac{P}{P_{cr}} + \frac{C_m M}{[1 - (P/P_e)] M_m} \leq 1.0 \quad (6)$$

$$\frac{P}{P_y} + \frac{M}{1.18 M_p} \leq 1.0; M \leq M_p \quad (7)$$

(6 - 7)

where

$$P_e = 1.92AF_e' \text{ where } F_e' \text{ is defined in NF-3322.1(e)}$$

$$C_m = \text{coefficient defined in NF-3322.1(e)}$$

The right-hand side of Eq. (7) may be replaced by 1.5 when it can be shown that the bending moment results only in secondary stress.

(4) For columns braced in the weak direction:

$$M_m = M_p$$

(5) For columns unbraced in the weak direction:

$$M_m = M_p \left[1.07 - \frac{(l/r_y) \sqrt{S_y}}{3160} \right] \leq M_p \quad (8)$$

(8)

(c) *Basis for Maximum Strength Determination.* For one or two story frames, the maximum strength may be determined by a routine plastic analysis procedure, and the frame instability effect $P\Delta$ may be ignored. For braced multistory frames, provisions should be made to include the frame instability effect in the design of the bracing system and frame members. For unbraced multistory frames, the frame instability effect should be included directly in the calculations for maximum strength. The vertical bracing system for a plastically designed braced multistory frame shall be shown to be adequate, as determined by a rational analysis, to prevent buckling of the structure under factored gravity load, and maintain the lateral stability of the structure, including consideration of the overturning effects of drift, under factored horizontal and gravity loads.

(1) *Stability of Braced Frames.* The vertical bracing system may be considered to function together with in-plane shear-resisting exterior and interior walls, floor slabs, and roof decks, if these walls, slabs, and decks are secured to the structural frames. The columns, girders, beams, and diagonal members, when used as the vertical bracing systems, may be considered to comprise a cantilever, simply connected truss in the analysis for frame buckling and lateral stability. Axial deformation of all members in the vertical bracing system shall be included in the lateral stability analysis. The axial force in these members, caused by factored horizontal and gravity loads, shall not exceed $0.85P_y$, where P_y is the product of yield stress times area of the member. Girders and beams included in the vertical bracing system of a braced multistory frame shall be proportioned for axial force and moment caused by the concurrent factored horizontal and gravity loads, in accordance with Eq. (5) with P_{cr} taken as the maximum axial strength of the beam, based on the actual slenderness ratio between braced points in the plane of bending.

(2) *Stability of Unbraced Frames.* The strength of an unbraced multistory frame shall be determined by a rational analysis which includes the effects of frame instability and column axial deformation. Such a frame shall be designed to be stable under the following conditions:

(a) factored gravity loads;

(b) factored gravity plus factored horizontal loads.

The axial force in the column at factored load levels shall not exceed $0.75P_y$.

(d) *Lateral Bracing*

(1) Members shall be adequately braced to resist lateral and torsional displacements at the plastic hinge locations

associated with the failure mechanism. The laterally unsupported distance l_{cr} from such braced hinge locations to similarly braced adjacent points on the member or frame shall not exceed the value determined from Eq. (9) or (10), as applicable:

$$(9) l_{cr}/r_y = 1375/S_y + 25$$

when

$$+1.0 > M'/M_p > -0.5$$

or

$$(10) l_{cr}/r_y = 1375/S_y$$

when

$$-0.5 \geq M'/M_p > -1.0$$

where

M'/M_p = the end moment ratio, positive when the segment is bent in reverse curvature and negative when bent in single curvature

(2) The provisions of (d)(1) above need not apply in the region of the last hinge to form, in the failure mechanism assumed as the basis for proportioning a given member, nor in members oriented with their weak axis normal to the plane of bending. However,

Page 92

in the region of the last hinge to form and in regions not adjacent to a plastic hinge, the maximum distance between points of lateral support shall be such as to satisfy the requirements of Eq. (17), (18), or (19) of NF-3322.1(d)(5), or Eq. (20) or (21) of NF-3322.1(e)(1). For this case, the value of f_a and f_b shall be computed from the moment and axial force at factored loading, divided by the applicable load factor.

(3) Members built into a masonry wall and having their web perpendicular to this wall can be assumed to be laterally supported with respect to their weak axis of bending.

(e) Connections

(1) *General Requirements.* All connections, the rigidity of which is essential to the continuity assumed as the basis for the analysis, shall be capable of resisting the moments, shears, and axial loads to which they would be subjected by the full factored loading, or any probable partial distribution thereof.

(2) *Corner Connections.* Corner connections (haunches) that are tapered or curved for architectural reasons shall be so proportioned that the full plastic bending strength of the section adjacent to the connection can be developed, if required.

(3) *Stiffeners.* Stiffeners shall be used, as required, to preserve the flange continuity of interrupted members at their junction with other members in a continuous frame. Such stiffeners shall be placed in pairs on opposite sides of the web of the member which extends continuously through the joint.

(4) *Stress in Bolts and Welds.* High strength bolts, SA-307 bolts, and welds shall be proportioned to resist the forces produced at factored load, using stresses equal to 1.7 times those given in NF-3324.6(a) for bolts and Table NF-3324.5(a)-1 for welds. In general, groove welds are preferable to fillet welds, but their use is not mandatory.

(5) *Joints With Painted Contact Surfaces.* High strength bolts may be used in joints having painted contact surfaces when these joints are of such size that the slip required to produce bearing would not interfere with the formation, at factored loading, of the plastic hinges assumed in the design.

NF-3350 DESIGN BY ANALYSIS FOR CLASS 2 AND MC

The design by analysis of Class 2 and MC supports shall be in accordance with NF-3320, NF-3330, and NF-3340.

NF-3360 DESIGN BY ANALYSIS FOR CLASS 3

The design by analysis of Class 3 supports shall be in accordance with NF-3320, NF-3330, and NF-3340.

NF-3370 EXPERIMENTAL STRESS ANALYSIS

Supports of all types may be designed by experimental stress analysis in accordance with Appendix II of Section III, Division 1, Appendices.

NF-3380 DESIGN BY LOAD RATING

NF-3381 Procedure for Load Rating

The procedure for load rating shall consist of imposing a total load on one or more duplicate full-size samples for a support equal to or less than the load under which the support fails to perform its required function. Full-size samples composed of various parts may have each part or a number of parts load rated provided that all parts in the load path are either load rated or otherwise qualified per NF-3300 or by experimental stress analysis. When parts are connected by bolting or welding, the connection shall be either load rated or qualified per NF-3225 or NF-3226. Should more than one part be load rated in a single load test, then the load rating equations of NF-3380 shall be evaluated for each part using the part's $S_{y(act)}$ and $S_{u(act)}$ values. The part having the lowest load rating shall establish the load rating for the combination of parts. A single test sample is permitted, but in that case, the load ratings shall be decreased by 10%. Otherwise, tests shall be run on a statistically significant number of samples. The permissible types of welded joints shall be as permitted for the specific class of construction in NF-3226.1, NF-3256.1, NF-3266, and NF-3324. The requirements of NF-3324.5(b) for size of fillet and partial penetration welds do not apply, provided the full-size sample is fabricated for testing using the minimum weld stipulated in the Design Drawings. Bolted joints in the test sample shall be made up using the lowest strength bolt material and minimum edge distance allowed by the specification.

NF-3382 Load Ratings in Relation to Design Service and Test Loadings

The load rating for Design Loadings shall be determined in accordance with the requirements for Service Level A limits. The load ratings for Service Loadings

Page 93

for which Level A, B, or C Limits have been designated shall be determined by means of the equations in the following subparagraphs. For Level D Limits, see Appendix F of Section III, Division 1, Appendices. The load rating for Test Loadings shall be determined in accordance with the requirements for Service Level B limits.

NF-3382.1 Nomenclature.

The symbols used in this paragraph are defined as follows:

TL_y	= support test load at or below yield
TL_u	= support test load at which a substantial increase in load displacement results in zero or negative increase in actual support load
F_{all}	= allowable value for the type of stress in NF-3310, ksi
$S_{u(act)}$	= actual tensile strength of the material used in the part or support which had reached ultimate capacity during the test
$S_{y(act)}$	= actual yield strength of the material used in the part or support which yielded during the test
KI	= load rating coefficient for supports in compression

NF-3382.2 Linear-Type Supports.

The load ratings for Linear-Type Supports for the Service Loadings shall be determined by the following equations:

Design and Level A Limits (lower of the two values)

$$\text{load rating}_{(\text{yield})} = TL_y \times 1.0 \frac{F_{\text{all}}}{S_{y(\text{act})}} \quad (1)$$

$$\text{load rating}_{(\text{ult.})} = TL_u \times 1.0 \frac{F_{\text{all}}}{S_{u(\text{act})}}$$

(1)

Test and Level B Limits (lower of the two values)

$$\text{load rating}_{(\text{yield})} = TL_y \times 1.33 \frac{F_{\text{all}}}{S_{y(\text{act})}} \quad (2)$$

$$\text{load rating}_{(\text{ult.})} = TL_u \times 1.33 \frac{F_{\text{all}}}{S_{u(\text{act})}}$$

(2)

Level C Limits (lower of the two values)

$$\text{load rating}_{(\text{yield})} = TL_y \times 1.5 \frac{F_{\text{all}}}{S_{y(\text{act})}} \quad (3)$$

$$\text{load rating}_{(\text{ult.})} = TL_u \times 1.5 \frac{F_{\text{all}}}{S_{u(\text{act})}}$$

(3)

NF-3382.3 Supports Loaded in Compression.

The load rating for the supports loaded in compression shall be determined for Service Level A, B, and C by the methods of NF-3382.2. In addition, for cases where buckling governs, TL_u shall be corrected for the ratio of Young's Modulus at the Design Temperature to Young's Modulus at the test temperature. The load rating shall be determined by the following equations:

Design and Level A Limits

$$\text{load rating} = 0.52 Kl \times TL_u$$

Test and Level B Limits

$$\text{load rating} = 0.67 Kl \times TL_u$$

Level C limits

$$\text{Load rating} = 0.67 Kl \times TL_u$$

Kl

= 1.0 for elastic buckling

$$Kl = \frac{S_y}{S_{y(\text{act})}} \text{ for inelastic buckling}$$

TERM

NF-3382.4 Alternate Load Rating Method Using TL_y or TL_u Test Results Only.

Either TL_y or TL_u test results may be used to establish a support load rating provided the load rating as determined by the method of NF-3382.2 or NF-3382.3 is modified as follows:

(a) For load rating based on TL test results only:

(1) for supports constructed of materials having definitely determinable yield points and specified minimum S_y/S_u ratios not greater than 0.625, the load rating shall be multiplied by 0.83. If $S_{y(akt)}$ of the material is not known, 150% of the material specified minimum yield strength shall be assumed as the $S_y/S_{y(akt)}$ in place of multiplier 0.83;

(2) for supports constructed of carbon steel with specified minimum tensile strengths of not over 70,000 psi (480 MPa), $S_{y(akt)}$ shall be increased by 5000 psi (34 MPa) prior to determining the load rating;

(3) for all other materials the determined load rating shall be multiplied by 0.67.

For supports loaded in compression, a TL_u test shall be performed with the compressive load rating determined in accordance with NF-3382.3.

(b) For load rating based on TL_u test results, the determined load rating shall be multiplied by 0.50.

Page 94

NF-3400 DESIGN RULES FOR STANDARD SUPPORTS

NF-3410 GENERAL REQUIREMENTS

The following requirements apply in addition to the requirements of NF-3100, NF-3200, and NF-3300.

NF-3411 General Design Requirements

Standard Supports (NF-1214) shall conform to the design considerations of NF-3120, the design rules of NF-3200 or NF-3300, and the following additional requirements.

NF-3411.1 Standard Supports Used as Component Supports.

Standard Supports may be used as component supports, as defined in NF-3500.

NF-3411.2 Standard Supports Used as Piping Supports.

Standard Supports may be used as piping supports, as defined in NF-3600.

NF-3411.3 Loads

(a) Standard Supports shall be capable of carrying all concurrently acting loads listed in NF-3111 and stipulated in the Design Specification. The supports shall be designed to provide the required supporting effort and to permit the designed piping or component movement.

(b) Spring supports shall be capable of exerting a supporting force equal to the load, as determined by weight-balance calculations, plus the weight of all hanger parts such as clamps and rods that will be supported by a spring at the point of attachment to a pressure retaining component or to an integral attachment.

(1) The design shall be such as to prevent complete release of the piping or component load in the event of spring failure or misalignment.

(2) When springs are to be enclosed in spaces where high ambient temperatures occur, the spring material shall be such that the spring constants will not be significantly changed at the temperature to be experienced.

(c) Snubbers shall meet the requirements of (a) above and (1) and (2) below.

(1) The following occasional loads shall be considered:

(a) seismic inertial;

(b) seismic anchor displacement;

(c) hydraulic transient loads resulting from, but not limited to, water hammer, steam hammer, pump startup, pump shutdown, safety and safety relief valve discharges, as specified in the Design Specification.

(2) *Thermal Expansion and Thermal Anchor Displacement.* The snubber shall not resist the effects of thermal growth of the component, the piping system, or the anchorage to the degree where it imposes a significant load or stress on the piping or component.

NF-3412 Standard Support Items

NF-3412.1 Constant Support Spring Hangers.

Constant support spring hangers may be used to support piping or components at those locations requiring a substantially uniform supporting force throughout the travel range but which, while subject to thermal movement, cannot tolerate appreciable variability of the supporting force. They shall have a mean variability (deviation), including friction, of no more than 6% throughout the travel range. Deviation is the sum of kinematic friction and manufacturing tolerance factors. Determination of deviation is by load test machine and is calculated as follows:

deviation = (maximum reading moving down

- minimum reading moving up)

÷ (maximum reading moving down

+ minimum reading moving up)

NF-3412.2 Variable Support Spring Hangers.

Variable support spring hangers may be used to support piping or components at those locations subject to vertical movement due to temperature differences, where a variability of the supporting force up to a factor of 0.25, as calculated by the following equation, can be tolerated:

$$\text{variability factor} = (\text{travel} \times \text{spring rate}) / \text{load}$$

(a) The variability of the supporting force resulting from movement of the piping or component shall be considered in the loadings used in the stress analysis of the piping or component.

(b) Variable support spring hangers shall be provided with means to limit misalignment, buckling, and eccentric loading and to prevent overstressing of the spring.

(c) It is recommended that all hangers employing springs be provided with means to indicate at all times the compression of the spring with respect to the appropriate hot and cold positions of the piping or component.

NF-3412.3 Hanger Rods.

Design loads for threaded hanger rods shall be based on the root area of the threads. In no case shall hanger rods less than $\frac{3}{8}$ in. (10 mm) diameter be used for supporting pipe 2 in.

Page 95

(DN 50) and smaller, or less than $\frac{1}{2}$ in. (13 mm) diameter rod for supporting pipe $2\frac{1}{2}$ in. (DN 65) and larger. Pipe, structural shapes, or bars may be used instead of hanger rods. Hanger rods, structural shapes, etc., shall be designed to permit the free movement of piping as indicated in the thermal stress analysis. The possibility of moment loading of hanger rods or shapes as a result of pipe motion shall be considered and avoided unless the support is specifically designed for such loading.

NF-3412.4 Snubbers

(a) Snubbers may be incorporated in the system design to accommodate Design Mechanical Loads or conditions of a vibratory or dynamic nature. Snubbers may be attached to a piping or component to protect it against dynamic type loading. Snubbers shall allow essentially free movement of the piping or component to which they are attached during nondynamic application of load such as that imposed by expansion and contraction.

(b) Snubbers shall be carefully applied to ensure that they will perform their intended function without placing unacceptable loads on the piping system or other components.

(c) The Design Specification shall contain, as a minimum, the following:

(1) the Design Loadings for loading conditions and transients, and combinations of loadings for which the snubber is designed to accommodate;

(2) required force, time, and displacement relationship;

(3) the environmental conditions that the snubber will be exposed to, such as:

(a) temperature

(b) irradiation

(c) corrosive atmosphere

(d) moisture

(e) airborne particles

(4) consideration of material characteristics, such as:

(a) compatibility

(b) stability

(c) fire resistance

(d) wear

(e) aging

(5) tests which are required prior to installation.

(d) Design of functional members such as interconnections, tubing and fittings reservoirs, and flow distributors shall consider the effect of internal pressure, thermal expansion, and vibration loading.

NF-3420 DESIGN BY ANALYSIS FOR CLASS 1

NF-3421 General Design Requirements

The design of Class 1 Standard Supports shall be in accordance with the requirements of NF-3420 using one of the design procedures indicated in Table NF-3131(a)-1 for Class 1 construction.

NF-3422 Design of Plate- and Shell-Type Standard Supports

The requirements of NF-3200 shall be met.

NF-3423 Design of Linear-Type Standard Supports

The requirements of NF-3300 shall be met.

NF-3425 Design of Bolting

The requirements of NF-3225 and NF-3324.6 shall be met.

NF-3426 Design of Welded Joints

NF-3426.1 Permissible Types.

The permissible types of welded joints for Standard Supports are described in paragraphs NF-3226.1 and NF-3256.1. Additional types of joints are as follows. Typical examples of the types are shown in Fig. NF-3426.1-1.

(a) *Tee Joints*. Tee joints shall be one of the following:

(1) fillet, double welded, sketch (a-1);

(2) fillet, single welded, when double members are used, sketch (a-2);

(3) fillet, single welded, between a flat surface and the end surface of a closed tubular section or a closed formed section, sketch (f). Partially closed tubular sections or partially closed formed sections and the total length of their respective welds shall encompass a minimum of 270 deg. of the circumference and provide symmetrical loadings on closure plates.

(b) *Corner Joints.* Corner joints shall be one of the following.

(1) Partial penetration, without a fillet weld between the edge of a plate and the end surface of a closed tubular section or partially closed formed section, sketch (e). Partially closed tubular sections or partially closed formed sections as well as the total length of their respective welds shall encompass a minimum of 270 deg. of the circumference and provide symmetrical loadings on closure plates;

Page 96

FIG. NF-3426.1-1 ADDITIONAL PERMISSIBLE WELDED JOINTS FOR CLASS 1 STANDARD SUPPORTS

FIG. NF-3426.1-1 ADDITIONAL PERMISSIBLE WELDED JOINTS FOR CLASS 1 STANDARD SUPPORTS

(2) Fillet welds between the edge of a plate and the end surface of a closed tubular section or partially closed tubular section or partially closed formed section, sketches (b), (c), and (d). In addition, weld joints (b) and (d) may be used only if the lengths of the respective legs of the fillet weld are equal to the exposed thickness of the plate and shell elements. Partially closed tubular sections or partially closed formed sections as well as the total length of their

respective welds shall encompass a minimum of 270 deg. of the circumference and provide symmetrical loadings on closure plates.

(3) The use of welded joints permitted by (a)(3) and (b) above is limited to housings for spring encapsulation of standard supports.

NF-3426.2 Design Stress Intensity and Allowable Stress Limits for Welded Joints.

The limit of design stress intensity or of allowable stress for welded joints for Standard Supports shall not exceed the applicable design stress intensity value or allowable stress value for the base metal being joined.

NF-3450 DESIGN BY ANALYSIS FOR CLASS 2 AND MC

NF-3451 General Design Requirements

The design of Class 2 and MC Standard Supports shall be in accordance with the requirements of NF-3450

Page 97

using one of the design procedures indicated in Table NF-3131(a)-1.

NF-3452 Design of Plate- and Shell-Type Standard Supports

The requirements of NF-3200 shall be met.

NF-3453 Design of Linear-Type Standard Supports

The requirements of NF-3300 shall be met.

NF-3455 Design of Bolting

The requirements of NF-3225 and NF-3324.6 shall be met.

NF-3456 Design of Welded Joints

The requirements of NF-3426 shall be met, except that for groove welded and fillet welded T-joints, the welds may be intermittent instead of continuous.

NF-3460 DESIGN BY ANALYSIS FOR CLASS 3

The design of Class 3 Standard Supports shall be in accordance with the requirements of NF-3450, using one of the design procedures indicated in Table NF-3131(a)-1.

NF-3470 DESIGN BY EXPERIMENTAL STRESS ANALYSIS

Standard Supports may be designed by experimental stress analysis in accordance with the requirements of NF-3270 for Plate- and Shell-Type Standard Supports and NF-3370 for Linear-Type Standard Supports.

NF-3480 PROCEDURE FOR LOAD RATING

Standard Supports may be designed by the procedure for load rating in accordance with the requirements of NF-3280 for Plate- and Shell-Type Standard Supports and NF-3380 for Linear-Type Standard Supports.

NF-3500 DESIGN RULES FOR COMPONENT SUPPORTS

NF-3510 GENERAL REQUIREMENTS

The design of component supports shall be in accordance with this Subarticle and the applicable general requirements of NF-3110, NF-3210, NF-3310, and NF-3410.

NF-3520 DESIGN BY ANALYSIS FOR CLASS 1

NF-3521 General Design Requirements

This Subsubarticle provides stress limits for elements of Class 1 component supports. For general requirements as to stress determinations, definitions, derivations of stress intensities, and classification of stresses, refer to NF-3120.

NF-3522 Design of Plate- and Shell-Type Component Supports

(a) The design rules and stress intensity limits which must be satisfied for the Design and Service Loadings are given in NF-3220.

(b) When design by analysis is used, the stress limit factors for each loading and stress category are specified in Table NF-3522(b)-1.

NF-3523 Design of Linear-Type Component Supports

(a) The design rules and stress limits which must be satisfied for the Design and Service Loadings are given in NF-3320.

(b) When design by analysis is used, the stress limit factors for each loading and stress category are specified in Table NF-3523(b)-1.

NF-3524 Design of Standard Component Supports

(a) The design rules and stress limits which must be satisfied for the Design and Service Loadings are given in NF-3420.

(b) When design by analysis is used, the stress limit factors for each loading and stress category are specified

Page 98

in Table NF-3522(b)-1 or Table NF-3523(b)-1, as applicable.

TABLE NF-3522(b)-1
ELASTIC ANALYSIS STRESS CATEGORIES AND STRESS LIMIT FACTORS FOR CLASS 1 PLATE- AND SHELL-
TYPE SUPPORTS DESIGNED BY ANALYSIS — COMPONENT SUPPORTS

Stress Limit Factors for Loading Categories [Note (1)]						
Stress Category	Design	Service Level A	Service Level B [Note (2)]	Service Level C [Note (3)]	Service Level D	Test Loadings
Primary stresses [Notes (4), (5)]	$K_m = 1.0$	$K_m = 1.0$	$K_m = 1.33$	$K_m = 1.5$		$K_m = 1.33$
	$K_v = 1.0$	$K_v = 1.0$	$K_v = 1.33$	$K_v = 1.5$		$K_v = 1.33$
	$K_{bk} = 1.0$	$K_{bk} = 1.0$	$K_{bk} = 1.33$	$K_{bk} = 1.5$	Use Appendix F	$K_{bk} = 1.33$
	but stress $\leq \frac{1}{2}$ of critical buckling stress	but stress $\leq \frac{1}{2}$ of critical buckling stress	but stress $\leq \frac{1}{2}$ of critical buckling stress	but stress $\leq \frac{1}{2}$ of critical buckling stress		but stress $\leq \frac{1}{2}$ of critical buckling stress
Primary plus secondary stresses [Note (5)]	Evaluation is required for critical buckling for all loading categories. The requirements of this Subarticle shall be met for this evaluation.					
Peak stresses	Evaluation not required.					

GENERAL NOTES:

K_m = stress limit factor applicable to the Design allowable membrane stress intensity or membrane plus bending stress intensity (see NF-3221.1 and NF-3221.2).

K_v = stress limit factor applicable to the Design allowable shear stress (see NF-3223.2)

K_{bk} = stress limit factor applicable to the Design allowable membrane stress intensity or membrane plus bending stress intensity (compression only)

NOTES:

(1) Control of deformation is not assured by these stress limit factors. When required by Design Specification, deformation control must be considered separately.

(2) K_m , K_v , and $K_{bk} = 1.0$ for design of snubbers.

(3) Stress shall not exceed $0.7 S_u$.

(4) For Service Levels A, B, C, and D, stresses induced on the supports by restraint of free-end displacement and anchor motions of piping shall be considered as primary stresses.

(5) Thermal stresses within the support as defined by NF-3121.11 need not be evaluated. For Service Levels A and B, primary plus secondary stresses shall be limited to a range of $2 S_y$ or S_u at temperature, whichever is less.

TABLE NF-3522(b)-1 ELASTIC ANALYSIS STRESS CATEGORIES AND STRESS LIMIT FACTORS FOR CLASS 1 PLATE- AND SHELL-TYPE SUPPORTS DESIGNED BY ANALYSIS - COMPONENT SUPPORTS

NF-3525 Design of Bolting

The number and cross-sectional area of bolts required for the Design Loadings of NF-3112 shall be determined in accordance with the procedures of NF-3324.6.

NF-3526 Design of Welded Joints

- (a) Welded joints in Plate- and Shell-Type Component Supports shall be as stipulated in NF-3226.
 (b) Welded joints used in Linear-Type Component Supports shall be as stipulated in NF-3324.5.

NF-3550 DESIGN BY ANALYSIS FOR CLASS 2, 3, AND MC

NF-3552 Design of Plate- and Shell-Type Component Supports

- (a) The design rules and stress limits which must be satisfied for the Design and Service Loadings are given in NF-3250 and NF-3260.
 (b) When design by analysis is used, the stress limit factors for each loading and stress category are specified in Table NF-3552(b)-1.

NF-3553 Design of Linear-Type Component Supports

The design rules and stress limits which must be satisfied for the Design and Service Loadings are given in NF-3523.

Page 99

	$K_v = 1.0$	$K_v = 1.0$	$K_v = 1.33$ [Note (5)]	$K_v = 1.5$ [Note (5)]	Use Appendix F	$K_v = 1.33$ [Note (5)]
	$K_{bk} = 1.0$	$K_{bk} = 1.0$	$K_{bk} = 1.33$ but stress $\leq \frac{2}{3}$ of critical buckling stress	$K_{bk} = 1.5$ but stress $\leq \frac{2}{3}$ of critical buckling stress		$K_{bk} = 1.33$ but stress $\leq \frac{2}{3}$ of critical buckling stress
Primary plus secondary stresses [Note (6)]	Evaluation is required for critical buckling for all loading categories. The requirements of this Subarticle shall be met for this evaluation.					
Peak stresses	Evaluation not required.					

GENERAL NOTES:

K_s = stress limit factor applicable to the Design allowable tensile and bending stresses (see NF-3321.1, NF-3322.1, NF-3350, and NF-3360)
 K_v = stress limit factor applicable to the Design allowable shear stresses (see NF-3321.1, NF-3322.1, NF-3350, and NF-3360)
 K_{bk} = stress limit factor applicable to the Design allowable compressive axial and bending stresses to determine buckling limit

NOTES:

- (1) Control of deformation is not assured by these stress limit factors. When required by Design Specification, deformation control must be considered separately.
- (2) K_s , K_v , and $K_{bk} = 1.0$ for design of snubbers.
- (3) Stress shall not exceed $0.7 S_u$.
- (4) For Service Levels A, B, C, and D, stresses induced on the supports by restraint of free-end displacement and anchor motions of piping shall be considered as primary stresses.
- (5) Shear stress shall not exceed $0.42 S_u$.
- (6) Thermal stresses within the support as defined by NF-3121.11 need not be evaluated. For Service Levels A and B, primary plus secondary stresses shall be limited to a range of $2 S_y$ or S_u at temperature, whichever is less.

TABLE NF-3523(b)-1 ELASTIC ANALYSIS STRESS CATEGORIES AND STRESS LIMIT FACTORS FOR CLASS 1, 2, 3, AND MC LINEAR-TYPE SUPPORTS DESIGNED BY ANALYSIS - COMPONENT SUPPORTS

NF-3554 Design of Standard Component Supports

The design of Standard Component Supports shall be in accordance with NF-3524.

NF-3555 Design of Bolting

The provision of NF-3525 shall be met.

NF-3556 Design of Welded Joints

(a) Welded joints in Plate- and Shell-Type Component Supports shall be as stipulated in NF-3256 for Class 2 and MC and NF-3266 for Class 3.

(b) Welded joints in Linear-Type Component Supports shall be as stipulated in NF-3324.5.

NF-3570 EXPERIMENTAL STRESS ANALYSIS

Component supports of all types may be designed by experimental stress analysis in accordance with Appendix II of Section III, Division 1, Appendices.

NF-3580 DESIGN BY LOAD RATING

Component supports of all types may be designed by load rating in accordance with the requirements of NF-3280 for Plate- and Shell-Type, NF-3380 for Linear-Type, and the applicable Subsubarticle for Standard Component Supports.

TABLE NF-3552(b)-1 ELASTIC ANALYSIS STRESS CATEGORIES AND STRESS LIMIT FACTORS FOR CLASS 2, 3, AND MC PLATE- AND SHELL-TYPE SUPPORTS DESIGNED BY ANALYSIS - COMPONENT SUPPORTS

NF-3600 DESIGN RULES FOR PIPING SUPPORTS

NF-3610 GENERAL REQUIREMENTS

The design of piping supports shall be in accordance with this Subarticle and the applicable general requirements of NF-3110, NF-3210, NF-3310, and NF-3410.

NF-3611 Spacing of Piping Supports

Supports for piping with a longitudinal axis in approximately a horizontal position shall be spaced to prevent excessive shear stresses resulting from sag and bending in the piping, with special consideration given when components such as pumps and valves impose concentrated loads. The suggested maximum spans for spacing of weight supports for standard weight and heavier piping are given in Table NF-3611-1.

NF-3612 Vibration

Piping shall be arranged and supported so that vibration will be minimized.

NF-3613 Anchors, Guides, Pivots, and Restraints

Anchors, guides, pivots, and restraints shall be designed to secure the desired points of piping in a relatively fixed position. They shall permit the piping to expand and contract freely as directed from the anchored or guided point and shall be structurally capable of withstanding the thrusts, moments, and other imposed loads.

NF-3614 Support Adjustments

(a) Screwed adjustments shall have threaded parts to conform to ANSI B1.1 coarse threaded series, Class 2 fit. Alternatively, other thread forms, series, and fits may be used which permit adjustment after erection, and are designed to withstand the forces, moments, and other imposed loads acting on the support, considering the worst combination of thread tolerances.

(b) Turnbuckles and adjusting nuts shall have the full length of thread in engagement. Means shall be provided for determining that full thread length is

Page 101

engaged. All screw and equivalent adjustments shall be provided with suitable locking devices.

**TABLE NF-3611-1
SUGGESTED PIPING SUPPORT SPACING**

Nominal Pipe Size, in.	Suggested Maximum Span, ft	
	Water Service	Steam, Gas, or Air Service
1	7	9
2	10	13
3	12	15
4	14	17
6	17	21
8	19	24
12	23	30
16	27	35
20	30	39
24	32	42

GENERAL NOTES:

- (a) Suggested maximum spacing between piping supports for horizontal straight runs of standard and heavier piping with a maximum operating temperature of 750°F.
- (b) Does not apply where span calculations are made or where there are concentrated loads between supports such as flanges, valves, specialties, etc.
- (c) The spacing is based on a maximum combined bending and shear stress of 1.5 ksi and insulated piping filled with water or the equivalent weight of steel pipe for steam, gas, or air service, and the pitch of the line is such that a sag of 0.1 in. between supports is permissible.

TABLE NF-3611-1 SUGGESTED PIPING SUPPORT SPACING

NF-3615 Piping Clamps

(a) When clamps are used to support vertical piping lines, it is recommended that shear lugs be welded to the piping to prevent slippage.

(b) In addition to the provision of (a) above, clamps to support vertical piping lines shall be designed to support the total load on either arm in the event the load shifts because of piping or hanger movement, or both.

NF-3616 Hanger Rods

The provisions for hanger rods of NF-3412.3 apply.

NF-3620 DESIGN BY ANALYSIS FOR CLASS 1

NF-3622 Design of Plate- and Shell-Type Piping Supports

(a) The design rules and stress intensity limits which must be satisfied for the Design and Service Loadings are given in NF-3220.

(b) When design by analysis is used, the stress intensity limit factors for each loading and stress category are specified in Table NF-3622(b)-1.

NF-3623 Design of Linear-Type Piping Supports

(a) The design rules and stress limits which must be satisfied for the Design and Service Loadings are given in NF-3320.

(b) When design by analysis is used, the stress limit factors for each loading and stress category are specified in Table NF-3623(b)-1.

NF-3624 Design of Standard Piping Supports

(a) The design rules and stress limits which must be satisfied for the Design and Service Loadings are given in NF-3420.

(b) When design by analysis is used, the stress limit factors for each loading and stress category are specified in Table NF-3622(b)-1 or Table NF-3623(b)-1, as applicable.

NF-3625 Design of Bolting

The number and cross-sectional area of bolts required for the Design Loadings of NF-3112 shall be determined in accordance with the procedures of NF-3324.6. The allowable bolt design stress value shall be determined in accordance with NF-3324.6.

NF-3626 Design of Welded Joints

(a) Welded joints in Plate- and Shell-Type Piping Supports shall be as stipulated in NF-3226. In addition, tee joints, double fillet welded, sketch (a) [Fig. NF-3626(a)-1] and single welded, when double members, sketch (b), are permitted.

(b) Welded joints used in Linear-Type Piping Supports shall be as stipulated in NF-3324.5.

	but stress $\leq \frac{1}{2}$ of critical buckling stress	but stress $\leq \frac{1}{2}$ of critical buckling stress	but stress $\leq \frac{1}{2}$ of critical buckling stress	but stress $\leq \frac{1}{2}$ of critical buckling stress		but stress $\leq \frac{1}{2}$ of critical buckling stress
Primary plus secondary stresses [Note (5)]	Evaluation is required for critical buckling for all loading categories. The requirements of this Subarticle shall be met for this evaluation.					
Peak stresses	Evaluation not required.					

GENERAL NOTES:

K_m = stress limit factor applicable to the Design allowable membrane stress intensity or membrane plus bending stress intensity (see NF-3221.1 and NF-3221.2)

K_v = stress limit factor applicable to the Design allowable shear stress (see NF-3223.2)

K_{bk} = stress limit factor applicable to the Design allowable membrane stress intensity or membrane plus bending stress intensity (compression only)

NOTES:

(1) Control of deformation is not insured by these stress limit factors. When required by Design Specification, deformation control must be considered separately.

(2) K_m , K_v , and $K_{bk} = 1.0$ for design of snubbers.

(3) Stress shall not exceed $0.7 S_u$.

(4) For Service Levels A, B, C, and D, stresses induced on the supports by restraint of free-end displacement and anchor motions of piping shall be considered as primary stresses.

(5) Thermal stresses within the support as defined by NF-3121.11 need not be evaluated.

TABLE NF-3622(b)-1 ELASTIC ANALYSIS STRESS CATEGORIES AND STRESS LIMIT FACTORS FOR CLASS 1 PLATE- AND SHELL-TYPE SUPPORTS DESIGNED BY ANALYSIS - PIPING SUPPORTS

NF-3650 DESIGN BY ANALYSIS FOR CLASS 2, 3, AND MC

NF-3652 Design of Plate- and Shell-Type Piping Supports

(a) The design rules and stress limits which must be satisfied for the Design and Service Loadings are given in NF-3250 and NF-3260.

(b) When design by analysis is used, the stress limit factors for each loading and stress category are specified in Table NF-3652(b)-1.

NF-3653 Design of Linear-Type Piping Supports

The design rules and stress limits which must be satisfied for the Design and Service Loadings are given in NF-3623.

NF-3654 Design of Standard Piping Supports

The design of Standard Piping Supports shall be in accordance with NF-3624.

NF-3655

The provisions of NF-3625 shall be met.

NF-3656 Design of Welded Joints

(a) Welded joints in Plate- and Shell-Type Piping Supports shall be as stipulated in NF-3256 for Class 2 and MC and NF-3266 for Class 3.

(b) Welded joints used in Linear-Type Piping Supports shall be as stipulated in NF-3324.5.

Stress Limit Factors for Loading Categories [Note (1)]						
Stress Category	Design	Service Level A	Service Level B [Note (2)]	Service Level C [Note (3)]	Service Level D	Test Loadings
Primary stresses [Notes (4), (6)]	$K_s = 1.0$	$K_s = 1.0$	$K_s = 1.33$	$K_s = 1.5$		$K_s = 1.33$
	$K_v = 1.0$	$K_v = 1.0$	$K_v = 1.33$ [Note (5)]	$K_v = 1.5$ [Note (5)]	Use Appendix F	$K_v = 1.33$ [Note (5)]
	$K_{bk} = 1.0$	$K_{bk} = 1.0$	$K_{bk} = 1.33$ but stress $\leq \frac{2}{3}$ of critical buckling stress	$K_{bk} = 1.5$ but stress $\leq \frac{2}{3}$ of critical buckling stress		$K_{bk} = 1.33$ but stress $\leq \frac{2}{3}$ of critical buckling stress
Primary plus secondary stresses [Note (6)]	Evaluation is required for critical buckling for all loading categories. The requirements of this Subarticle shall be met for this evaluation.					
Peak stresses	Evaluation not required.					

GENERAL NOTES:

K_s = stress limit factor applicable to the Design allowable tensile and bending stresses (see NF-3623 and NF-3653)

K_v = stress limit factor applicable to the Design allowable shear stresses (see NF-3623 and NF-3653)

K_{bk} = stress limit factor applicable to the Design allowable compressive axial and bending stresses to determine buckling limit

NOTES:

(1) Control of deformation is not assured by these stress limit factors. When required by Design Specification, deformation control must be considered separately.

(2) K_s , K_v , and $K_{bk} = 1.0$ for design of snubbers.

(3) Stress shall not exceed $0.7 S_y$.

(4) For Service Levels A, B, C, and D, stresses induced on the supports by restraint of free-end displacement and anchor motions of piping shall be considered as primary stresses.

(5) Shear stress shall not exceed $0.42 S_y$.

(6) Thermal stresses within the support as defined by NF-3121.11 need not be evaluated.

GENERAL NOTES:

K_m = stress limit factor applicable to the Design allowable membrane stress or membrane plus bending stresses (see NF-3251.1 and NF-3261)

K_v = stress limit factor applicable to the Design allowable shear stress (see NF-3252.2 and NF-3261)

K_{bk} = stress limit factor applicable to the Design allowable membrane stress or membrane plus bending stress (compression only)

NOTES:

(1) Control of deformation is not assured by these stress limit factors. When required by Design Specification, deformation control must be considered separately.

(2) K_m and K_{bk} = 1.0 for design of snubbers.

(3) For Service Limits A, B, C, and D, stresses induced on the supports by restraint of free-end displacement and anchor motions of piping shall be considered as primary stresses.

(4) Shear stress shall not exceed $0.42 S_u$.

(5) Thermal stresses within the support as defined by NF-3121.11 need not be evaluated.

(6) Stress shall not exceed $0.7 S_u$.

TABLE NF-3652(b)-1 ELASTIC ANALYSIS STRESS CATEGORIES AND STRESS LIMIT FACTORS FOR CLASS 2, 3, AND MC PLATE- AND SHELL-TYPE SUPPORTS DESIGNED BY ANALYSIS - PIPING SUPPORTS

NF-3670 EXPERIMENTAL STRESS ANALYSIS

Piping supports of all types may be designed by experimental stress analysis in accordance with Appendix II of Section III, Division 1, Appendices.

NF-3680 DESIGN BY LOAD RATING

Piping supports of all types may be designed by load rating in accordance with the requirements of NF-3280 for Plate- and Shell-Type, NF-3380 for Linear-Type, and the applicable Subsubarticle for Standard Piping Supports.

July 1, 1998

American Society Of Mechanical Engineers

SEC III D1 NF-4000

ARTICLE NF-4000 FABRICATION AND INSTALLATION

Page 105

NF-4100 GENERAL REQUIREMENTS

NF-4110 INTRODUCTION

NF-4111 Fabrication and Installation

Supports shall be fabricated and installed in accordance with the requirements of this Article and shall be manufactured from material which meets the requirements of NF-2000.

NF-4112 Reassembly of Subsection NF Supports

The Certificate Holder may reassemble supports from completed supports that have not been in operating service or from parts and material of disassembled supports that have not been in operating service, provided all required documentation is available and the applicable Code requirements are met.

The program for maintaining identification of material and parts, including disposition of nameplate and stamping and material documentation or Data Reports, as applicable, shall be described in a written procedure that shall be submitted to the cognizant Authorized Nuclear Inspector for review and acceptance.

NF-4120 CERTIFICATION OF MATERIALS AND FABRICATION BY SUPPORT CERTIFICATE HOLDER

NF-4121 Means of Certification

The Certificate Holder for an item shall certify, by application of the appropriate Code symbol and completion of the appropriate Data Report in accordance with NCA-8000, that the materials used comply with all the requirements of NF-2000 and that the fabrication or installation complies with the requirements of NF-4000.

NF-4121.1 Certification of Treatments, Tests, and Examinations.

If the Certificate Holder performs treatments, tests, repairs, or examinations required by other Articles of this Section, he shall certify that he has fulfilled that requirement [NCA-3861(c)]. Reports of all required treatments and the results of all required tests, repairs, and examinations performed shall be available to the Inspector.

NF-4121.2 Repetition of Tensile or Impact Tests.

If during the fabrication or installation of the support the material is subjected to heat treatment that has not been covered by treatment of the test coupons (NF-2200) and that may reduce either the tensile or impact properties below the required values, the tensile and impact tests shall be repeated by the Certificate Holder on test specimens taken from test coupons which have been taken and treated in accordance with the requirements of NF-2000.

NF-4122 Material Identification

Material for supports shall carry identification markings which will remain distinguishable until the support is fabricated or installed. If the original identification markings are cut off or the material is divided, the marks shall be accurately transferred to the parts or a coded marking shall be used to assure identification of each piece of material during subsequent fabrication or installation, unless otherwise provided by NF-2150. Material supplied with a Certificate of Compliance and welding and brazing material shall be identified and controlled so that they can be traced to each support, or else a control procedure shall be employed which ensures that the specified material is used.

NF-4123 Examinations

Visual examination activities that are not referenced for examination by other specific Code paragraphs, and are performed solely to verify compliance with

Page 110

requirements of NF-4000, may be performed by the persons who perform or supervise the work. These visual examinations are not required to be performed by personnel and procedures qualified to NF-5500 and NF-5100, respectively, unless so specified.

NF-4125 Testing of Welding and Brazing Materials

All welding and brazing materials shall meet the requirements of NF-2400.

NF-4130 REPAIR OF MATERIAL

NF-4131 Elimination and Repair of Defects

Material originally accepted on delivery in which defects exceeding the limits of NF-2500 are known or discovered during the process of fabrication or installation is unacceptable. The material may be used provided the condition is corrected in accordance with the requirements of NF-2500 for the applicable product form, except:

(a) weld repair is not required if the defect is removed by mechanical means and does not reduce the section below the minimum thickness required by NF-3000;

(b) when weld repair is performed,

(1) the weld repair restores the section to the minimum thickness required by NF-3000;

(2) the limitation on the depth of weld repair does not apply;

(3) the time of examination of weld repairs to weld edge preparations and to material shall be in accordance with NF-5120; and

(4) the provisions of NF-2610(e) for weld repair of structural material apply.

NF-4200 FORMING, FITTING, AND ALIGNING

NF-4210 CUTTING, FORMING, AND BENDING

NF-4211 Cutting

Material may be cut to shape and size by mechanical means such as machining, shearing, or chipping, or by grinding or thermal cutting. Thermally cut edges that are to be welded shall be smooth and free of all loose scale and slag accumulations.

NF-4211.1 Preheating Before Thermal Cutting.

When thermal cutting is performed to prepare weld joints or edges, to remove attachments or defective material, or for any other purpose, consideration shall be given to preheating the material using preheat schedules, such as suggested in Appendix D (Section III, Division 1, Appendices).

NF-4212 Forming and Bending Processes

Any process may be used to hot or cold form or bend materials, including weld metal, provided the required dimensions are attained (see NF-4214 and NF-4220), and provided the specified impact properties of the material, when required, are not reduced below the minimum specified values or they are effectively restored by heat treatment following the forming operation. *Hot forming* is defined as forming with the material temperature higher than 100°F (56°C) below the lower transformation temperature of the material. When required, the process shall be qualified for impact properties as outlined in NF-4213.

NF-4213 Qualification of Forming Processes for Impact Property Requirements

When impact testing is required by the Design Specifications, a procedure qualification test shall be conducted using specimens taken from material of the same material specification, grade or class, heat treatment, and with similar impact properties as required for the material in the support. These specimens shall be subjected to the equivalent forming or bending process and heat treatment as the material in the support. Applicable tests shall be conducted to determine that the required impact properties of NF-2300 are met after straining.

NF-4213.1 Exemptions.

Procedure qualification tests are not required for material listed in (a) through (f) below:

(a) hot formed material, such as forgings, in which the hot forming is completed by the Material Organization prior to removal of the impact test specimens;

(b) hot formed material represented by test coupons which has been subjected to heat treatment representing the hot forming procedure and the heat treatments to be applied to the parts;

(c) material which does not require impact tests in accordance with NF-2300;

(d) material which has final strain less than 0.5%;

(e) material where the final strain is less than that of a previously qualified procedure for that material;

(f) material from which the impact testing required by NF-2300 is performed on each heat and lot, as applicable, after forming.

Page 111

NF-4213.2 Procedure Qualification Test.

The procedure qualification test shall be performed in the manner stipulated in (a) through (f) below.

(a) The tests shall be performed on three different heats of material both before and after straining to establish the effects of the forming and subsequent heat treatment operations.

(b) Specimens shall be taken in accordance with the requirements of NF-2000 and shall be taken from the tension side of the strained material.

(c) The percent strain shall be established by the following formulas:

For cylinders:

$$\% \text{ strain} = 50t/R_f[1 - (R_f/R_o)]$$

For spherical or dished surfaces:

$$\% \text{ strain} = 75t/R_f[1 - (R_f/R_o)]$$

For pipe:

$$\% \text{ strain} = 100r/R$$

where

t = nominal thickness, in.

R_f = final radius to center line of shell, in.

R_o = original radius (equal to infinity for a flat part), in.

R = nominal bending radius to the center line of the pipe, in.

r = nominal radius of the pipe, in.

(d) The procedure qualification shall simulate the maximum percent surface strain, employing a bending process similar to that used in the fabrication of the material or by direct tension on the specimen.

(e) Sufficient Charpy V-notch specimens shall be taken from each of three heats of material to establish a transition curve showing in both the upper and lower shelves. On each of these three heats, tests consisting of three impact specimens shall be conducted at a minimum of five different temperatures distributed throughout the transition region. The upper and lower shelves may be established by the use of one test specimen each, depending on the product form.

(f) Using the results of the impact test data from each of three heats, taken both before and after straining, determine either:

(1) the maximum change in NDT temperature along with:

- (a) the maximum change of lateral expansion and energy of the temperature under consideration, or
- (b) the maximum change of temperature at the lateral expansion and energy levels under consideration; or
- (2) when lateral expansion is the acceptance criterion (NF-2300), either the maximum change in temperature or the maximum change in lateral expansion.

NF-4213.3 Acceptance Criteria for Formed Material.

To be acceptable, the formed material used in the support shall have impact properties before forming sufficient to compensate for the maximum loss of impact properties due to the qualified forming procedure used.

NF-4213.4 Requalification.

A new procedure qualification test is required when any of the following changes are made:

- (a) the actual postweld heat treatment time at temperature is greater than previously qualified considering NF-2211; if the material is not postweld heat treated, the procedure must be qualified without postweld heat treatment;
- (b) the maximum calculated strain of the material exceeds the previously qualified strain by more than 0.5%;
- (c) where preheat over 250°F is used in the forming or bending operation but not followed by a subsequent postweld heat treatment.

NF-4214 Minimum Thickness of Fabricated Material

If any fabrication operation reduces the thickness below the minimum required to satisfy the rules of NF-3000, the material may be repaired in accordance with NF-4130.

NF-4220 FORMING TOLERANCES

NF-4221 Tolerances for Plate- and Shell-Type Supports

(a) The outer surface of a Plate- and Shell-Type Support shall not deviate from the specified shape by more than the greater of $1\frac{1}{4}\%$ of the overall design dimension or those tolerances permitted by NF-4222 or NF-4223. Such deviations shall not include abrupt changes.

(b) For Plate- and Shell-Type Supports which are skirts, the difference between the maximum and minimum outside diameters shall not exceed 1% of the nominal outside diameter.

Page 112

NF-4222 Tolerances for Linear-Type Supports

Tolerances for Linear-Type Supports fabricated from built-up members may be as recommended in Nonmandatory Appendix K (Section III, Division 1, Appendices), unless otherwise specified in the Design Specifications.

NF-4223 Tolerances for Standard Supports

Tolerances for Standard Supports may be as recommended in Appendix K (Section III, Division 1, Appendices), unless otherwise specified in the Design Specifications.

NF-4230 FITTING AND ALIGNING

NF-4231 Fitting and Aligning Methods

Parts that are to be joined may be fitted, aligned, and retained in position during the joining operation by the use of bars, jacks, clamps, drift pins, tack welds, or temporary attachments. Mechanical devices shall be carefully used to avoid damage to surfaces of the parts and to avoid enlargement of bolt holes.

NF-4231.1 Tack Welds.

Tack welds used to secure alignment shall either be removed completely, when they have served their purpose, or their stopping and starting ends shall be properly prepared by grinding or other suitable means so that they may be satisfactorily incorporated into the final weld. Tack welds shall be made by qualified welders using qualified welding procedures. When tack welds are to become part of the finished weld, they shall be visually examined and defective tack welds removed.

NF-4231.2 Column Bases

(a) Column bases shall be set level and to correct elevation with full bearing on the masonry.

(b) Column bases shall be finished in accordance with the requirements of (b)(1) through (3) below.

(1) Rolled steel bearing plates 2 in. or less in thickness may be used without milling, provided a satisfactory contact bearing is obtained. Rolled steel bearing plates over 2 in. but not over 4 in. (102 mm) in thickness may be straightened by pressing or, if presses are not available, by milling for all bearing surfaces except those noted in (b)(3) below to obtain satisfactory contact bearing. Rolled steel bearing plates over 4 in. (102 mm) in thickness shall be milled for all bearing surfaces except as noted in (b)(3) below.

**TABLE NF-4232-1
MAXIMUM ALLOWABLE OFFSET IN
FINAL BUTT WELDED JOINTS**

Section Thickness, in.	Maximum Allowable Offset
Up to $\frac{3}{4}$, incl.	$\frac{1}{4}t$
Over $\frac{3}{4}$ to $1\frac{1}{2}$, incl.	$\frac{3}{16}$ in.
Over $1\frac{1}{2}$ to 2, incl.	$\frac{1}{8}t$
Over 2	Lesser of $\frac{1}{8}t$ or $\frac{3}{4}$ in.

TABLE NF-4232-1 MAXIMUM ALLOWABLE OFFSET IN FINAL BUTT WELDED JOINTS

(2) Column bases other than rolled steel bearing plates shall be planed for all bearing surfaces, except as noted in (b)(3) below.

(3) The bottom surfaces of bearing plates and column bases which are grouted to ensure full bearing contact on foundation need not be planed.

NF-4232 Maximum Offset of Aligned Sections

Alignment of butt joints shall be such that the maximum offset of the finished weld will not be greater than the applicable amount listed in Table NF-4232-1, where t is the nominal thickness of the thinner section of the joint.

NF-4232.1 Fairing of Offsets.

Any offset within the allowable tolerance of Table NF-4232-1 shall be blended uniformly over the width of the finished weld or, if necessary, by adding additional weld metal beyond what would otherwise be the edge of the weld.

NF-4240 REQUIREMENTS FOR WELDED JOINTS

Butt welds may be made with or without backing or consumable insert rings. When the use of permanent backing rings is undesirable [NF-3226.1(a) or NF-3256.1(a)]:

- (a) the backing ring shall be removed and the inside of the joint ground smooth; or
- (b) the joint shall be welded without backing rings; or
- (c) consumable insert rings shall be used.

NF-4300 WELDING QUALIFICATIONS

NF-4310 GENERAL REQUIREMENTS

NF-4311 Types of Processes Permitted

Only those welding processes which are capable of producing welds in accordance with the welding procedure

Page 113

qualification requirements of Section IX and this Subsection shall be used for welding support material or attachments thereto. Any process used shall be such that the records required by NF-4320 can be prepared except that records for stud welds shall be traceable to the welders and welding operators, and not necessarily to each specific weld.

NF-4311.1 Stud Welding Restrictions.

Stud welding is acceptable for insulation supports, nameplates, and locating lugs. Studs shall be limited to 1 in. (25 mm) maximum diameter for round studs or an equivalent cross-sectional area for studs of other shapes when welding in the flat position and $\frac{3}{4}$ in. (19 mm) diameter for all other welding positions. When studs are $\frac{1}{2}$ in. (13 mm) in diameter or less, postweld heat treatment, qualified welding procedures, and certified welding materials are not required.

NF-4311.2 Capacitor Discharge Welding.

Capacitor discharge welding may be used for welding temporary attachments and permanent nonstructural attachments provided:

- (a) temporary attachments are removed in accordance with the provisions of NF-4435(b); and
- (b) the energy output for permanent nonstructural attachments such as strain gages and thermocouples is limited to 125 W-sec and the minimum thickness of the material to which the attachment is made is greater than 0.09 in.; and
- (c) a Welding Procedure Specification is prepared describing the capacitor discharge equipment, the combination of materials to be joined, and the technique of application; qualification of the welding procedure is not required.

NF-4311.4 Inertia and Continuous Drive Friction Welding

- (a) Inertia and continuous drive friction welding shall not be used for fabrication of Class 1 Plate- and Shell-Type Component Supports.
- (b) The weld between the two members shall be a full penetration weld.

NF-4320 WELDING QUALIFICATION AND RECORDS

NF-4321 Required Qualifications

- (a) Each Certificate Holder is responsible for the welding done by his organization and shall establish the procedure and conduct the tests required by this Article and Section IX in order to qualify both the welding procedures and the

performance of welders and welding operators who apply these procedures.

(b) Procedures, welders, and welding operators used to join permanent or temporary attachments to support elements and to make permanent or temporary tack welds used in such welding shall also meet the qualification requirements of this Article.

(c) When making procedure test plates for butt welds, consideration shall be given to the effect of angular, lateral, and end restraint on the weldment. This applies particularly to material and weld metal of 80.0 ksi (552 MPa) tensile strength or higher and heavy sections of both low and high tensile strength material. The addition of restraint during welding may result in cracking difficulties that otherwise might not occur.

(d) NCA-3131 provides specific additional requirements when welding services are subcontracted to or through organizations not holding an appropriate Certificate of Accreditation.

NF-4322 Maintenance and Certification of Records

The Certificate Holder shall maintain a record of his qualified welding procedures and of the welders and welding operators qualified by him, showing the date and results of tests and the identification mark assigned to each welder. These records shall be reviewed, verified, and signed by any authorized individual assigned by the Certificate Holder, and they shall be accessible to the Owner and to the Inspector.

NF-4322.1 Identification of Joints for Class 1 Component Supports

(a) For Class 1 Plate- and Shell-Type, and Linear-Type Component Supports, the welder or welding operator shall apply the identification mark assigned to him by the Certificate Holder on or adjacent to all permanent welds, including fillet welds, at 3 ft (0.9 m) intervals or less, except as noted in (b) below. The marking shall be done with either blunt nose continuous or blunt nose interrupted dot die stamps. As an alternative, the Certificate Holder shall keep a record of permanent welded joints in a component support, and of the welders and welding operators used in making each of the joints.

(b) For partial penetration welds with a depth less than 1 in. and fillet welds with a throat dimension less than 1 in. in primary members, and for all welds in secondary members, the Certificate Holder need not identify the welder or welding operator who welded each joint provided:

Page 114

(1) the Certificate Holder maintains a system that will identify the welders or welding operators who made such welds on each item so that the Inspector can verify that the welders or welding operators were all properly qualified;

(2) the welds in each category are all of the same type and configuration and are welded with the same Welding Procedure Specification.

NF-4322.2 Identification of Other Joints.

For all types of Class 2, 3, and MC component supports and for all classes of piping supports and Standard Supports, the Certificate Holder shall certify that only welders and welding operators qualified in accordance with NF-4321 were used in making all welds.

NF-4322.3 Identification of Tack Welds.

The identification of welder or welding operator is not required for tack welds.

NF-4323 Welding Prior to Qualification

No welding shall be undertaken until after the welding procedures which are to be used have been qualified. Only welders and welding operators who are qualified in accordance with NF-4320 and Section IX shall be used.

NF-4324 Transferring Qualifications

The welding procedure qualifications and the performance qualification tests for welders and welding operators conducted by one Certificate Holder shall not qualify welding procedures and shall not qualify welders or welding operators to weld for any other Certificate Holder, except as provided in Section IX, QW-201 and QW-300.2.

NF-4330 GENERAL REQUIREMENTS FOR WELDING PROCEDURE QUALIFICATION TESTS

NF-4331 Conformance to Section IX Requirements

All welding procedure qualification tests shall be in accordance with the requirements of Section IX as supplemented by the requirements of this Article.

NF-4334 Preparation of Test Coupons and Specimens

(a) Removal of test coupons from the test weld and the dimensions of specimens made from them shall conform to the requirements of Section IX, except that the removal of impact test coupons and the dimensions of impact test specimens shall be in accordance with (b) below.

(b) Weld deposit of each process in a multiple process weld shall, where possible, be included in the impact test specimens. When each process cannot be included in the full-size impact test specimen at the $\frac{1}{4}t$ location required by this Section, additional full-size specimens shall be obtained from locations in the test weld that will ensure that at least a portion of each process has been included in full-size test specimens. As an alternative, additional test welds can be made with each process so that full-size specimens can be tested for each process.

NF-4334.1 Coupons Representing the Weld Deposits.

Impact test specimen and testing methods shall conform to NF-2321. The impact specimen shall be located so that the longitudinal axis of the specimen is at least $\frac{1}{4}t$, and where the thickness of the test assembly permits, not less than $\frac{3}{8}$ in. (10 mm) from the weld surface of the test assembly. In addition, when the postweld heat treatment temperature exceeds the maximum temperature specified in NF-4620, and the test assembly is cooled at an accelerated rate, the longitudinal axis of the specimen shall be a minimum of t from the edge of the test assembly. The specimen shall be transverse to the longitudinal axis of the weld with the area of the notch located in the weld. The length of the notch of the Charpy V-notch specimen shall be normal to the surface of the weld.

NF-4334.2 Coupons Representing the Heat Affected Zone.

Where impact tests of the heat affected zone are required by NF-4335.2, specimens shall be taken from the welding procedure qualification test assemblies in accordance with (a) through (c) below.

(a) If the qualification test material is in the form of a plate or a forging, the axis of the weld shall be oriented either parallel to or perpendicular to the principal direction of rolling or forging.

(b) The heat affected zone impact test specimens and testing methods shall conform to NF-2321. The specimens shall be removed from a location as near as practical to a depth midway between the surface and center thickness. The coupons for heat affected zone impact specimens shall be taken transverse to the axis of the weld and etched to define the heat affected zone. The notch of the Charpy V-notch specimen shall be cut approximately normal to the material surface in such a manner as to include as much heat affected zone as possible in the resulting fracture. Where the material thickness permits, the axis of a specimen may

Page 115

be inclined to allow the root of the notch to align parallel to the fusion line. When a grain refining heat treatment is not performed on welds made by the electroslag or electrogas welding process, the notch for the impact specimens shall be located in the grain coarsened region.

(c) For the comparison of heat affected zone values with base material values [NF-4335.2(b)], Charpy V-notch specimens shall be removed from the unaffected base material at approximately the same distance from the base material surface as the heat affected zone specimens. The axis of the unaffected base material specimens shall be parallel to the axis of the heat affected zone specimens, and the axis of the notch shall be normal to the surface of the base material.

NF-4335 Impact Test Requirements

When materials are required to be impact tested per NF-2300, impact tests of the weld metal and heat affected zone shall be performed in accordance with the following subparagraphs. Exemptions from impact testing under NF-2311(b)(9) and (10) do not apply to weld metal unless the specific weld metal used is included in Table NF-2311(b)-1 (weld metal exemptions are being developed). Exemption from impact testing of the heat affected zone of those base materials which are exempted by NF-2311(b)(9) and (10) is not permitted. The welding procedure qualification impact test specimens shall be prepared and tested in accordance with the applicable requirements of NF-2330 and NF-4334. Retests in accordance with the provisions of NF-2350 are permitted.

NF-4335.1 Impact Tests of Weld Metal

(a) Impact tests of the weld metal shall be required for welding procedure qualification tests for production weld joints exceeding $\frac{5}{8}$ in. (16 mm) in thickness when the weld is made on the surface or penetrates the base material that requires impact testing in accordance with NF-2310. In addition, such testing of the weld metal is required for the welding procedure qualification tests for any weld repair to base material that requires impact testing in accordance with NF-2310, regardless of the depth of the repair. Exemption from impact testing under NF-2311(b)(9) and (10) does not apply to weld metal of the welding procedure qualification test for either production weld joints or base material repairs unless the specific weld metal used is included in Table NF-2311(b)-1 (weld metal exemptions are being developed).

(b) The impact test requirements and acceptance standards for welding procedure qualification weld metal shall be the same as specified in NF-2330 for the base material to be welded or repaired. Where two materials which have different fracture toughness requirements are to be joined by welding, the test requirements and acceptance standards of either material may be used for the weld metal, except where otherwise specified by NCA-1280 or other parts of this Section.

(c) A Welding Procedure Specification (WPS) qualified to the impact testing requirements of Subsection NB, NC, or NE may be accepted as an alternative to the WPS impact testing requirements of this Subsection.

NF-4335.2 Impact Tests of Heat Affected Zone

(a) Charpy V-notch tests of the heat affected zone of the welding procedure qualification test assembly are required whenever the thickness of the weld exceeds $\frac{5}{8}$ in. (16 mm), and either of the base materials requires impact testing in accordance with the rules of NF-2310. Exemption of base materials by NF-2311(b)(9) or (10) does not apply to the welding procedure qualification of the heat affected zone or unaffected base material for such materials. The only exceptions to the requirements are the following:

(1) the qualification for welds in P-Nos. 1 and 3 and SA-336 F12 materials that are postweld heat treated and are made by any process other than electroslag, electrogas, or thermit.

(2) the qualification for weld deposit cladding or hard-facing on any base material.

(b) Impact testing of the procedure qualification test heat affected zone, where required by NF-4335, shall be conducted in accordance with (b)(1) through (3) and (c) below, if applicable.

(1) For tests of welding procedure qualifications for materials that require testing in accordance with NF-2331, the three Charpy V-notch heat affected zone and three Charpy V-notch unaffected base material specimens shall be tested at a temperature in accordance with NF-2331. The Charpy V-notch impact test of the unaffected base material shall meet the toughness requirements of Table NF-2331(a)-1, Table NF-2331(a)-2, Table NF-2331(a)-3, Table NF-2331(a)-4, Fig. NF-2331(a)-1, or Fig. NF-2331(a)-2 as applicable. If the average toughness value of the three heat affected zone specimens is equal to or greater than the average value of the unaffected base material Charpy V-notch specimens, the test shall be considered acceptable and the values and testing temperature shall be recorded on the Welding Procedure Qualification Record.

(2) If the heat affected zone Charpy V-notch average toughness values of (b)(1) above are less than the unaffected base material and the qualification test meets the other criteria of acceptance, the Charpy V-notch

in (b)(3) below to provide an additive temperature for the adjustment of the lowest service temperature (LST) of the base material that is to be welded in production with the welding procedure being qualified. Alternatively, the welding procedure qualification may be rewelded and retested.
